Chronic Hepatitis B Virus Infection

Dr. Wan-Long Chuang

Department of Internal Medicine, Kaohsiung Medical University Hospital, Kaohsiung Medical University Taiwan

Chronic hepatitis B virus (HBV) infection is a serious global health issue. Chronic HBV infection might lead to liver cirrhosis, hepatic decompensation, and hepatocellular carcinoma (HCC). Thus, the goal of treatment for chronic hepatitis B (CHB) is to improve survival and quality of life by preventing transmission, disease progression and HCC. Chronic HBV infection comprises four phases defined as immune tolerant phase, immune clearance phase (HBsAg-positive chronic hepatitis), inactive carrier phase, and reactivation phase (HBsAg-negative chronic hepatitis). Treating the patients with immune active chronic hepatitis B (both HBsAg-positive and negative) is recommended to decrease the risk of liver-related complications. Pegylated interferon and nucleos(t)ide analogues (NAs, including entecavir, tenofovir disoproxil fumarate and tenofovir alafenamide) are the preferred first line agents for CHB treatment. NAs are selected because of convenience, good tolerability, safety, high potency and minimal to no risk of resistance. However, NAs have no direct action on cccDNA, and long-term NAs therapy is required to maintain HBV suppression in HBsAg negative patients. There are several concerns, e.g. financial burden, adherence and willingness, for indefinite long-term NAs therapy. In addition, increase rates of HBsAg loss are observed after cessation of NAs treatment in HBsAg-negative patients. Finite NAs therapy in selected HBeAg-negative CHB becomes a recommendation. Discontinuation of NAs treatment in patients with cirrhosis is not recommended. For HBsAg-positive adults without cirrhosis who seroconvert to anti-HBe on NAs therapy, discontinue therapy after a period of consolidation treatment is suggested. NAs may be discontinued in HBeAg-negative patients without cirrhosis, who achieve long-term virological suppression. Decompensation and severe ALT flare may occur after cessation of NAs, especially in patients with liver cirrhosis. Close monitoring is warranted for the HBeAg-negative patients stopping NAs treatment. If hepatic decompensation developed, re-starting NA therapy should be given immediately. For patients with virological or clinical relapse, treatment indications for naïve CHB patients may be applied.

Epidemiology, Genotype Distribution, Prognosis and Treatment of Viral Hepatitis C and HCC in Mongolia

Dr. Oidov Baatarkhuu

Department of Infectious Diseases, Mongolian National University of Medical Sciences Mongolia

In Mongolia, morbidity from liver cancer is 68.1 per 100,000 population, which is eight times higher than the global average. This is directly associated to the higher rate of morbidity of chronic hepatitis caused by HBV, HCV and HDV. Prevalence of HCV in Mongolia was high. The predominant genotype of HCV among general populations in Mongolia is 1b. Between 2015 to 2019, 23 (0.5%) and 5,005 patients (99.5%) with genotype 1a and 1b HCV, respectively, were treated with a fixed-dose tablet containing 90 mg ledipasvir and 400 mg sofosbuvir for 12 weeks, and 81 patients (1.6%) with previous experience of interferon (IFN)-based treatment received additional 1,000 mg ribavirin. Most patients (n=5,008; 99.6%) achieved ETR and SVR12 without virologic relapse. Patients with genotype 1a showed low rates of ETR and SVR12 in only 16 patients (69.6%). There was no significant difference in SVR12 rate between patients regardless of IFN experience (n=81; 1.6%), cirrhosis (n=1,151; 22.9%), HCV RNA >6x106 IU/ml (n=866; 17.2%), or liver stiffness >9.6 kPa (n=1,721; 34.2%) (100.0%, 99.3%, 99.4%, and 99.4%, respectively). The most common AEs were headache (n=472; 9.4%), fatigue (n=306; 6.2%), abdominal discomfort (n=295; 5.9%), and skin rash (n=141; 2.8%).

Most patients had advanced HCC – 88 (45.1%) in stage III and 57 (29.2%) in stage IV. The risk factors associated with HCC development were history of acute hepatitis, chronic hepatitis, and the presence of liver cirrhosis. The most common etiology for HCC in our patients was HCV infection which is 46%, HBV infection 34%, co-infection and B and C-14% and others which is 6.0%. According to the results of our study over 65% of patients had tumor size more than 5 cm. Single tumors was only found in 15%. The mean AFP level was 196 ng/ml. In 18.5% distant metastasis existed. Regarding tumor stage, there was no patient with stage 1. In addition, the most patients with HCC were diagnosed in advanced stage. In Mongolia HCC treatment modality is very limited. According to the results of our study, 14% of patients received surgical resection, and their survival was the best. 11.8% of patients received RFA and their survival was 11 months. About 55% of patients received TACE and their median survival was 17 months. The prognosis for patients with supportive care was very poor with a median survival of 5 months. Regarding cause of death, about 50% patients died of HCC progression and the others died of liver failure or GI bleeding. Regarding early detection of HCC in Mongolia, AFP is available in all hospitals except inter- soum and soum’s hospitals.

HBV “Viral Elimination” in Asia-Pacific region-current status and challenges

Dr. George Lau

Humanity and Health Clinical Trial Center, Humanity and Health Medical Group, Hong Kong SAR, China

In 2016, the World Health Assembly approved the World Health Organisation (WHO) Global Health Sector Strategy on HBV, with a goal of “elimination of HBV as a major health threat” by 2030, targeting a 90% reduction in new HBV infection and a 65% reduction in mortality due to HBV. However, recent data suggested deviation from these goals, with over 890,000 new HBV cases in 2019-2020 and a global HBV-related mortality rate exhibiting minimal change (annualized rate of change < 0.4% between 2015-2019). Two-thirds of these HBV-related mortality occurred in Southeast Asia and Western Pacific regions. In real-world clinical practice, two major barriers hinder a significant reduction of disease burden due to HBV infection: lack of awareness (among public and policy makers) and under-treatment of those with a risk of developing complications related to HBV infection, with effective anti-viral therapy, namely high resistant barrier nucleos(t)ide analogues (NAs including tenofovir, entecavir, tenofovir alafenamide) or pegylated interferon or both, which have all been demonstrated to enable a drastic reduction in HBV-related morbidity and mortality with long-term follow-up. With the recent availability of low-cost rapid diagnostic tests for HBsAg with negligible false-negative results, which can be utilised for large-scale screening and diagnosis of HBV infection, only an estimated 15-30% of chronic HBV infection have been diagnosed. Hence, to further decrease global viral
and disease burden, it is of paramount importance to identify all patients with CHB infection and timely initiate effective antiviral therapy for them. In the meantime, increase public awareness to access hepatitis B test is essential. On the other hand, in accordance with the existing regional treatment guidelines, it was estimated that less than one-tenth of those CHB patients indicated for treatment received anti-HBV therapy. There is also a recent call to expand treatment criteria beyond existing guidelines to extend therapeutic benefits to more patients with CHB infection. Indeed, a cost-effectiveness analysis of expanded antiviral treatment for CHB infection, based on decision-tree Markov state-transition model, suggested expanding treatment to HBV-infected patients with ALT thresholds of 30 U/L and 19 U/L for males and females, with 80% treatment coverage for HBsAg-positive individuals aged 18–80 years. This expanded antiviral treatment with a modified ALT threshold, coupled with lower generic drug costs and a revised medical insurance subsidization policy, particularly in HBV-endemic countries like China, could reduce HBV-related complications and deaths to support the global target of 65% reduction in HBV-related death. With the recent surge of prevalence and emerging association of Metabolic dysfunction-associated fatty liver disease as a comorbidity factor for CHB patients, future treatment guidelines likely need to be modified accordingly. In future, we believe that a collaborative effort of all authoritative liver societies to revise and expand HBV treatment guidelines considering the drastically reduced cost of anti-viral therapy, along with universal screening for HBsAg positivity, will contribute to a meaningful reduction in disease burden due to HBV infection in Asia-Pacific region.

Post-Graduate Program (Hepatitis B)

PG1-4

Role of HBcrAg in Predicting Long-Term Outcomes for Patients with Chronic Hepatitis B

Dr. Tai-Chung Tseng

Department of Medical Research, National Taiwan University Hospital, Taipei Taiwan

Hepatitis B virus (HBV) infection poses a significant global health challenge. Individuals with chronic hepatitis B (CHB) infection face diverse adverse events, including the risk of severe hepatitis flare, potentially leading to acute-on-chronic liver failure (ACLF), cirrhosis, hepatocellular carcinoma (HCC), and other complications. Conversely, some individuals experience favorable outcomes, such as spontaneous clearance of hepatitis B surface antigen (HBsAg) or hepatitis B e antigen (HBeAg). Serum hepatitis B core-related antigen (HBcrAg) quantification is a valuable biomarker for covalently closed circular DNA (cccDNA) levels, providing crucial information for clinical management. In the early phase of chronic HBV infection, HBeAg-positive patients are considered "immune-tolerant" due to active viral replication without significant liver damage. Our recent findings revealed that elevated HBcrAg levels (>100 million U/mL) correlate with a reduced likelihood of spontaneous HBeAg seroclearance in HBeAg-positive patients, particularly in the immune-tolerant subgroup. This insight aids physicians in deciding whether to initiate antiviral treatment or await spontaneous HBeAg seroclearance. Functional cure, indicated by HBsAg seroclearance, is associated with lower HBcrAg levels, especially in those with HBsAg levels >1000 IU/mL. The reduction of HBcrAg precedes the decline of HBsAg, suggesting the need to target cccDNA for successful treatment. A delayed decline in HBsAg levels suggests additional agents targeting HBsAg derived from integrated HBV DNA may be necessary for achieving functional cure.

Current guidelines recommend antiviral therapy for immune-active CHB patients but not for inactive CHB patients due to their different HCC risk. However, more than half of the HBeAg-negative CHB patients find themselves in the "grey zone" (GZ). We developed a novel GZ-HCC risk score (EXPLORE) considering age, sex, platelet count, ALT levels, and hepatitis B core-related antigen. This is the first risk prediction model demonstrating that an HBcrAg-based HCC score outperforms HBV DNA-based HCC scores in HBeAg-negative GZ patients. The model has been validated in an independent Japanese cohort. Furthermore, we propose a GZ-HCC score of >8 to categorize GZ patients into high- and low-risk groups, aligning their HCC risk levels with those of immune-active CHB and inactive CHB patients, respectively. In conclusion, HBcrAg is a valuable biomarker for predicting clinical outcomes, and its integration with various viral markers enables customized therapeutic approaches for CHB patients with distinct risk profiles.

Post-Graduate Program (Hepatitis C)

PG2-4

Dr. Yoshiyuki Ueno

Department of Gastroenterology, Yamagata University Faculty of Medicine Japan

Viral hepatitis infection has been a great threat to human health globally. Although remarkable breakthrough has been made in the past several decades for prevention and treatment of viral hepatitis, still this infectious disease is increasing its risk. Actually, 905,700 people were diagnosed with and 830,200 people died from liver cancer in 2020. Moreover, the number of new cases and deaths from liver cancer could rise by >55% by 2040. Thus, HCC remains to be global risk for next decades. Of course, viral infection is a major cause of HCC in many countries. With this line, WHO aimed to set the global elimination of viral hepatitis by 2030. WHO's global hepatitis strategy, endorsed by all WHO Member States, aims to reduce new hepatitis infections by 90% and deaths by 65% between 2016 and 2030. However, except for few countries or regions, our actual achievement has been behind the track. In this session, our current status and future strategy will be summarized to keep our mission on the planned goals.

Post-Graduate Program (MAFLD)

PG3-2

Etiology and Usefulness of MAFLD in the Asian-Pacific region

Dr. Takumi Kawaguchi

Division of Gastroenterology, Department of Medicine, Kurume University School of Medicine. Japan

MAFLD is a major public health problem in the Asian-Pacific region. Excess energy intake and a sedentary lifestyle are major causes of hepatic steatosis. These unhealthy lifestyles also cause the accumulation of lipids in visceral adipose tissue, leading to adipose tissue inflammation. Adipose tissue produces proinflammatory cytokines including TNF-α, IL-1β, and IL-6, which flow into the liver through the hepatic artery. These adipose tissue-derived factors promote the development of MAFLD. Besides visceral adipose tissue, the gut is a major etiological organ of MAFLD. Dietary factors including excess fructose intake induce dysbiosis, leading to low-grade intestinal inflammation and an impairment of gut barrier function called leaky gut. A leaky gut facilitates the translocation of lipopolysaccharides and microbial metabolites to the
liver through the portal vein. This influx causes the production of pro-inflammatory cytokines and attracts immune cells through activation of Kupffer and liver sinusoidal endothelial cells in the liver. Risk factors for MAFLD in Asians are like those in Westerners. In addition, a feature of Asians is non-obese MAFLD. In non-obese Asian individuals, possible etiologies of MAFLD are the following: visceral obesity, dysbiosis, sarcopenia, hypothyroidism, hypopituitarism, and hyperuricemia. Furthermore, another possible etiology is genetic predisposition including polymorphism in PNPLA3 (patatin-like phospholipase domain-containing protein 3), TM6SF2 (transmembrane 6 superfamily member 2), GCKR (glucokinase regulator), MBOAT7 (membrane bound O-acyltransferase domain containing 7), and HSD17B13 (hydroxysteroid 17-beta dehydrogenase-13).

MAFLD is a disease concept that actively encloses high-risk patients through inclusion criteria. In fact, various Asian-Pacific clinical studies demonstrated that MAFLD identifies patients with significant hepatic fibrosis and at high risk of HCC. In addition, MAFLD has been reported to identify patients at higher risk for atherosclerotic cardiovascular disease better than NAFLD. The superiority of MAFLD over NAFLD seems to be due to the presence of metabolic dysfunction rather than moderate alcohol consumption. Furthermore, MAFLD is more associated with various extrahepatic diseases including reflux esophagitis, colorectal adenoma, the recurrence of esophageal squamous cell carcinoma, chronic obstructive pulmonary disease (COPD), and psoriasis rather than NAFLD. Thus, MAFLD is useful to identify patients at risk of both liver-related events and extra-hepatic events. In this session, we will introduce the etiology of Asian-Pacific MAFLD according to the APASL guidelines. I also mention the impact of MAFLD on the identification of patients at risk of hepatic events as well as extra-hepatic events in the Asia-Pacific region.

Hepatocellular Carcinoma Risk prediction score (GES) in chronic hepatitis C patients with compensated advanced chronic liver disease (cACLF) after achieving SVR

Dr. Gamal Shiba
Gastroenterology and Hepatology Dept., Faculty of Medicine, Mansoura University, Egyptian Liver Research Institute and Hospital (ELRIAH) Egypt

Introduction: We designed and validated a scoring system known as the General Evaluation Score (GES) for Hepatocellular Carcinoma (HCC) risk stratification. Our objective was to assess the efficacy of this score within a substantial prospective cohort comprising individuals with cured hepatitis C, with compensated advanced chronic liver disease, and achieved a sustained virological response following direct-acting antivirals.

Methods: This prospective study, conducted at the Egyptian Liver Research Institute and Hospital between January 2018 and October 2019, enrolled 463 consecutive patients with advanced fibrosis (≥F3) who attained sustained virological response. Prior to antiviral therapy initiation, all patients underwent abdominal ultrasound and multislice computed tomography for HCC surveillance. Subsequent follow-ups occurred every 6 months post-treatment, utilizing ultrasonography, alpha-fetoprotein, and additional multislice computed tomography every 12 months.

Results: Of the 463 patients included, 197 (42.5%), 114 (24.6%), and 152 (32.8%) were stratified as having low, intermediate, and high-risk scores, respectively, before treatment initiation. The incidence rate of HCC was 2.61 per 100 person-years (95% CI = 1.73–3.80), with 25 cases developing HCC during the follow-up period. The respective HCC incidence rates in the low, intermediate, and high-risk groups were 0.97% (95% CI: 0.31–2.34), 1.68% (95% CI: 0.53–4.05), and 5.57% (95% CI: 3.35–8.74). A significant positive correlation was observed between higher risk scores and increased HCC incidence (p < 0.001). Harrell’s c-statistic for this model was 0.728.

Conclusion: This prospective study underscores the predictive capability of GES in anticipating HCC occurrence and effectively categorizing patients into low, intermediate, and high-risk groups.

Post-Graduate Program (ACLF)
PG5-1

Prognostic predictors in patients with Acute-on-chronic liver failure (ACLF)

Dr. Teerha Piratvisuth
NKC Institute of Gastroenterology and Hepatology Faculty of Medicine, Prince of Songkla University Thailand

Acute-on-chronic liver failure is a severe form of acutely decompen- sated cirrhosis with high mortality rate, 28-day mortality rate >20%. Prognostic predictors can guide the optimal strategies for managing individual patient properly. The number of organ system failure is associated with severity and mortality of ACLF-patients. The ACLF grades, based on the number of organ failures (liver, kidney, brain, coagulation circulation, respiration) enable to categorize patients with a range of 28-day and 3-month mortality risks. There are currently a few scoring system for predicting mortality rate in patients with ACLF. The CLIF-C ACLF score was developed by combining the CLIF-C score with age and white cell count for predicting 28-day and 90-day mortality better than those of the MELD score, MELD-Na score and Child-Pugh score. The AARC score was developed for patients with ACLF diagnosed using the APASL for predicting short-term mortality. The NACSELD only based on failure of 4 organ systems (brain, kidney, circulation, reparation) defined by the physicians’ response to the problem. The NACSELD may underestimates the risk of death in patients with ACLF. The COSHH Score was developed for patients with HBV-related ACLF. The newly proposed models and nomograms for predicting prognosis in patients with ACLF have shown some improvement on the CLIF-C ACLF score, but they require further validation. Inflammation severity has been shown as the most important predictor of ACLF.

PG6-1

Emerging non-invasive methods for evaluation of cirrhotic portal hypertension

Dr. Xiaolong Qi
CHESS Center, Center of Portal Hypertension, Department of Radiology, Zhongda Hospital, School of Medicine, Southeast University China

Clinically significant portal hypertension (CSPH) is associated with symptomatic gastro-oesophageal varices (GOV), the development of hyperdynamic circulation, and patients with compensated advanced chronic liver disease at risk of clinical decompensation. Hepatic venous pressure gradient (HVPG) measurement and esophagogastroduodenoscopy are the gold standard methods for assessing CSPH (HVPG ≥10 mm Hg) and GOV, respectively. However, they are limited by their invasiveness in clinical practice. In recently years, there are a lot of new technologies focuses on the development of non-invasive approaches to the diagnosis and serial monitoring of portal hypertension.
Imaging techniques used for portal hypertension include ultrasound, computed tomography (CT) and magnetic resonance (MR). Elastography techniques measure liver and spleen stiffness by quantifying the velocity of an induced shear wave, including transient elastography, point-shear wave elastography, and two-dimension shear wave elastography; and MR elastography. Liver stiffness measurement has been proved to be sufficiently accurate to identify CSPH and safe to screen high-risk varices combined with platelet count in clinical practice. Laboratory tests and serum markers need to be interpreted critically because some of their individual components can be affected by a variety of comorbidities. Artificial intelligence (AI) has made great strides in the field of medicine. Information of CT and MR imaging can be integrated and applied to detection of cirrhosis and portal hypertension by AI.

In summary, a wide spectrum of novel non-invasive tests have emerged and represent a major advantage in the assessment of portal hypertension. However, there are still many challenges to integrating non-invasive screening methods into clinical practice, and more data are needed to establish consensus on standard practice and implementation.

Current Endoscopic Gastrointestinal Interventions and Management

Dr. Hideki Kobara
Department of Gastroenterology and Neurology, Faculty of Medicine, Kagawa University Japan

Endoscopic submucosal dissection (ESD) has been an attractive minimally invasive surgery during the past two decades. Currently, pure Endoscopic Full-Thickness Resection (EFTR) is focused as next-advanced technique. Meanwhile, post-ESD or EFTR defects, and iatrogenic perforation must be carefully managed to prevent and rescue adverse events.

Here, I would like to introduce these current gastrointestinal interventions and our ongoing research.

Post-Graduate Program (PH)
PG6-3

Role of HVPG in the management of portal hypertension

Dr. Hitoshi Maruyama
Department of Gastroenterology, Juntendo University Japan

Cirrhosis is the most advanced stage of chronic liver disease. It is accompanied with a risk of developing serious complications, including variceal bleeding, ascites, icterus, and hepatic encephalopathy. These events limit quality of life and long-term outcomes, therefore, patients with these conditions need to be properly monitored.

Hepatic venous catheterization is a safe and an established technique which enables measurement of hepatic venous pressure gradient (HVPG) by either jugular approach or femoral approach. Hepatic venogram is useful to demonstrate the typical appearance of cirrhosis and non-cirrhotic portal hypertension, which could be obtained by using either iodinated contrast material or carbon dioxide.

Portal hypertension is the principal pathophysiology of cirrhosis, and a HVPG is a representative marker for the severity of the condition. A HVPG of 10 to 12 mmHg is the threshold level for the development of esophageal varices, ascites, and the occurrence of variceal bleeding, and a HVPG higher than 16 mmHg suggests an increased risk of death. Moreover, a HVPG higher than 20 mmHg is the best independent prognostic marker for acute variceal bleeding, and thus indicates the presence of much more severe status. In addition, a HVPG is an effective marker to offer the treatment direction of TIPS for variceal bleeding in cirrhosis, and to predict the prognosis after TIPS placement for refractory ascites. Thus, hepatic venous catheterization has a wide range of role in the management of portal hypertension. This presentation overviews recent studies regarding HVPG and summarizes the evidences.

Post-Graduate Program (HCC)
PG7-1

Discovery of therapeutic and biomarker for HCC through basic and translational research of tumor microenvironment

Dr. Takahiro Kodama
Dept. Gastroenterology and Hepatology Osaka University Graduate School of Medicine Japan

HCC is a dismal disease with the third highest mortality rate among all cancer types. Its molecular entity is very complex and further clarification of its heterogeneous nature is required for prognostic improvement. With the progress of next-generation sequencers over the past decade, the genomic and epigenomic abnormalities in HCC have been well-documented with a large number of cases, and the whole picture has become clear. On the other hand, the recent development of innovative technologies such as single-cell analysis and spatial omics analysis has begun to open a new era in cancer research. In the tumor microenvironment, not only cancer cells but also various immune cells and stromal cells exist, and these form a complex network that leads to cancer formation and progression. In recent years, various drugs have been developed and made available for HCC. Importantly most of them, such as angiogenesis inhibitors and immune checkpoint inhibitors, target the tumor microenvironment rather than the cancer cells themselves, indicating the importance of understanding cancer as such an ecosystem to truly overcome cancer. One of the treatment goals of HCC therapy is personalized therapy with a variety of molecular-targeted drugs and their efficacy biomarkers. Recent advancement in HCC pharmacotherapy allows us to utilize 8 different therapeutic regimens but the efficacy of each drug is still limited. Further research efforts to discover novel drug targets and develop efficacy biomarkers are desired in the HCC field. In this presentation, I would like to share recent knowledge of the HCC tumor microenvironment and show our latest discoveries of therapeutics and biomarkers for HCC through basic and translational research. I also would like to discuss with the audience the future perspective of HCC research.

Post-Graduate Program (HCC)
PG7-3

Post-Graduate Program (HCC): Treatment guidelines update

Dr. Yi-Hsiang Huang
Taiwan Liver Cancer Association (TLCA), Institute of Clinical Medicine, College of Medicine, National Yang Ming Chiao Tung University, Healthcare and Services Center, Taipei Veterans General Hospital Taiwan

HCC is prevalent in Asia Pacific countries and its incidence is expected to rise in the next decade. The treatment of HCC depends on tumor stage and liver function reserve. BCLC is widely adopt as the
staging system for HCC in most countries. The goal of treatment for early stage HCC is to curative resection or ablation for the tumor and avoid recurrence as possible. Several strategies have been established to be able to decrease the risk of recurrence, such as antiviral treatment for underlying chronic hepatitis B or C, and most recently adjuvant immunotherapy for high risk patients. For intermediate stage HCC, TACE is no longer the only option. Due to the heterogenous nature of BCLC B tumors, the outcome of TACE is varied depending on tumor burden and radiologic patterns. Due to the advance of systemic therapy, some patients with intermediate stage HCC have the potential to be curative conversion by atezolizumab/bevacizumab followed by locoregional treatment or surgical resection. TACE combined with immunotherapy, lenvatinib or sorafenib may also prolong the survival for BCLC B HCC. For advanced stage HCC, systemic therapy is the key treatment. Immunotherapy either by atezolizumab/bevacizumab, or tremelimumab/durvalumab is the standard of care if there is no contra-indication for immunotherapy. Although there is no phase 3 clinical trial to support the optimal treatment as 2L after immunotherapy, different mechanism of action and tolerability of adverse event are the key considerations for the choice of subsequent treatment

Post-Graduate Program (HCC)  
PG8-4  

Post-Graduate Program (HCC) Systemic therapy  
Dr. Masafumi Ikeda  
Department of Hepatobiliary and Pancreatic Oncology at the National Cancer Center Hospital East Japan  
Systemic therapy has become mainstream for hepatocellular carcinoma (HCC), with the development of molecular-targeted agents, such as sorafenib and lenvatinib as first-line treatment and regorafenib, ramucirumab and cabozantinib as second-line treatment, and of immunotherapies, such as atezolizumab plus bevacizumab, durvalumab plus tremelimumab and durvalumab monotherapy. In Japan, a total of 9 regimens are now available for unresectable HCC. Combined immunotherapies are firstly selected if patients have no contraindication for immunotherapies, such as autoimmune diseases. Molecular-targeted therapies are firstly selected if patients have no contraindication for immunotherapies, such as autoimmune diseases. Molecular-targeted therapy is selected when immunotherapy is not indicated or proves ineffective. And, it is necessary to select the appropriate treatment taking into consideration the patients’ clinical condition, expected treatment efficacy, and adverse effects of the treatment.

The indications for systemic therapy are currently expanding, although advanced-stage HCC was a good indication for systemic therapy previously. Systemic therapy is indicated for intermediate-stage HCC that is trasarterial chemoembolization (TACE) refractory or TACE unsuitable. When performing non-curative-intent TACE, combination therapy of TACE and systemic therapy is expected to be a future treatment strategy, because phase III trial of TACE with durvalumab plus bevacizumab vs. TACE with durvalumab plus placebo vs. TACE with placebo (EMERALD-1) was press-released to meet the primary endpoint for progression-free survival. Furthermore, the indication might be expanding for early-stage HCC, because perioperative adjuvant therapy of atezolizumab plus bevacizumab demonstrated significantly better recurrence-free survival after curative surgical treatment or ablation (IMbrave050). Therefore, systemic therapy is now available for any stage of the disease. While previously, local therapies used to be the main treatment strategy for HCC, systemic therapy in combination with local therapies is being actively tried at present. Systemic therapy is currently promising topics of development of novel treatments for HCC.

APASL Targets for this Century  
TC1-2  

APASL clinical practice guideline on systemic therapy for hepatocellular carcinoma- 2024  
Dr. George Lau  
Humanity and Health Clinical Trial Center, Humanity and Health Medical Group, Hong Kong SAR, China  
Since the inception of the first Asian-Pacific Association for the study of liver (APASL) hepatocellular carcinoma (HCC) working party in 2007 and the publication of its first guideline published in 2010 and then revised in 2017, major advances in systemic therapy for hepatocellular carcinoma (HCC) have been made. Despite the availability of effective HCC surveillance and preventive measures, most of the HCC still present at advanced stage as reflected by the high mortality-incidence ratio across Asian-Pacific region. Most of these patients diagnosed with HCC are therefore beyond curative measures such as surgical resection, local ablation or liver transplantation. Even for those patients who are eligible to have curative measures in accordance to various HCC treatment guidelines, recurrence is still a very common clinical problem. The major etiology of the HCC in Asian-Pacific region are chronic hepatitis B and C infection, compounded by the recent rise of metabolic dysfunction-associated fatty liver diseases (MAFLD). In countrylike China, the incidence of HCC is not rising but accounts for close to half of the global annual cases. Most if not all are related to chronic hepatitis B infection.

In the recent few years, new targeted therapy and immune-checkpoint inhibitors have been registered as systemic therapy for hepatocellular carcinoma either as first-line or second-line therapy for unresectable or not eligible for locoregional therapy. The gravity of chronic hepatitis B and C as etiology of hepatocellular carcinoma in Asia-Pacific region, is of great relevance as the response to immune-checkpoint inhibitors are much higher, as compared to targeted therapy. Recently, new data is also emerging with the use of systemic therapy to prevent HCC after curative attempt with resection or local ablation therapy. The purpose of this clinical guideline is to provide an up-to-date recommendation based on clinical evidence and experience from regarded key opinion leaders in the field of hepatocellular carcinoma. Three key questions will be addressed, namely (1) which patients with HCC should be considered for systemic therapy? (2) which systemic therapy should be used? and (3) how should a patient planned for systemic therapy be managed and monitored?

Looking ahead: MAFLD in the APASL region  
Dr. George Jacob  
Storr Liver Centre, The Westmead Millennium Institute for Medical Research, Westmead Hospital and University of Sydney Australia  
At its core, APASL’s main objective is to advance the science and practice of Hepatology, particularly for patients in the Asia Pacific region. In 2024, the APASL pillars focussed on viral hepatitis elimination, liver cancer, acute on chronic liver failure through AARC, the APASL-ACLF Research Consortium (AARC), and MAFLD, through the APASL-MAIDEN (Metabolic fatty liver Disease consortium; maiden-apsl.com) consortium. While we have made tremendous progress over the past decades through vaccination against hepatitis B, curative treatments for hepatitis C and suppressive treatments for hepatitis B, the frontier that has now received the attention it deserves is MAFLD, projected to be the most common liver disease worldwide, with Asia...
at its epicentre. The Asian Pacific region harbours a majority of the world’s population, with just two countries, India and China the most populous. The region is witnessing an economic transformation becoming the engine for global growth, but at the same time, being home to a rising global burden of obesity and type 2 diabetes. These diseases drive a systemic physiological response driven by insulin resistance, which in the liver drives fat deposition (MAFDL) and in pre-disposed individuals, a low grade chronic inflammatory response that leads to hepatic inflammation (steatohepatitis), cirrhosis and its feared complications, liver failure and liver cancer (both hepatocellular and cholangiocarcinoma). However, MAFDL is more than a liver disease and is just one part of systemic metabolic dysfunction, the harbinger of cardio-reno-vascular disease, diabetes and extrahepatic cancer. Managing the consequences of these diseases, a very large proportion of health budgets in Asian Pacific countries will be consumed unless effective policy action and settings are undertaken. While effective pharmacotherapies for weight loss and type 2 diabetes are emerging or are clinically approved, at a population level, they are expensive. Hence, preventive frameworks focussing on food quality, food quantity and physical activity needs to be prioritised. For those with MAFDL, clinical pathways to identify those with significant liver disease, referral pathways to tertiary care and treatment is required. APASL as the peak body for Liver Disease in our region is well placed to lead these initiatives by developing pan-national educational toolkits that can subsequently be individualised to cater to local needs.

HBV Challenges for Elimination of CCC HBV DNA

Clinical utility of novel biomarkers for hepatitis B infection

Dr. Man-Fung Yuen
Department of Medicine, School of Clinical Medicine, The University of Hong Kong Hong Kong SAR, China

During the process of viral replication of hepatitis B virus (HBV) from the viral template, the covalently closed circular (ccc) DNA, there are production of viral nucleic acids, namely, HBV DNA and intermediate HBV RNA. Viral translation activities of different genomic regions of HBV also produce several mRNAs which would be transcribed into various viral antigens including HBsAg, HBeAg and HBcAg. Of note, HBcAg can also be generated from integrated HBV DNA. In the past, conventional measurements of serum viral biomarkers in patients with chronic hepatitis B (CHB) mainly include HBsAg, HBeAg and HBV DNA. It has been shown that measuring these conventional biomarkers have clinical significance for the disease monitoring and treatment. For example, serum HBsAg has predictive value for spontaneous and treatment-induced HBsAg seroclearance. However, existing nucleos(t)ide analog (NA) treatment has negligible effects on HBsAg level. Whereas baseline HBsAg levels before initiation of novel treatment predicts an increase in HBsAg ratio and non-phosphorylated forms of HBcAg in the serum. Clinical usage of this new assay is being actively explored. HBV RNA is another novel HBV biomarker; its roles are overlapping with HBcAg in some areas. HBV RNA measurement correlates with disease outcome, treatment response and HBV reactivation. HBV RNA seems to be prominently useful in patients who are on NA treatment. In conclusions, development of novel HBV biomarkers is able to provide additional and essential disease assessment and treatment guidance for CHB disease. Standardization and increased availability of these assays are highly encouraged.

HBV Challenges for Elimination of CCC HBV DNA

HBV1-2

Identification of host factors that were essentially involved in hepatitis B virus persistence

Dr. Masao Honda
Department of Clinical Laboratory Medicine Kanazawa University Graduate School of Medical Science Japan

Background & aims: Hepatitis B virus (HBV) infection is difficult to cure owing to the persistence of covalently closed circular viral DNA (cccDNA). We performed single-cell transcriptome analysis of newly established HBV-positive and HBV-negative hepatocellular carcinoma cell lines and found host factors that were crucially involved in HBV persistence.

Methods: The cccDNA levels were measured by Southern blotting and real-time detection polymerase chain reaction in various hepatocytes including PXB cells by using an HBV-infected model. HBV capsid was investigated by super-resolution microscopy, proximity ligation assay, and time-lapse analysis. The binding partners of host factors were examined by liquid chromatography-tandem mass spectrometry, immunoblotting, and enzyme-linked immunosorbent assay.

Results: We found that four factors that were crucially involved in HBV persistence. One of the four host factors was dedicator of cytokinesis 11 (DOCK11), known as a guanine nucleotide exchange factor (GEF) for Cdc42. The cccDNA levels were strongly increased by DOCK11 overexpression and repressed by DOCK11 suppression. Interestingly, DOCK11 functionally associated with retrograde trafficking proteins in the trans-Golgi network (TGN), Arf-GAP with GTPase domain, ankyrin repeat, and pleckstrin homology domain-containing protein 2 (AGAP2), and ADP-ribosylation factor 1 (ARF1), together with HBV capsid, to open an alternative retrograde trafficking route for HBV from early endosomes (EEs) to TGN and then to the endoplasmic reticulum (ER), thereby avoiding lysosomal degradation. Clinically, DOCK11 levels in liver biopsies from patients with chronic hepatitis B were significantly reduced by entecavir treatment, and this reduction correlated with HBV surface antigen levels.

Conclusions: HBV uses a retrograde trafficking route via EEs-TGN-ER for infection that is facilitated by DOCK11 and serves to maintain cccDNA. Therefore, DOCK11 is a potential therapeutic target to prevent persistent HBV infection.

HBV1-3

Analysis of HBsAg and cccDNA reduction by nucleotide analogue and pegylated interferon combination therapy

Dr. Masataka Tsuge
Department of Gastroenterology, Graduate School of Biomedical & Health Sciences, Hiroshima University Japan
Once HBV enters human hepatocytes, its genome is carried into the nucleus where it forms covalently closed circular DNA (cccDNA), similar to a minichromosome. This translocation of the HBV genome into the nucleus makes it difficult for either the host immune response or present antiviral therapies to eliminate the virus. Combined antiviral treatment using pegylated interferon (PEG-IFN) and nucleotide/nucleoside analogues (NAs) are currently used to suppress cccDNA levels in patients with chronic HBV infection. Although add-on therapy and sequential therapy using PEG-IFN have been attempted in chronic hepatitis B patients following long-term NA therapy, it has not been clarified which PEG-IFN therapy is most effective in reducing HBs antigen (HBsAg) levels. In this study, we investigated the change in HBsAg levels after PEG-IFN therapy (approval number: E-704) and conducted basic research on reduction of cccDNA in liver tissues by NA plus PEG-IFN combination therapy. The subjects included 21 HBsAg-negative chronic hepatitis B patients who had undergone NA therapy for more than one year at our hospital and related facilities. Sequential or add-on therapy using PEG-IFN was performed, and HBsAg levels were measured for up to 5 years after completion of PEG-IFN treatment. Furthermore, we performed add-on therapy on HBV-infected human hepatocyte chimeric mice and examined changes in intrahepatic HBV RNA and cccDNA levels. HBsAg level was reduced by a median of 0.48 Log IU/mL during PEG-IFN therapy. More than 1 Log HBsAg reduction was observed in 9 patients 5 years after the completion of PEG-IFN therapy. Five patients with sequential therapy and 2 patients with add-on therapy achieved HBsAg loss. ALT elevation during PEG-IFN therapy and lower serum IL-8 level at the end of PEG-IFN therapy contributed to HBsAg reduction at 1 year after completion of PEG-IFN therapy (P=0.038, P=0.044). ALT elevation during PEG-IFN therapy, platelet levels at the start of PEG-IFN therapy, and serum IL-8 levels at the end of PEG-IFN therapy were associated with HBsAg reduction at 5 years after PEG-IFN therapy (P=0.034, P=0.049, P=0.041). To confirm high HBsAg reduction by IFN treatment, we measured intrahepatic HBV markers using HBV-infected chimeric mice with add-on therapy. After add-on therapy, intrahepatic HBV RNA and cccDNA levels had decreased to less than 1/50 and 1/2 of that in untreated mice, respectively. Sequential therapy might be more effective in reducing HBsAg levels than add-on therapy, but add-on therapy has the potential to reduce intrahepatic cccDNA levels.

HBV Novel Detection Methods for HBV Markers

**HBV2-1**

**Rethinking the disease status of chronic hepatitis B: The roles of novel detection methods for HBV markers**

**Dr. Atsumasa Komori**

Department of Treatment for Intractable Disease, Division of International Medical Cooperation, Clinical Research Center, and Department of Hepatology, National Hospital Organization NHO Nagasaki Medical Center Japan

Beyond widely available diagnostic tests used in the management of HBV, that includes quantitative (q) HBV DNA and qHBsAg, novel detection methods for HBV markers are scrutinized for their clinical utility in recent years, aiming to rigorous evaluation of functional cure (undetectable HBsAg and HBV DNA) and to appropriate risk stratification for hepatocellular carcinoma (HCC). Among them, ultrasensitive measurement of HBsAg or HBcrAg by iTACT (Immunoassay for Total Antigen including Complex via preTreatment) technology and specific detection of middle (M) protein in HBsAg of genotype C by the antibody against O-glycosylated residue (HBsAgGi) are promising candidates.
HBsAg in the culture supernatant, especially those with potent anti-HBV activity, to obtain SAG compounds (SAG-comp; IC50~1.4 nM). The SAG-comp, a novel anti-HBV therapeutic agent, is an orally available and well-tolerated drug that potently suppresses HBsAg. It can destabilize HBV-RNA and may induce functional cure in combination therapy with NA. In such anti-HBV therapies aiming for functional cure, monitoring HBcAg and HBsAg would be useful for determining the therapeutic efficacies of novel anti-HBV drugs targeting HBV-RNA and its related-proteins. In conclusion, HBcAg and HBsAg, especially when measured by the recently developed iTACT assay, may be the most appropriate surrogate marker, over other HBV biomarkers, for the management of CHB patients.

HBV Novel Detection Methods for HBV Markers

HBV RNA – is it ready for clinical use?

Dr. Henry Lik Yuen Chan
Department of Internal Medicine, Union Hospital Faculty of Medicine, The Chinese University of Hong Kong Hong Kong SAR, China

Pregenomic HBV RNA is a new diagnostic biomarker to monitor the disease of chronic hepatitis B. It reflects the transcriptional activity of intrahepatic cccDNA. In untreated patients, the level of HBV RNA correlates well with other HBV viral markers including HBV DNA and HBcAg. The key clinical usage of HBV RNA is among patients under nucleos(t)ide analog treatment, as HBV DNA is often undetectable in these patients. The presence of HBV RNA indicates residual viral activity, which is associated with an increased risk of hepatocellular carcinoma. The value of HBV RNA to predict virological relapse after stopping nucleos(t)ide analog is controversial, but detectable HBV RNA is found to associate with an increased risk of hepatitits flare. With the development of new therapeutics for chronic hepatitis B, HBV RNA can be a biomarker for target engagement particularly for capsid assembly inhibitors.

HBV Functional Cure of CH-B in Real World

HBV Functional Cure of CH-B in Real World

Advancing towards the functional cure of HBV

Dr. Motoyuki Otsuka
Department of Gastroenterology and Hepatology, Okayama University Japan

As a therapeutic goal for the treatment of hepatitis B, the 'clearance of HBs antigen' is currently the goal. However, this achievement is challenging with the nucleoside analogs, which are widely used. Consequently, there is an active pursuit in the development of novel therapeutic agents. At present, the most promising approach is RNAi-based drugs, which can decrease the HBsAg levels. As an alternative approach, we focused on compounds that inhibit the degradation of the host factor Smc5/6 protein, which plays a role in suppressing the transcription of viral RNA from cccDNA. Through a screening of compounds, we identified two compounds that suppress the degradation of Smc5/6 protein complexes and show potential in suppressing the expression of viral RNA and viral proteins. Both compounds are utilized in the treatment of diseases other than HBV, raising expectations for their practical application through so called “drug repositioning”. Simultaneously, this inhibition of Smc5/6 protein degradation suggests a potential link to the suppression of HBV-related oncogenesis. This presentation will provide an overview of these mechanisms and discuss remaining challenges in HBV treatment after achieving a functional cure.

HBV Functional Cure of CH-B in Real World

Functional cure of CH-B in Real World

Dr. Qin Ning
State Key Laboratory for Diagnosis and Treatment of Severe Zoonotic Infectious Diseases, Department and Institute of Infectious Disease, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology. Clinical Study Centre for Viral Hepatitis, Hubei Province China

Evidence from randomized controlled trials (RCT), e.g. OSST, Endeavor and Anchor study, as well as other relevant clinical studies has shown that sequential combination therapy with immunomodulators (e.g. peg-interferon) and NUC in virally-suppressed patients with chronic hepatitis B (CHB) can improve functional cure (HBsAg loss), as compared to NUC continuous monotherapy. Moreover, several strategies can be used to predict functional cure or identify patients likely to benefit from the sequential treatment with immunomodulators (e.g. peg-interferon), including baseline-guided therapy using pretreatment HBsAg level, response-guided therapy using early decline in HBsAg level, and HBVcore crab model using end-of-therapy HBsAb level and HBcAg level. We further have conducted two multicenter real-world studies—COST study and OCEAN study in China, aiming to investigate the efficacy and long-term outcome of sequential peg-interferon treatment in patients undergoing long-term NUC treatment who had HBV DNA undetectable and HBsAg level <3000IU/mL. The interim analysis of COST study demonstrated consistent results of the RCT studies. We are currently conducting a nationwide questionnaire survey on the application of functional cure strategies for patients with CHB.

MAFLD 1. Asian MAFLD: Clinical Features

MAFLD1-1

MAFLD in Patients living with HIV; PLWH

Dr. Sombat Treeprasertsuk
Department of Internal Medicine, Faculty of Medicine, Chulalongkorn University Thailand

Metabolic syndrome and metabolic dysfunction-associated fatty liver disease (MAFLD) are emerging problems and play important role in the higher morbidities and mortality in patients living with HIV (PLWH). The high MAFLD burden among PLWH is one of a major concern issue according to the novel MAFLD criteria and it needs to identify those patients at risk for chronic liver disease. Generally, the prevalence of MAFLD varies from 10-36% depended on the criteria of diagnosis and investigating tools1-5. Most of them are lean MAFLD with younger age in comparison to those MAFLD with diabetes or obesity. Current antiretroviral treatments for example tenofovir alafenamide fumarate (TAF) and particularly its combination with integrase inhibitors (INSTIs) appear to have the significant consequences on metabolic dysfunction by increasing insulin resistance6, 7. In addition, an unhealthy lifestyle, with a high calories dietary intake especially processed foods, high carbohydrates, saturated fatty acids, high fructose added beverages, as well as less physical inactivity, are key triggers for the progression of fatty liver to steatohepatitis, and
advanced liver fibrosis. Finally, we review the current recommendations of treatment in this special population at risk of MAFLD.

MAFLD1-2

How to follow up of patient with act Metabolic dysfunction-associated fatty liver disease (MAFLD)

Dr. Hong Soo Kim

Soon Chun Hyang University Hospital, Internal medicine Korea

Metabolic dysfunction-associated fatty liver disease (MAFLD) is the most common cause of chronic liver disease worldwide. MAFLD includes a wide spectrum of liver injury including simple steatosis and non-alcoholic steatohepatitis (NASH) that may lead to serious complications such as liver cirrhosis and liver cancer. The identification of Nonalcoholic steatohepatitis (NASH) or NAFLD but there is no accepted consensus on the optimal strategy for monitoring patients with NAFLD and their response to treatment.

According to The Asian Pacific Association for the Study of the Liver clinical practice guidelines for the diagnosis and management of metabolic associated fatty liver disease, patients with NAFLD may need a FibroScan yearly or once every three years. The frequency is dependent on your previous FibroScan results. It is important to distinguish mild (F1-F2) from advanced or severe (F3-F4) fibrosis, as patients with severe fibrosis have a greater risk of complications and need to undergo screening for hepatocellular carcinoma with NAFLD.

MAFLD 1. Asian MAFLD: Clinical Features

MAFLD1-4

Metabolic dysfunction-associated fatty liver disease: clinical features and implications

Dr. Wah Kheong Chan

Division of Gastroenterology and Hepatology, Department of Medicine, Faculty of Medicine, University of Malaya Malaysia

In 2020, the term metabolic dysfunction-associated fatty liver disease (MAFLD) was introduced. This was followed by the term metabolic dysfunction-associated steatotic liver disease (MASLD) in June 2023, which effectively retired the old term non-alcoholic fatty liver disease (NAFLD). While both of the new terms are a clear step forward, there are nuances between them that deserve considerations. The criteria to define metabolic dysfunction for MASLD is present in a large proportion of the general population, even among those without hepatic steatosis. Among those with normal body weight, many would be considered as having metabolic dysfunction based on the criteria, although only a small proportion actually have insulin resistance. These suggest that the criteria to define metabolic dysfunction for MASLD may be too relaxed. Furthermore, patients diagnosed with MAFLD based on presence of type 2 diabetes have been shown to have more severe liver fibrosis and greater risk of cardiovascular, cancer and all-cause mortality compared with patients with MAFLD who are diagnosed based on the other two criteria. This is an important consideration in our strategy to tackle the disease of interest. Last but not least, the introduction of a new entity called MASLD and increased alcohol intake (MetALD) encroaches into the field of alcohol-related liver disease and may embroil the disease of interest with unresolved issues surrounding alcohol-related liver disease. Differences aside, the adoption of either term is a clear recognition that the disease of interest is part of the bigger problem related to excess adiposity, insulin resistance and low-grade meta-inflammation. A paradigm shift is needed, where primary prevention should be the prevention of the onset of metabolic dysfunction instead of the prevention of cardiovascular disease or advanced chronic liver disease. There must be an increasing focus on lifestyle habits for promoting and preserving metabolic health during the entire life course at the individual level and beyond.

MAFLD 2. Asian MAFLD: Basic Understanding (Molecular Pathogenesis)

MAFLD2-1

Metabolic Dysfunction-Associated Liver Cancer

Dr. Shinji Tanaka

Department of Molecular Oncology, Tokyo Medical and Dental University Japan

Metabolic dysfunction caused by abnormalities in hepatic lipid metabolism is associated with an increased risk of developing liver cancer. The molecular mechanisms underlying the progression of
MASLD/NAFLD-associated liver cancer (MALC) are not fully understood. Animal models are extensively used for examining the molecular events under the conditions that mimic human disease. Several mouse models for liver cancer associated with metabolic disease have been established by using specific diets, chemotoxic agents, genetic engineering, or combinations thereof. Mice fed methionine- and choline-deficient diets are conventional models of nonalcoholic steatohepatitis, but they undergo weight loss. Although high-fat diets (HFDs) promote hepatic lipid accumulation, long-term exposure is required for tumor development. Streptozotocin, a compound selectively eliminating $\beta$ cells in the pancreas and resulting in type 1 diabetes, in combination with HFDs induces steatohepatitis and liver cancer without overweight or insulin resistance. Pten conditional knockout (KO) mice on HFDs also recapitulate MALC but not metabolic syndrome. Several congenital mutations are implicated in regulation of food intake and body weight in the hypothalamic nuclei, and these genetic mutations are the most common known monogenic causes of obesity in human. As reported in the previous studies, this regulator-KO mice exhibit obesity, insulin resistance, and dyslipidemia, and they develop steatohepatitis, liver fibrosis, and then well-differentiated liver cancer, suggesting this mouse model may be the best fit for reproducing the features of MALC. Cross-species comparison of gene expression signatures provides a powerful approach to evaluating the biological similarity between human patients and mouse models and to elucidating the molecular system in the common phenotype. Although there have been several comparative studies on human and mouse metabolic liver disease, the cross-species subtyping of liver cancer is focused in our studies. Here, we performed integrative transcriptome analysis of liver cancer resected from human patients and metabolic dysfunction-associated mice, and identified a subtype of liver cancer closely associated with metabolic syndrome, which was characterized by overexpression of several specific genes associated with metabolic dysfunction. We investigated the clinical significance of these metabolic molecules as a specific biomarker for this subtype and the correlation between the expression and metabolic dysfunction in our laboratory. Targeting these pathways may be a useful therapeutic strategy for the subtype-specific liver cancer.

MAFD 2. Asian MAFLD: Basic Understanding (Molecular Pathogenesis)

**MAFD2-2**

**Roles of SGLT2 Inhibitor in MAFLD-related HCC**

Dr. Takumi Kawaguchi

Department of Molecular Oncology, Tokyo Medical and Dental University Japan

MAFLD is becoming a leading cause of hepatocellular carcinoma (HCC) in the Asian-Pacific region. In the Japanese clinical practice guidelines for NAFLD/NASH, sodium-glucose co-transporter 2 inhibitor (SGLT2i) is recommended for patients with NAFLD and diabetes mellitus. However, the effects of SGLT2i on HCC remain unclear. First, we examined the expression of SGLT2 in human HCC cell lines and found that SGLT2 occurred and localized on mitochondria in Hep3B and Huh7 cells. Furthermore, SGLT2i significantly suppressed the proliferation of these HCC cell lines. To investigate the pathogenesis, we employed multi-omics analysis of metabolomics and absolute quantification proteomics (iMPAQT). This multi-omics analysis revealed that SGLT2i mainly altered the following metabolisms; 1) oxidative phosphorylation metabolism, 2) fatty acid metabolism, and 3) purine and pyrimidine metabolism. Moreover, SGLT2i altered the phosphorylation of AMP-activated protein kinase (AMPK) and acetyl-CoA carboxylase (ACC), which are sensors of intracellular ATP levels and regulators for beta-oxidation in mitochondria. Thus, We found that SGLT2i may suppress the proliferation of HCC cell lines via the regulation of electron transport systems, beta-oxidation, and nucleic acid synthesis.

HCC is known to release various chemokines/cytokines to modulate the tumor microenvironment and regulate the proliferation and invasion of HCC cells. Next, we investigated the direct effects of SGLT2i on tumor-releasing chemokines/cytokines in human HCC cell lines. Hep3B and Huh7 cells were treated with SGLT2i or a control vehicle for 24 h. Then, the culture media were collected and subjected to 48-plex panel (Bio-Plex Pro, Bio-Rad Laboratories, Inc., Hercules, CA). We first demonstrated that SGLT2i directly downregulated the three tumor-releasing chemokines such as C-X-C motif chemokine ligand (CXCL) 1, CXCL8, and CXCL10 in Hep3B and Huh7 cells. Based on the previous studies, these changes in chemokines may exert antitumor effects through alterations in tumor characters and tumor immunity.

In conclusion, SGLT2i directly suppressed the proliferation of HCC cells through alterations in mitochondrial oxidative phosphorylation metabolism, fatty acid metabolism, and purine and pyrimidine metabolism. SGLT2i also indirectly suppresses HCC by modulating the tumor microenvironment. I will introduce both direct and indirect molecular mechanisms for the effectiveness of SGLT2i on the suppression of HCC.

MAFD 2. Asian MAFLD: Basic Understanding (Molecular Pathogenesis)

**MAFD2-3**

The role of intestinal TM6SF2 in MAFLD

Dr. Vincent Wong

Department of Medicine and Therapeutics, The Chinese University of Hong Kong Hong Kong SAR, China

Metabolic dysfunction-associated steatohepatitis (MASH) is associated with the loss-of-function variant of Transmembrane 6 superfamily member 2 (TM6SF2). While TM6SF2 is primarily expressed in the liver and small intestine, the role of intestinal TM6SF2 dysfunction in MASH development remains unclear. In this study, we utilized systemic, liver-specific, and intestine-specific Tm6sf2 knockout mouse models to investigate the impact of TM6SF2 deficiency on MASH progression. We subjected the knockout mice and wildtype littermates to high-fat high-cholesterol (HFHC) or choline-deficient high-fat diet (CD-HFD) for 2 months to induce MASH. Additionally, fecal microbiota transplantation was performed in germ-free mice, and the therapeutic potential of microbiota modulation was examined by co-housing intestine-specific Tm6sf2 knockout mice with wildtype controls. We characterized the gut microbiota using shot-gun metagenomic sequencing and performed untargeted/targeted metabolomics using liquid chromatography-mass spectrometry. Our results showed that systemic Tm6sf2 knockout mice exhibited more severe steatohepatitis compared to liver-specific Tm6sf2 knockout mice, indicating the involvement of extra-hepatic TM6SF2 deficiency in MASH formation. Interestingly, intestine-specific Tm6sf2 knockout mice developed spontaneous MASH when fed a normal chow diet, which was further exacerbated by HFHC or CD-HFD supplementation. This MASH development in Tm6sf2ΔIEC mice was accompanied by impaired gut barrier integrity and dysbiosis of the gut microbiome. We observed an enrichment of the metabolite lysophosphatidic acid (LPA) in the stool, portal vein, and liver tissues of Tm6sf2ΔIEC mice, which in turn promoted hepatic lipid accumulation.
MAFLD 2. Asian MAFLD: Basic Understanding (Molecular Pathogenesis)

MAFLD-2

Therapeutic management of MAFLD/MASLD

Dr. Jian-Gao Fan

Department of Gastroenterology, Xinhua Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai Key Lab of Pediatric Gastroenterology and Nutrition, Shanghai China

The global incidence and prevalence of non-alcoholic fatty liver disease (NAFLD) and its severe form non-alcoholic steatohepatitis (NASH) have been steadily increasing over the past 2 decades, with a huge disease and economic burden. Recently, NAFLD and NASH have been renamed and redefined as metabolic dysfunction associated fatty liver disease (MAFLD)/metabolic dysfunction associated steatotic liver disease (MASLD) and metabolic dysfunction associated steatohepatitis (MASH), which result from an imbalance between metabolic and inflammatory stress (mainly as a consequence of adipose tissue dysfunction and insulin resistance) and the defence and repair mechanisms of the steatotic liver. Once MAFLD/MASLD progresses to end-stage of liver disease, treatment efficacy becomes limited and may require liver transplantation. Early detection and intervention are crucial. Lifestyle modification is consequently the cornerstone of its management. Timely consideration of bariatric surgeries should be given to patients meeting specific criteria. A multidisciplinary approach is warranted, starting from the concept that steatotic liver and steatohepatitis are at the centre of the cardiovascular-liver-metabolic syndrome. In some cases, pharmacological treatment can complement lifestyle modification. Several drugs used to treat the cardiometabolic co-morbidities have some potential efficacy in resolution of MASH and slowing down progression of liver fibrosis, and some drugs have demonstrated efficacy on histological endpoints that are likely to translate into long-term clinical benefits. Optimising the use of these drugs within their licenced indications for type 2 diabetes and obesity is thus paramount for patients with MAFLD/MASLD. Several MASH-specific drugs are on the horizon and are likely to enrich our therapeutic armamentarium in the near future, particularly in non-cirrhotic MAFLD/MASLD. Much work still needs to be done to understand the specific features of MAFLD/MASLD-related cirrhosis and develop efficacious treatments for this disease stage. Future research should focus on optimising lifestyle intervention strategies, improving adherence and success rates, exploring the role of new weight-loss medications, and identifying effective weight loss surgical methods for MASH patients with obesity. Combination therapies targeting multiple pathways and the integration of digital health interventions hold potential for enhancing the efficacy and safety of MAFLD/MASLD treatments.

MAFLD 3. Diagnosis of MAFLD

MAFLD3-1

Pathological Diagnosis of NASH, Fibrosis ad HCC

Dr. Michie Sakamoto

School of Medicine,International University of Health and Welfare Japan

Pathological diagnosis and interpretation of NASH is made based on the histopathological features of steatohepatitis, i.e. ‘steatosis’, ‘lobular inflammation’, hepatocyte ‘ballooning’, ‘Mallory-Denk bodies’ and ‘fibrosis’. However, there are many borderline cases that are difficult to evaluate. Pathologically, degeneration refers to a continuous and reversible change of morphology commonly seen in injured cells, mild, and moderate to severe pathological changes can be observed contemporaneously. This characteristic may also cause inconsistency in recognising and evaluating the presence of ballooning degeneration and Mallory-Denk bodies. The Japan Society of Hepatology published a clinical guidebook illustrating the typical histology of definitive hepatocyte ballooning and Mallory-Denk bodies. This guidebook may help to improve and unify the histological interpretations in diagnosing NASH. Despite these efforts, however, limitations of inter-observer variability will most likely remain. Therefore, quantitative assessment of these reversible and continuous degenerative changes is required. It is widely recognized that accurate staging of liver fibrosis is crucial to guide therapeutic decisions and to predict prognosis for patients with NASH. Digital image analysis (computational pathology) has emerged as a promising tool for quantitative assessment of fibrosis in chronic liver diseases. We measured area ratios of collagen and elastin fibers in Elastica van Gieson-stained biopsy tissues. The combined fiber area ratios correlated strongly with Brunt’s stage, but this relationship was non-linear with striking differences between stage 4 and stages 0–3. The highest tertile of the combined fiber area ratios was associated with fibrosis-4 index and serum type IV collagen 7s domain. Steatosis, is also a characteristic morphology of HCC. We previously reported that scirrhous HCC with steatosis has different clinicopathological significance than scirrhous HCC without steatosis. Furthermore, steatohepatitic HCC, which is characterized by a steatohepatitic morphology, has been reported as a subtype of HCC. We elucidated the features of macrovesicular steatosis (MaS) and microvesicular steatosis (MiS) in HCC. HCCs were classified as MaS-HCC, MiS-HCC, or conventional HCC (cHCC) according to the cutoff value of 30% MaS or MiS in tumor cells. MaS-HCC had less portal vein invasion, a higher proportion of HCC with intratumoral fibrosis, and a lower risk of recurrence than MiS-HCC or cHCC. Both MaS-HCC and MiS-HCC had lower incidences of hepatitis virus infection and higher levels of circulating lipids. These indicated that MaS-HCC and MiS-HCC were associated with metabolic dysfunction but exhibited different biological behaviors. In my lecture, these features of NASH/HCC will be discussed from pathological point of view.

MAFLD 3. Diagnosis of MAFLD

MAFLD3-3

Lean MAFLD

Dr. Mohammed Eslam

Storr liver center, Sydney University Australia

Excessive calorie consumption relative to expenditure, intake of unhealthy diets, and lack of physical activity are globally fuelling an increase in the prevalence of poor metabolic health, even in individuals...
of normal weight. Consequently, this trend entails increased risk of various metabolic disorders, including metabolic associated fatty liver disease (MAFLD), which affects up to a third of the global population. MAFLD burden has grown in parallel with rising rates of type 2 diabetes and obesity and increases the risk of end-stage liver disease, hepatocellular carcinoma, death, and liver transplantation, and has extrahepatic consequences including cardiometabolic disease and cancers. Although classically is associated with obesity, there is accumulating evidence that not all overweight or obese develop fatty liver disease. On the other hand, a considerable proportion of patients with MAFLD are lean, indicating the importance of metabolic health in disease pathogenesis regardless of body mass index. A complex and dynamic interaction between a multitude of factors, including genetic, epigenetic, dietary, and lifestyle factors, enterohepatic circulation, and gut microbiota is likely to shape individual metabolic health status.

The clinical profile, natural history and pathophysiology of lean patients with MAFLD is not well characterised. In this talk, I am going to provide the recent epidemiological data on this group of patients. The talk will illustrate the novel concept considering the overall metabolic health and metabolic adaptation as a framework to best explain the pathogenesis of MAFLD and its heterogeneity, both in lean and non-lean individuals. This framework provides a conceptual schema for interrogating the MAFLD phenotype in lean individuals that can translate to novel approaches for diagnosis and patient care. I will also touch briefly on the current management of lean patients with MAFLD.

MAFLD 3. Diagnosis of MAFLD

MAFLD3-5

Risk Stratification and Prediction of Hepatocellular Carcinoma in MAFLD

Dr. Takuma Nakatsuka
Department of Gastroenterology, The University of Tokyo Japan

Background: Metabolic dysfunction-associated fatty liver disease (MAFLD), which is strongly associated with systemic metabolic abnormalities, such as insulin resistance and glucose intolerance in the context of obesity, has become a leading cause of hepatocellular carcinoma (HCC) worldwide. Establishing an efficient surveillance strategy is urgently needed given the drastically increasing prevalence of MAFLD. However, optimal surveillance strategy remains unclear owing to the lack of evidence regarding risk stratification. Here we will show the utility of noninvasive tests for HCC risk stratification in patients with MAFLD.

Methods: Patients with MAFLD who underwent liver biopsy at our hospital were included. Liver stiffness measurement (LSM) using FibroScan was performed at the time of biopsy. FIB-4 index and Agile 3+ score (incorporating LSM, platelets, AST/ALT ratio, diabetes status, sex, age) were calculated. The performance of FIB-4 index, LSM, and Agile 3+ for diagnosing advanced fibrosis (AF: ≥F3) and predicting HCC was evaluated.

Results: Our cohort consisted of 300 patients with a median age of 55.0 years, median BMI of 27.8 kg/m2, median FIB-4 of 1.45, and median LSM of 8.7 kPa; 62.3% were male and 30.3% had diabetes mellitus. AF diagnostic performance (AUROC) was 0.82, 0.84, and 0.90 for FIB-4, LSM, and Agile 3+, respectively, with the Agile3+ being the best (DeLong test, P=0.001). During a mean observation period of 38.0 months after liver biopsy, 7 patients developed HCC. Compared to non-HCC cases, HCC-developed cases had significantly higher age at biopsy (54 vs 63 years, P=0.03), diabetes complication rate (29% vs 71%), FIB-4 (1.44 vs 2.49, P=0.03) LSM (8.7 vs 20.0 kPa, P<0.01), and Agile 3+ (0.79 vs 0.98, P=0.01). The c-index for predictive ability of HCC were 0.78, 0.80, and 0.85, for FIB-4, LSM, and Agile 3+, respectively. LSM ≥10 kPa, recommended cutoff value of cACLAD suspicion, could identify patients at high risk with an annual HCC incidence of 1.6%/PY, compared to 0.2%/PY in those with LSM <10 kPa (log-rank test, P=0.02). Furthermore, Agile 3+ >0.68, recommended cutoff value for AF rule-in, could identify patients with at high risk with an annual HCC incidence of 1.2%/PY, compared to 0.0%/PY in those with Agile3+ ≤0.68 (log-rank test, P=0.045).

Conclusion: LSM and Agile 3+ allow efficient risk stratification of HCC in patients with MAFLD. Their utilization would optimize personalized HCC surveillance strategy in MAFLD. Further studies are warranted to validate the utility of these tests in diverse MAFLD populations.

MAFLD 4. Clinical Management of MAFLD (Lifestyle Change Nutrition and Need of Medications)

MAFLD4-2

Cancer Prevention in patients with chronic HCV Infections

Dr. Ming-Lung Yu
National Sun Y et-sen University and Kaohsiung Medical University Taiwan

Hepatitis C virus (HCV) infections are a significant global health concern, contributing substantially to hepatocellular carcinoma (HCC), the sixth most prevalent cancer and fourth-leading cause of cancer-related deaths worldwide. The progression from chronic HCV infection to HCC spans 20 to 40 years, influenced by factors such as age at infection, viral genotype and loads, alcohol consumption, comorbidities (diabetes and obesity), HIV coinfection, gender, liver fibrosis, and host genetics.

While primary prevention through vaccination is ideal, there is currently no HCV vaccine. Consequently, HCC prevention focuses on effective antiviral therapy as secondary prevention for de novo HCV-related HCC and tertiary prevention for HCC recurrence after curative therapy. Achieving sustained virological response (SVR) with interferon (IFN)-based or directly-acting antiviral (DAA) agents significantly reduces HCC incidence, liver-related mortality, and HCC recurrence post-curtative therapy.

Despite SVR, the risk of HCC persists, with preexisting liver cirrhosis and age recognized as crucial risk factors. Understanding pathogenetic mechanisms and identifying risk surrogate biomarkers can enhance follow-up strategies post-HCV eradication. HCV infection induces epigenetic changes, including H3K27ac, associated with increased oncogene expression and decreased tumor suppression genes, persisting after SVR.

Several factors contribute to a higher post-SVR HCC risk, including advanced age, liver cirrhosis, diabetes, alcohol consumption, elevated baseline AFP (≥ 10 ng/mL), and specific genetic variations (MICA, PNPLA3, MBOAT7, TM6SF2, and GCKR). Notably, aspirin, metformin, and statin use have shown promising chemo-preventive effects, reducing HCC risk in large cohort studies among HCV-cured patients.

MAFLD 4. Clinical Management of MAFLD (Lifestyle Change Nutrition and Need of Medications)

MAFLD4-3

NAFLD/NASH and sarcopenia - usefulness of nutritional and exercise therapy -

Dr. Masahito Shimizu
Department of Gastroenterology, Gifu University Graduate School of Medicine Japan
Sarcopenia is associated with poor prognosis and impaired quality of life in patients with chronic liver disease. Nonalcoholic fatty liver disease/nonalcoholic steatohepatitis (NAFLD/NASH) and its underlying obesity and diabetes are closely related to the development and progression of sarcopenia. Sarcopenia is also a risk factor for NAFLD/NASH and liver fibrosis. Thus, NAFLD/NASH and sarcopenia adversely affect each other and impair hepatic and skeletal muscle function. Particularly, increased ammonia and decreased branched-chain amino acids are closely associated with these pathologies. In the treatment of NAFLD/NASH complicated by sarcopenia, nutritional and exercise therapy that simultaneously improves liver and skeletal muscle function, i.e., “liver rehabilitation”, is important. Weight reduction with diet and exercise therapy improves liver function and liver histology in NAFLD/NASH. For NAFLD/NASH patients with obesity, a low-calorie diet that limits carbohydrates and fats should be taught to optimize energy intake. On the other hand, weight loss due to inappropriate nutritional therapy, such as excessive protein restriction, may contribute to increased skeletal muscle catabolism and sarcopenia. Combined diet and exercise can further improve hepatic function and liver steatosis, but these conditions in patients with NAFLD may be improved even when only exercise therapy is implemented without nutritional therapy. With regard to exercise intensity, moderate and higher levels are more useful, and when comparing aerobic and resistance exercise, resistance exercise similarly improves hepatic steatosis in NAFLD patients, even though energy expenditure is lower than that of aerobic exercise. Resistance exercise is also useful in the prevention of sarcopenia because it effectively improves muscle strength and muscle mass. BCAA supplementation improves the prognosis of cirrhotic patients with sarcopenia. In these patients, the combination of BCAA preparations and exercise therapy is also useful in the treatment of sarcopenia. On the other hand, abnormal BCAA metabolism and over-intake are associated with type 2 diabetes, insulin resistance, and obesity, and are thought to promote hepatic fat accumulation and the development and progression of NAFLD/NASH. In cirrhosis resulting from NASH, the progression of fibrosis and the dynamics of amino acids, including BCAA, should be evaluated and BCAA replacement therapy should be considered. In conclusion, it is critical to develop safe and appropriate liver rehabilitation to improve the prognosis and quality of life of NAFLD/NASH patients with sarcopenia.

MAFLD 5. The Prognostic Event for MAFLD: CVD or Extrahepatic Cancers?

Treatment strategies of MASLD with a view to suppression of cardiovascular diseases and liver-related events

Dr. Norio Akuta
Department of Hepatology, Toranomon Hospital Japan

AASLD indicated that the most common cause of death in patients with MASLD is related to cardiovascular diseases (CVDs). Liver-related mortality was reported to be the second or third cause of death, and cancer-related mortality was among top three causes of death. In Asia, the incidence rates of these events still remain unclear. We retrospectively investigated the incidence of three complications (CVDs, malignancy except for liver cancer, and liver-related events) in 550 Japanese patients with biopsy-proven MASLD for median follow-up of 6.0 years. The yearly incidence rates of CVDs, malignancies, and liver-related events were found to be 1.04%, 0.83%, and 0.30%, respectively. Especially, in malignancy except for liver cancer, the incidence rates of colon cancer were 25.0%. The impacts of diet and exercise, and diabetes therapeutics with high evidence levels for suppression of CVDs should be evaluated in patients with MASLD. Regarding diet and exercise treatment, the subjects of retrospective cohort study were 203 Japanese patients with SLD diagnosed by abdominal ultrasonography. All of them were introduced the personalized diet and exercise treatment. A diet of 25 to 30 kcal/kg multiplied by ideal body weight daily and aerobic and resistance exercise (exercise intensity of 4 to 5 metabolic equivalents daily, respectively) were performed for 6 days. Treatment efficacy was evaluated in terms of the rate of decrease of liver function tests, glycolipid metabolism markers, physical findings, image findings, and CVD risk score (Suita score) at 6 months compared to baseline, and these parameters improved significantly. Regarding diabetes therapeutics, histological impacts at 5 years after the start of SGLT2 inhibitors were investigated retrospectively in 6 Japanese patients with MASLD and T2DM, and liver biopsies were obtained at the points of pretreatment, 3 years, and 5 years after the start of treatment. The primary outcome was liver histopathological changes at 5 years (defined as decrease in MASLD activity score of one point or more without worsening in fibrosis stage, compared to the pretreatment). 2 patients were performed the additional treatment of GLP-1 receptor agonist after the point of 3 years, and evaluated as histological worsening. Histological improvement, no change, and worsening were 50, 17, and 33% at 5 years, respectively. None developed CVDs events. In conclusion, the most common event in Japanese patients with MASLD was CVDs. Personalized medicine with diet and exercise, and diabetes therapeutics are expected to improve the pathology of MASLD, including the suppression of CVDs and liver-related events.

MAFLD 5. The Prognostic Event for MAFLD: CVD or Extrahepatic Cancers?

Prognostic event for MAFLD: CVD or Extrahepatic cancers

Dr. Yock Young Dan
Dept of Medicine. National University of Singapore Singapore

The diagnosis of Metabolic Associated Fatty Liver Disease (MAFLD) is based on the presence of hepatic steatosis associated with metabolic conditions such as type 2 diabetes mellitus (T2DM), obesity or metabolic dysregulation. The underlying metabolic disequilibrium, potentially manifesting as diabetes mellitus, hypertension, and hyperlipidaemia, is the same process that drives vascular atherosclerosis and increases the risk of carcinogenesis in multiple organs of the body. Hence it is no surprise that major adverse cardiovascular events (MACE) and extraintestinal cancers are the 2 commonest complications and causes of mortality in patients with MAFLD, constituting higher risks compared to liver complications such as cirrhosis and liver cancer.

We will review the risks for non-hepatic metabolic complications in patients at different stages of MAFLD and also the evidence for non-invasive tests (NIT) that can predict these life-threatening complications. Active management such as surveillance and aggressive management will be discussed.

MAFLD 5. The Prognostic Event for MAFLD: CVD or Extrahepatic Cancers?

The Prognostic Event for MAFLD: CVD or Extrahepatic Cancers?

Dr. Rakhi Maiwall
The metabolic dysfunction associated fatty liver disease (MAFLD) is a systemic disease that affects various extrahepatic organs. The prevalence varies from 30-40% and increases to 70% in patients who also have diabetes. Recent evidence has suggested an increase in the risk of chronic kidney disease as almost two-fold which is independent of the other cardiorenal risk factors. Apart from these, MAFLD is also associated with extrahepatic chronic complications. A very close association of MAFLD with diabetes, insulin resistance and obesity also confer a higher risk of hepatocellular carcinoma (HCC) including other extrahepatic malignancies. Mechanisms such as insulin resistance, metabolic stress causing disruption of the regulatory pathways for instance, nuclear factor-kappa B (NF-κB), phosphatase and tensin homolog (PTEN), and microRNAs have been observed to be associated with the development of HCC. The role of lipopolysaccharide-mediated signalling of the toll-like receptor 4 (TLR-4) which further perpetuates the hepatic inflammation and gut dysbiosis causing disrupted metabolism of bile acids has also been causally linked to the development malignancies in patients with MAFLD. The microbiota cause conversion of primary to secondary bile acids such as deoxycholic acid. These secondary bile acids are hepatotoxic and cause worsening of inflammo-fibrosis in MAFLD patients. Dietary intake of high fat and fructose intakes along with genetic factors (e.g., PNPLA3 polymorphisms) have shown to cause progression of the disease increasing the hepatic lipid accumulation. This perpetuates hepatic fibrosis. Accumulation of fat at ectopic locations and adipose tissue dysfunction have also been implicated in the development of MAFLD. Secretion of various hepatokines such as retinol-binding protein-4, fetuin-A, fibroblast-growth factor 21 and inflammatory cytokines, tumor-necrosis-factor alpha, C-reactive protein and interleukin-6 cause hepatic gluconeogenesis, glycogen synthesis and insulin resistance which together drives complications in these patients.

HCV 1. DAA Treatment for CH-C in Asia Pacific Region

**HCV1-I**

**Remaining issues in post-SVR era**

**Dr. Tetsuya Hosaka**

Department of hepatology, Toranomon Hospital Japan

Current direct-acting antiviral agents (DAAs) regimens can achieve sustained viral response (SVR) of over 97% in patients with chronic hepatitis C infection (CHC). Therefore, we are less likely to struggle with antiviral treatment for CHC. Several reports showed the eradication of HCV infection by DAAs therapy reduce the risk of HCC development. However, there are some patients who develop hepatocellular carcinoma (HCC) after SVR. Older age and advanced fibrosis are known risk factors of HCC after SVR. It is important to evaluate other risk factors of HCC. Then, we are going to focus on some metabolic factors and their association with HCC incidences after SVR among patients treated with DAAs or interferon (IFN)-based regimens in this lecture.

HCV 1. DAA Treatment for CH-C in Asia Pacific Region

**HCV1-4**

**Management of hepatitis C virus infection in Japan**

**Dr. Taro Yamasita**

Department of Gastroenterology Kanazawa University School of Medicine Japan

Globally, about 58 million people are estimated to have chronic Hepatitis C virus (HCV) infection, and most affected areas are considered Eastern Mediterranean, Europe, Western Pacific, Africa, regions of Americas, and Southeast Asia. HCV infection has been the most common etiology of liver cirrhosis and hepatocellular carcinoma in Japan. Major genotype of HCV has been genotype 1b, which is resistant to interferon-based therapies, following 2a and 2b in Japan. Accordingly, sustained virological response (SVR) rates were less than 50% before direct-acting antivirals (DAAs) developed and became available in 2014 in Japan. Currently, pan genotype DAAs glecaprevir/pibrentasvir and sofosbuvir/velpatasvir regimens are recommended for the treatment of HCV by the Japan Society of Hepatology, with attention to the status of renal function, presence of decompensated cirrhosis, and viral mutations including p32 deletion. SVR rates of these DAA regimens exceed 95%, and now almost all HCV infection can be successfully eradicated. However, because HCV infection is generally asymptomatic until the development of liver cirrhosis and hepatocellular carcinoma, most of patients are unaware of their HCV infection without screening tests. Furthermore, although most of HCV infected patients could relatively easily reach HCV testing and receive DAAs in urban areas, numbers of HCV infected patients are still considered undiagnosed and therefore remained untreated especially in rural areas in Japan. We are currently making an effort to provide the opportunity to receive the diagnosis and treatment of HCV infection in these people by utilizing information and communication technology.
patients with sustained virological response should undergo surveillance for HCC every 6 months by means of imaging and serum tumor markers.

HCV 2. Treatment with Direct Acting Antivirals (DAAs) for Cirrhotic Patients with or Without HCC

Risk factors of treatment failure of DAAs in chronic hepatitis C

Dr. Takeji Umemura
Department of Medicine, Division of Gastroenterology and Hepatology, Shinshu University School of Medicine Japan

In Japan, where the majority of patients are infected with Genotype 1 and 2, DAA treatment for chronic hepatitis C and compensated cirrhosis achieves SVR in nearly 100% of patients. In this study, we investigated the following two risk factors for the few cases of treatment failure among patients treated with DAA at Shinshu University Hospital and its affiliated hospitals in Japan: 1) DAA treatment for patients who had previously developed HCC and had been relapse-free for six months after radical treatment of HCC, and 2) serum chemokine levels measured before DAA treatment. 1) Of the 838 DAA-treated patients, 9.4% had prior HCC, and low pretreatment platelet counts and high AFP levels, advanced fibrosis (M2BPGi), and prior HCC were associated with treatment resistance, leaving prior HCC as the only risk factor in the multivariate analysis. 2) Nine chemokines were measured, and treatment resistance (56.3%; 9 of 16) was significantly observed in the group with low MIP-1β and high RANTES before treatment. Future issues are to improve the prognosis of patients with uncompensated cirrhosis by DAA treatment and the indication of DAA treatment in patients with HCC.

Morphological changes in esophageal varices in cirrhotic patients who achieved sustained virological response by direct-acting antivirals

Dr. Masanori Atsukawa
Division of Gastroenterology and Hepatology, Nippon Medical School Japan

Recently, DAAs have markedly improved treatment outcomes and have been approved for patients with liver cirrhosis including decompensated cirrhosis related with chronic HCV infection, which is frequently complicated by esophageal varices. Previously, some studies reported that achievement of SVR with DAAs decreased portal pressure to some extent. Recent studies reported post-SVR changes in the morphology of esophagogastric varices in patients with compensated cirrhosis. However, post-SVR esophageal variceal changes in patients with decompensated cirrhosis remain unclear. Therefore, this multicenter retrospective study aimed to clarify the morphological changes in esophageal varices after achieving SVR with DAAs treatment at 26 participating institutions in Japan. Among them, 243 patients underwent esophagogastroduodenoscopy before DAAs treatment and after achieving SVR. Our study included 125 males and 118 females with compensated or decompensated cirrhosis with a median age of 68 (range, 44–91) years. Esophageal varices before DAAs were classified into no varix in 155, F1 in 59, F2 in 25 and F3 in 4 patients. The improvement, unchanged, and aggravation rates of esophageal varices after SVR were 11.9%, 73.3%, and 14.8%, respectively. Low platelet count was extracted as an independent factor associated with esophageal varices aggravation. Of the 155 patients without esophageal varices before DAAs treatment, 17 developed de novo post-SVR esophageal varices. High ALBI score was extracted as an independent factor associated with de novo post-SVR esophageal varices. The cumulative incidences of de novo esophageal varices were 0%, 6.7%, and 17.7% at 1, 3, and 5 years, respectively. In conclusions, patients with cirrhosis can experience esophageal varices aggravation despite achieving SVR. In particular, patients with low platelet count and high ALBI score such as decompensated cirrhosis had a high likelihood of developing esophageal varices aggravation and de novo esophageal varices, respectively, even for long periods after achieving SVR.

HCV 3. Prognosis Portal Hypertension HCC in Post SVR CH-C/cirrhosis

Evaluation of the usefulness of liver stiffness in cancer development after DAA treatment for chronic liver disease type C

Dr. Koichi Takaguchi
Department of Hepatology Kagawa Prefectural Central Hospital Japan

Purpose: DAA treatment eliminated Hepatitis C Virus (HCV) in most cases of type C chronic liver disease. However, some cases of SVR are also found to develop cancer. Here we report on whether subsequent carcinogenesis can be predicted in cases in which liver stiffness was measured at the start of treatment.

Method: Of the 751 patients who received DAA at our hospital by March 2023, 234 patients (115 men, 119 women, Average age: 64.6 years, Genotype 1: 144 cases, Genotype 2: 88 cases, Genotype 3: 1 case, Unknown: 1 case) with type C chronic liver disease were measured Liver stiffness(LS) before DAA treatment.

Results: The average observation period after completion of administration was 38.1 months. During this period, 7 cases developed cancer. The 5-year cancer incidence rates for all cases was 3.8%. The five-year cancer incidence rate for LS, platelets(PLT), Alb, AFP, ALBI score, hyaluronic acid, M2BPGi, FIB4index, and FAST before administration was 1.0% for LS less than 14.8, 16.8% for 14.8 or more, and 9.0% for PLT less than 134,000/μL, 134,000/μL or more: 2.1%, AFP less than 7ng/mL: 2.5%, 7ng/mL or more: 7.4%, Hyaluronic acid less than 298ng/mL: 1.4%, 298ng/mL or more: 13.4%, M2BPGi less than 1.92: 1.9%, 1.92 or more: 6.2%, FIB4index less than 7ng/mL: 2.5%, 7ng/mL or more: 7.4%, Hyaluronic acid less than 298ng/mL: 1.4%, 298ng/mL or more: 13.4%, M2BPGi less than 1.92: 1.9%, 1.92 or more: 6.2%, FIB4index less than 3.20: 1.2%, 3.20 or more: 7.4%, ALBI score, hyaluronic acid, M2BPGi, FIB4index, and FAST before administration were found to be predictive factors for subsequent carcinogenesis in patients with DAA treated chronic HCV infection.

Conclusion: The liver stiffness measured before administration and the liver stiffness after administration were found to be predictive factors for subsequent carcinogenesis in patients with DAA treated chronic HCV infection.
Dr. Si Hyun Bae
Division of Hepatology, Department of Internal Medicine, Eunpyeong St. Mary’s Hospital, The Catholic University of Korea, The Catholic University Liver Research Center Korea

Globally, an estimated 58 million people have chronic hepatitis C virus (HCV) infection, with about 1.5 million new infections occurring per year. In 2019, an estimated 290,000 deaths were attributed to hepatitis C-related complications. The primary treatment goal for hepatitis C is the eradication of the HCV to prevent complications such as fibrosis, cirrhosis, portal hypertension, hepatocellular carcinoma (HCC), and extrahepatic manifestations, ultimately leading to a reduction in mortality. The clinical endpoint of antiviral therapy is achieving a sustained virologic response (SVR) at 12 weeks post-treatment, where no detectable HCV RNA is found in the bloodstream. Recent advancements in interferon (IFN)-free direct-acting agents (DAAs) have dramatically improved SVR rates. Achieving SVR leads to improvements in fibrosis and portal hypertension. It is known that reaching SVR is associated with the regression of liver stiffness, which is linked to a decrease in liver-related complications and mortality. According to Lens et al.’s research, HCV-related cirrhotic patients who achieved SVR showed progressive reductions in hepatic venous pressure gradient (HVPG), and those with high baseline HVPG were more likely to experience decompensation events. Achieving SVR significantly reduces the risk of hepatic decompensation. Meta-analyses show that SVR lowers this risk by 84% and 89% in the interferon and DAA eras, respectively. A Korean multicenter study found no significant difference in decompensation events between IFN-SVR and DAA-SVR patients. Achieving SVR also reduces the risk of developing HCC. SVR results in an approximately 70% reduction in the risk of HCC development, with this effect becoming evident within 3–6 months and increasing over time. Some studies suggest that there may be differences in HCC risk reduction between cirrhotic and non-cirrhotic patients after SVR. And various prediction models for post-SVR HCC risk have been reported. In conclusion, achieving SVR in hepatitis C patients is closely associated with favorable outcomes in terms of fibrosis regression, portal hypertension improvement, reduced HCC risk, and enhanced survival. However, it is important to note that certain high-risk groups may still require vigilant monitoring even after achieving SVR.

HCV 3. Prognosis Portal Hypertension HCC in Post SVR CH-C/cirrhosis

HC3-3

Influence of HVPG in predicting outcomes in liver disease

Dr. Ankur Jindal
Additional Professor, Department of Hepatology, Institute of Liver and Biliary Sciences India

Portal hypertension is a severe, almost unavoidable complication of chronic liver diseases and is responsible for the main clinical consequences of cirrhosis. Measurement of the hepatic venous pressure gradient (HVPG) is currently the best available method to evaluate the presence and severity of portal hypertension. Clinically significant portal hypertension is defined as an increase in HVPG to ≥10 mmHg; above this threshold, the complications of portal hypertension might begin to appear. Measurement of HVPG is increasingly used in clinical hepatology, and numerous studies have demonstrated that the parameter is a robust surrogate marker for hard clinical endpoints. The main clinical applications for HVPG include diagnosis, risk stratification, identification of patients with hepatocellular carcinoma who are candidates for liver resection, monitoring of the efficacy of medical treatment, and assessment of progression of portal hypertension. Patients who experience a reduction in HVPG of ≥20% or to <12 mmHg in response to drug therapy are defined as ‘responders’. Responders have a markedly decreased risk of bleeding (or rebleeding), ascites, and spontaneous bacterial peritonitis, which results in improved survival.

HCC Percutaneous Ablation for Liver Tumors

HCC1-2

Microwave Ablation for Hepatocellular Carcinoma

Dr. Shinichiro Nakamura
Japanese Red Cross Society Himeji Hospital Department of Internal Medicine Japan

Background and aim: The next-generation microwave ablation (MWA) has been developed as a new percutaneous thermal ablation therapy for hepatocellular carcinoma (HCC). Compared to radio-frequency ablation (RFA), MWA has the advantage of faster heating and less susceptibility to heat sink effects due to the higher temperature generated and can make predictable spherical ablation zones. We describe our MWA procedure and the clinical outcomes of patients with HCC.

Methods: We treat Child A or B patients with tumors less than 4 cm in diameter and three or fewer tumors without vascular invasion. MWA-antenna puncture was performed under ultrasound guidance. When the tumor was difficult to visualize using B-mode ultrasound, contrast-enhanced US (CEUS) or fusion imaging with CECT or GdEOB-DTPA enhanced MRI was used as a complementary method for MWA. If needed, artificial pleural effusion or ascites were prepared using a 5% glucose solution.

Results: Between September 2019 and September 2023, 564 consecutive patients with 802 HCCs (maximum tumor diameter ≤40 mm) were included. The median maximum tumor diameter was 13.0 (interquartile range, 10.0–18.0) mm. We use CEUS, pleural effusion, and artificial ascites during MWA in 326 (40.7%), 73 (9.1%), and 439 (54.7%) HCCs, respectively. The cumulative local tumor recurrence rates at 1, 2, and 3 years were 4.6%, 8.6%, and 9.8%, respectively. The cumulative local tumor recurrence rate differed significantly by tumor size group: ≤20 mm group (n=651), 20–30 mm group (n=132), and ≥30 mm group (n=19) (p=0.0001). In the multivariable analysis, tumor size (per 1 mm) (hazard ratio [HR], 1.07; 95% confidence interval [CI], 1.03–1.11; p=0.0002) and ablative margin (per 1 mm) (HR, 0.83; 95% CI, 0.74–0.93; p=0.0019) were significantly associated with local tumor recurrence. Complications after MWA were observed in 40 cases (5.0%), and the major cases were biloma, 10; portal vein thrombosis, 9; bile duct dilatation, 6; pleural effusion, 5. Only tumor size (per 1 mm) (odds ratio, 1.08; 95% CI, 1.04–1.13; p=0.0002) was significantly associated with complications. Tumors located at difficult-to-treat Child A and B patients were included. For optimal results, we used CEUS, pleural effusion, and artificial ascites during MWA. If needed, artificial pleural effusion or ascites were prepared using a 5% glucose solution.

Conclusion: MWA is a safe and effective local ablation therapy for HCC.
Strategic Optimization of Percutaneous Liver Ablation: A Comprehensive Approach

Dr. Hyunchul Rhim
Department of Radiology Samsung Medical Center, Sungkyunkwan University Korea

Percutaneous liver ablation is pivotal in modern liver cancer management, necessitating a tailored strategy for heightened effectiveness. This overview explores the imperative of strategic optimization, highlighting key components contributing to enhanced patient outcomes. Strategic optimization involves a personalized methodology that extends beyond conventional practices. Incorporating advanced technologies and tailored patient care, practitioners can boost precision and procedural efficacy. Individualized treatment plans, guided by advanced imaging, enable accurate tumor delineation, minimizing collateral damage to healthy tissues.

Economic considerations are pivotal in the strategic optimization framework. Evaluating the cost-effectiveness of ablation techniques ensures judicious resource allocation without compromising patient care—a crucial aspect in the era of value-based healthcare. Additionally, the overview emphasizes collaboration across medical disciplines. Integrating insights from radiology, oncology, and interventional medicine enriches research and facilitates the exchange of best practices.

In conclusion, strategic optimization in percutaneous liver ablation represents a paradigm shift. This overview outlines its key components, underlining its potential to redefine standards of care, improve outcomes, and shape the future of interventional oncology.

HCC Can Drug Therapy and Classical Local Treatment Coexist?
HCC2-3

TACE plus systemic therapy: How and Who

Dr. Stephen Lam Chan
Department of Clinical Oncology, Faculty of Medicine, The Chinese University of Hong Kong Hong Kong SAR, China

Conventionally, TACE is reserved for patients with intermediate disease of HCC while systemic therapy is indicated following TACE treatment or in the presence of advanced disease. However, this concept is being challenged by recent randomized data showing that the addition immunotherapy-based systemic therapy to TACE could improve outcomes. The lecture will review the latest efficacy and safety data on the combination. Patient selection for this treatment combination will also be discussed.

HCC Can Drug Therapy and Classical Local Treatment Coexist?
HCC2-4

Basis of combination therapy by radiofrequency thermal ablation and immune checkpoint blockade for unresectable hepatocellular carcinoma

Dr. Hidetoshi Nakagawa
Gastroenterology, Institute of Medical, Pharmaceutical and Health Sciences Kanazawa University Japan

Introduction: Despite significant advancements in cancer treatment since the establishment of immune checkpoint blockade, a considerable number of patients do not benefit from the latest immunotherapies, often due to insufficient tumor-infiltrating lymphocytes or limited antigen exposure. To address this, we propose leveraging the 'abscopal effect' through local ablation therapy before immunotherapy in patients with unresectable hepatocellular carcinoma.

Methods: We evaluated the antitumor effects of radiofrequency ablation (RFA) in BNL/ MC38 tumor-bearing mice. RFA was applied to one of two bilateral tumors, with the untreated tumor monitored to assess antitumor responses. To explore the underlying mechanisms, we examined the roles of different immune cell subsets using nude mice, clodronate liposomes, and CD4/CD8 depletion antibodies. We also initiated a clinical study, "Randomized Phase II study of preceding radiofrequency ablation to atezolizumab plus bevacizumab combination therapy for patients with unresectable hepatocellular carcinoma (jRCT10412000075)." This study involves treating selected hepatic lesions with RFA before administering atezolizumab and bevacizumab to patients with unresectable hepatocellular carcinoma. The study includes a safety confirmation cohort (n=6) and a randomized cohort (n=60), focusing on progression-free survival as the primary endpoint and overall survival, objective responses, tumor control rates, and immunological responses as secondary endpoints.

Results: Animal studies demonstrated that RFA enhanced antitumor effects in residual tumors. Experiments in nude mice with BNL tumors confirmed that this enhancement was T-cell mediated. Macrophage ablation with clodronate liposome did not affect tumor growth in wild-type BNL mice. Tests using CD4 or CD8 depletion antibodies showed that T cells were responsible for the enhanced antitumor effects in MC38-bearing mice. Preliminary results from the clinical study's safety cohort indicate the combination therapy's safety and feasibility. Over a median observation period of 885 days, the best responses included one partial response and five stable diseases, with a median progression-free survival of 175 days.

Conclusions: The combination therapy involving RFA and cancer immunotherapy, with the aim of eliciting abscopal effects, presents a promising avenue in cancer immunotherapy. Preliminary results from the clinical trials support the safety and feasibility of this combination approach, encouraging further investigation.

HCC Will Adjuvant Chemotherapy Post-Curative Treatment for Hepatocellular Carcinoma Be a Paradigm Shift?
HCC2-1

Will Adjuvant Chemotherapy Post-Curative Treatment for Hepatocellular Carcinoma Be a Paradigm Shift?

Dr. Masafumi Ikeda
Department of Hepatobiliary and Pancreatic Oncology at the National Cancer Center Hospital East Japan

According to the Barcelona Clinic Liver Cancer (BCLC) staging system, a single tumor or tumor size of ≤3 cm of hepatocellular carcinoma (HCC) are classified as early-stage, and liver resection, liver transplantation, or local ablative therapy is recommended. These treatments aim for complete cure, and systemic therapy was firstly developed as post-curative adjuvant therapy. Although no standard post-curative treatments have been established yet, the effectiveness of adjuvant atezolizumab plus bevacizumab (Atezo+Bev) therapy as compared to active surveillance (IMbrave050) was demonstrated in 2023. The primary endpoint of recurrence-free survival (RFS) demonstrated to be significantly better in Atezo+Bev than in active surveillance [12-month RFS: Atezo+Bev 79% vs. active surveillance 68%, hazard ratio 0.70 (95% confidence interval: 0.54-0.91, p=0.007)]. In the subgroup analysis of RFS, the benefits of Atezo+Bev were consistent across all subgroups. However, there was no difference in overall survival [hazard ratio 1.42 (95% confidence interval: 0.80-2.54)], and the Kaplan-Meier curves for RFS became close after 2 years, suggesting the suppressive effect for early recurrence and no suppressive effect after 2
years. As the follow-up period (median) is still short at 17.4 months, long-term follow-up results are warranted.

Currently, in the early-stage HCC, post-curative treatment of systemic therapies are underway as comparator of placebo: EMERALD-2 (NCT03847428) compared with durvalumab plus bevacizumab, CheckMate9XD (NCT03383458) compared with nivolumab, and KEYNOTE-937 (NCT03867084) compared with pembrolizumab. These phase III trials are focusing on combined therapy or monotherapy of immune checkpoint inhibitors. From these results, whether a single immune checkpoint inhibitor or a combination of an immune checkpoint inhibitor and a VEGF inhibitor is necessary for adjuvant therapy will be determined.

The next step toward adjuvant therapy in patients with hepatocellular carcinoma

Dr. Kaoru Tsuchiya
Department of Gastroenterology and Hepatology, Musashino Red Cross Hospital Japan

Adjuvant therapy for patients with hepatocellular carcinoma (HCC) after curative treatment, including resection and ablation, is still unestablished in clinical practice. There are some clinical studies that aim to prove prevention of HCC recurrence after curative treatment. The phase 3 clinical trial, atezolizumab plus bevacizumab versus active surveillance in patients with resected or ablated high-risk HCC (IMbrave050), already showed positive results. The recurrence-free survival (RFS) was significantly longer in the patients treated with atezolizumab plus bevacizumab compared to the patients with active surveillance. In this study, the majority (88%) of patients received resection, and 90% of the patients treated with resection had solitary tumors. Moreover, 82% of patients were recruited from Asia, and 62% had HBV infection. In Western countries and Japan, the percentage of HCC patients with HBV infection is about 10%, and the number of non-viral HCCs, including MASLD, has been increasing globally. Even though this study met the primary endpoint, the median duration of follow-up was only 17.4 months in the treatment group and 17.6 months in the active surveillance group. IMbrave050 trial was the first successful clinical study and the first step toward adjuvant therapy in HCC. However, there are many concerns about adjuvant settings. First, we have to identify the patients with high-risk populations of recurrence. In the IMbrave050 trial, only 7 patients in the treatment group and 3 patients in the active surveillance group had ≥ 3 tumours. Second, we should mention the etiologies of patients. Third, it is important to consider the toxicity of adjuvant therapy. In the IMbrave050 trial, grade 5 adverse events occurred in 6 patients (2 of which were treatment-related) in the treatment group and 1 patient in the active surveillance group. In real-world practice, several studies were performed by using transarterial chemoembolization (TACE) + portal vein chemotherapy (PVC) or internal radiotherapy (IRT) as adjuvant therapy after curative resection in HCC and showed positive results. Although atezolizumab plus bevacizumab has been recommended as first-line systemic therapy in most HCC guidelines, it should be evaluated by comparing other therapies as adjuvant therapy. The next step toward adjuvant therapy in HCC is to solve such clinical questions and establish the appropriate adjuvant therapy for each patient.
Liver-Resident Natural Killer Cells as Adjuvant Treatment for Hepatocellular Carcinoma Post-Liver Transplantation

Dr. Masahiro Ohira
Department of Gastroenterological and Transplant Surgery, Hiroshima University Japan

Effective prevention or treatment strategies for hepatocellular carcinoma (HCC) recurrence following liver transplantation (LT) are currently lacking. Standard immunosuppressive protocols post-LT tend to preserve innate immune components while suppressing adaptive cellular immunity. Central to the innate immune response, Natural Killer (NK) cells are pivotal in defending against neoplastic cells, making their enhancement a viable immunotherapeutic strategy against HCC post-LT. We suggest that the adoptive transfer of liver-resident NK cells, harvested from the donor liver graft perfusate, could induce an anti-tumor response without harming the recipient's healthy tissues. In our study, 99 patients who preoperatively met the Japan criteria were examined. Of these, 42 patients who postoperatively exceeded the Milan criteria demonstrated significantly lower recurrence-free survival rates compared to the 57 within the criteria (p=0.022). Remarkably, among patients beyond the Milan criteria, those treated with NK cell therapy (n=17) showed a marked improvement in recurrence-free survival rates. Following NK cell infusion, we observed a significant increase in NK cell cytotoxicity and the percentage of TRAIL+ NK cells in the patients’ peripheral blood (p<0.05). The administered donor NK cells were detectable in the peripheral blood up to one month post-infusion.

Our collaborative research with the University of Miami, initiated in 2009, has extended this approach to deceased donor LT (DDLT) recipients. This phase I trial encompassed 17 subjects with a median follow-up of 96 months, recording no adverse events related to the study. The high-dose NK cell group exhibited a significantly superior overall survival rate compared to the low-dose group (p=0.0064). Among the DDLT series for HCC, 53% of patients meeting the Milan criteria preoperatively had pathological findings exceeding the criteria postoperatively, yet none have experienced HCC recurrence to date. In conclusion, IL-2 stimulated NK cells from both living and deceased donor liver transplants have been safely administered, suggesting a promising adjuvant immune therapy for HCC patients post-LT. A multicenter phase II trial is now underway in Japan and the USA.

New FP therapy for long-term prognosis in patients with advanced hepatocellular carcinoma

Dr. Hiroaki Nagamatsu
Department of Gastroenterology, Juntendo University Japan

Introduction: In Japan, hepatic arterial infusion chemotherapy (HAIC) is recommended as an optional treatment in the 2021 guidelines. In 2021, New FP therapy (NFP) was reported to have a longer prognostic effect than sorafenib in advanced hepatocellular carcinoma with intrahepatic lesions.

Objectives: I will show the performance of NFP in this study at our hospital.

Subjects: We perform 2 courses using the temporary indwelling catheter system via the left brachial artery, and then we remove the temporary reservoir during hospitalization. We repeat this treatment 3 to 5 times with an interval of about 2 months. We aim for cancer free by performing conversion therapy when PR or CR is obtained by NFP. We performed NFP on 290 patients with advanced with vascular invasion.

Results: There is almost no deterioration liver function. A total of 200 patients (69%) responded to NFP therapy, of which 80 patients achieved cancer-free outcome. 32 patients became cancer-free outcomes with only NFP. We were able to add hepatic resection to 33 patients. Median OS (MST) after HAIC in all patients was 18 months. MST in patients who responded was 29 months, and in patients who achieved cancer-free outcome, it was extended to 67 months. The 5-year survival rate of all patients was 22%, and 67% for patients who got cancer-free outcome.

Conclusions: NFP has a high response rate and contributes to improve or maintain liver function by controlling PVTT. In response cases, long-term survival can be obtained by adding conversion therapy.

HCC Advancements in Radiation Therapy for Hepatocellular Carcinoma

HCC7-1

Carbon-ion radiotherapy for hepatocellular carcinoma

Dr. Masaru Wakatsuki

Department of Diagnostic Radiology and Radiation Oncology, QST Hospital, National Institute for Quantum Science and Technology Japan

Radical treatment options for bulky unresectable locally advanced hepatocellular carcinoma (HCC) are limited. Stereotactic Body Radio Therapy (SBRT) is becoming popular in many countries as an effective treatment option for relatively small hepatocellular carcinomas, there are problems in terms of its effects on the normal liver and its efficacy against large hepatocellular carcinomas. Carbon-ion radiotherapy (C-ion RT) has improved dose distribution properties owing to Bragg peak and less lateral scattering and enable to perform higher prescribed dose for HCC than that of photons. Take advantage of this feature, C-ion RT is becoming popular in Japan as a new curative treatment option. National Institute for Quantum Science and Technology (former the National Institute of Radiological Sciences) began treating patients with C-ion RT in 1994 and has treated approximately 1,000 cases of hepatocellular carcinoma to the present. Since April 2022. Its effectiveness with bulky hepatocellular carcinoma with vascular invasion, patients with low liver function, and patients with bulky hepatocellular carcinoma. In this presentation, I would like to show the results of treatment to date and introduce the challenges and future directions of C-ion RT for hepatocellular carcinoma.

HCC Advancements in Radiation Therapy for Hepatocellular Carcinoma

HCC7-2

The Role and Future of Stereotactic Body Radiotherapy for Hepatocellular Carcinoma

Dr. Yoshiko Doi

Department of Radiation Oncology, Hiroshima Prefectural Hospital Japan

With advancements in imaging diagnostics and radiation therapy techniques, the application of stereotactic body radiotherapy (SBRT), delivering high doses of radiation in a short time, has become more feasible. Numerous studies have reported the high therapeutic efficacy and safety of SBRT for hepatocellular carcinoma (HCC). A prospective, phase II multicenter study of SBRT in previously untreated solitary primary HCC (STRSPH study) was conducted in Japan and reported a 90% local control rate and a 3-year overall survival (OS) rate of 78%. This study included many elderly patients and patients with comorbidities for whom standard treatments (radiofrequency ablation (RFA) and surgical resection) were not applicable, but the high local control rate and low toxicity of SBRT are thought to have led to the good results.

On the other hand, in the global treatment algorithm for HCC, decisions are guided by the Grading of Recommendations Assessment, Development, and Evaluation (GRADE) system. Consequently, treatment options rich in evidence, such as liver resection, RFA, transarterial arterial chemoembolization, liver transplantation, and chemotherapy, are considered in the selection of HCC treatment. Unfortunately, among studies evaluating SBRT outcomes, none have presented high-quality clinical evidence assessable by the GRADE system. So, SBRT is absent from the treatment algorithm.

Nevertheless, studies have shown positive results not only in SBRT outcomes, but also in studies comparing outcomes with other treatment modalities in retrospective study. A meta-analysis of tumor outcomes for HCC treated with RFA or SBRT, utilizing meticulously selected studies, reported no significant difference in the OS rate between the two modalities (1- and 2-year OS rates were 91.8% and 77.7% after RFA, and 89.0% and 76.0% after SBRT, respectively). SBRT exhibits notably high local treatment efficacy, particularly acting as a breakthrough in challenging scenarios where RFA is difficult (such as lesions just below the diaphragm, on the liver surface, perivascular lesions, and conditions with a bleeding tendency, as well as cases with tumors not visible by ultrasonography) or in instances of recurrence post-TACE. This underscores its potential as a promising therapeutic approach contributing to overall prognosis improvement for HCC patients. It is imperative for radiation oncologists to communicate the heightened therapeutic efficacy and safety of SBRT to hepatologists and surgeons, making sustained efforts to broaden the applicability of SBRT implementation.

HCC Advancements in Radiation Therapy for Hepatocellular Carcinoma

HCC7-3

Experience in clinical trials combining immunotherapy and radiotherapy

Dr. Hee Chul Park

Department of Radiation Oncology, Samsung Medical Center, Sungkyunkwan University School of Medicine Korea

While systemic therapy is recommended for HCC patients with MVI by many academic guidelines, various liver-directed therapies such as surgical resection, transarterial chemoembolization with or without radiotherapy, and radioembolization have demonstrated significant outcomes. There may be an unmet need for improved treatment strategies integrating systemic and liver-directed therapy in patients with HCC and MVI.

External beam radiation therapy (EBRT) can be applied to patients with HCC in various situations, including those with symptomatic primary liver or metastatic lesions. Recent advances in the EBRT techniques, such as with stereotactic body radiotherapy (SBRT), proton beam therapy (PBT), and carbon ion radiotherapy, have enabled the delivery of higher radiation doses to achieve excellent local control. While systemic therapy is recommended for HCC patients with MVI by many academic guidelines, various liver-directed therapies such as surgical resection, transarterial chemoembolization with or without radiotherapy, and radioembolization have demonstrated significant outcomes. There may be an unmet need for improved treatment strategies integrating systemic and liver-directed therapy in patients with HCC and MVI.

be expected to exert a synergistic effect in cancer treatment. Radiation therapy can have immunostimulatory effects. Substantial preclinical studies have shown that radiotherapy may synergize with immunotherapy. Preliminary clinical studies have recently been reported. A phase 1 trial of SBRT combined with immunotherapy (nivolumab with or without ipilimumab) exhibited favorable outcomes, and the combination therapy of EBRT and atezolizumab/bevacizumab demonstrated acceptable safety.

Based on the CheckMate-040 trial, which showed promising clinical activity and a favorable safety profile, nivolumab, a PD-1 inhibitor, obtained accelerated approval from regulatory agencies worldwide, including South Korea, as a second-line treatment, and a global first-line nivolumab trial could be initiated. Nivolumab monotherapy demonstrated a durable response in some patients; however, the response rate still remained at 20%. EBRT has shown good local control in HCC and may potentiate immunotherapy through immunomodulatory effects; therefore, we conducted a phase 2 study evaluating the efficacy and safety of concurrent therapy with nivolumab and EBRT in patients with advanced HCC and MVI.

HCC Bridging Clinical and Basic Research

Establishment of Genome analysis center, From Genomic Analysis to Clinical Practice in Hepatocellular Carcinoma

Dr. Kenji Amemiya

Genome Analysis Center, Yamanashi Prefectural Central Hospital

Japan

In 2019, Comprehensive Genomic Profiling test became eligible for insurance coverage, marking the widespread adoption of cancer genomic medicine. Our institution established a Genomic Analysis Center in April 2013 and has been actively engaged in cancer genomic medicine.

Yamanashi Prefectural Central Hospital has accumulated cancer registration data since 2006, totaling 29,024 cases (including 1,163 with hepatocellular carcinoma, HCC), and has obtained genomic informed consent from 9,484 patients (including 313 with HCC). We developed an in-house panel targeting Significantly Mutated Genes for each cancer type. Using NGS platforms (Genexus, Proton, PGM), we performed sequencing on 15,213 samples (lung 2,758, biliary/pancreatic 1,839, gynecological 921, liver 906, stomach 572, urological 532, breast 304, and others), generating a total of 5.6 trillion bases. Additionally, we have published 112 peer-reviewed articles.

In HCC, registration using REDCap in the A-HOC (APASL Hepatology/Oncology Consortium) has reached 506 cases. Analysis using in-house HCC panels (72 SMGs: 59,016 amino acids) has been completed for 198 cases 355 nodules (solitary: 130 patients with 130 nodules, synchronous: 33 patients with 81 nodules, metachronous: 16 patients with 35 nodules, syn+meta: 19 patients with 75 nodules). Whole transcriptome data has been obtained for 300 of these samples. There are 689 cases of DAA (Direct-Acting Antiviral) treatment, and tumor marker data (AFP, AFP-L3, DCP) have also been collected for these cases. Considering these data, we aim to validate the clinical applications of HCC analysis from a multifaceted perspective, including ① post-DAA occurrence of HCC, ② dynamics of oncogenic driver in serially occurring HCC nodules ③ the correlation between tumor markers and clinical/genomic data.

NAFLD becomes a promoter of hepatocellular and cholangiocellular tumors in mice

Dr. Shin Maeda

Department of Gastroenterology, Yokohama City University Graduate School of Medicine

Japan

Background: It is epidemiologically clear that NAFLD, which is an increasing trend in recent years, accelerates hepatic inflammation, fibrosis and liver cancer development. In contrast, it is unclear whether NAFLD affects the cholangitis or development of another liver cancer, cholangiocellular carcinoma (CCC). The aim of this study is to investigate whether high fat diet promotes cholangitis and development of cholangiocellular tumors in mice.

Methods: We use liver-specific E-cadherin gene (Cdh1) knockout mice, Cdh1AI, which was generated by crossing Cdh1lox/lox mice with Albumin-Cre transgenic mice, with spontaneous inflammation in the portal areas and periductal onion skin-like fibrosis, which resembles primary sclerosing cholangitis (PSC). High fat diet or normal diet
was fed into the Cdh1∆Li mice for 7 months. In addition, Cdh1∆Li mice was crossed with LSL-KrasG12D (active Kras) mice and also fed with high fat diet.

**Results:** Cdh1∆Li mice that received a high-fat diet for 7 months increased in body weight similarly to control mice, and the degree of fat deposition in the liver was increased but not different from controls. On the other hand, the extent of cholangiitis and fibrosis, and numbers of bile ductules significantly progressed as compared to normal diet-administered mice. CD44-positive stem cell-like cells were significantly increased and ALT and ALP levels were also increased in mice with high fat diet. Liver specific LSL-KrasG12D/ Cdh1∆Li showed 2-10 macroscopically tumors with both hepatocellular and cholangiocellular components after 9 months of birth with normal diet, whereas high fat diet induced aggressive and numerous numbers of cholangiocellular tumors only after 3 months of high fat diet. Interestingly hepatocellular tumors were rarely found in these mice. In contrast, liver specific LSL-KrasG12D mice showed aggressive hepatocellular tumors by high fat diet.

**Conclusion:** NAFLD exacerabtes cholangiosis and becomes a strong promoter of not only hepatocellular tumors, but also cholangiocellular tumors. In addition, NAFLD may cause transdifferentiation from hepatocellular to cholangiocellular component.

**HCC Optimal Treatment Selection in Hepatocellular Carcinoma**

**HCC10-3**

A personalized approach for optimal treatment selection in HCC

Dr. Yi-Hsiang Huang

Taiwan Liver Cancer Association (TLCA), Institute of Clinical Medicine, College of Medicine, National Yang Ming Chiao Tung University, Healthcare and Services Center, Taipei Veterans General Hospital Taiwan

The treatment of HCC is diverse depending on tumor stage and affordability of patients. A personalized approach remains an unmet medical need. Recently, the application of AI had introduced into the field of HCC management. In our recent study, the risk of recurrence after surgical resection of HCC could be predicted by an evolutionary learning-derived clinical-radiomic GARSL models. This model can further discriminate the risk of recurrence either in high or low risk patients defined by Imbrave 050 study, indicating that the requirement of adjuvant immunotherapy after surgical resection of HCC can be determined by this AI model in our daily practice in near future. TACE unsuitability is an emerging issue for intermediate stage HCC. We have recently proposed a novel 7-11 criteria to divide BCLC B HCC into low-, intermediate-, and high tumor burden; and define the outcomes of TACE through different radiologic patterns, both can assist decision making before TACE. More studies support the concept that the dissimilarities in gut microbiome composition are associated with immune status and susceptibility to immunotherapy. Recently, we identify the associated of gut microbiota and metabolites with outcome of HCC undergoing immune checkpoint inhibitors treatment, supporting the potential role of gut microbiota in selection patients with HCC for immunotherapy.

Development and Prospects of AI-aided Ultrasonography System -New Possibilities in Diagnosis of Liver Tumor-

Dr. Naoshi Nishida

Department of Gastroenterology and Hepatology Kindai University Faculty of Medicine Japan

The integration of artificial intelligence (AI) has aimed to enhance operational efficiency and mitigate human errors in the medical field. Image diagnosis support, a pivotal area for AI development, has witnessed the initiation of large-scale database construction and the deployment of numerous models in society. Notably, liver malignancies stand as the fifth leading cause of cancer-related deaths in Japan, underscoring the urgency of early diagnosis through ultrasonography for improved prognosis and reduced medical costs. However, the variable quality of ultrasound (US) diagnosis, dependent on the skill of examiners, presents a challenge. Hence, achieving AI-assisted standardization in the quality of US examination becomes crucial for effective disease management of malignant liver tumor.

Within the framework of the Japan Agency for Medical Research and Development (AMED)-ICT Infrastructure Development and Artificial Intelligence Implementation Project, we established a system for collecting US images and ancillary information, and developed an AI capable of detecting and discriminating liver masses in abdominal US B-mode examinations utilizing a comprehensive database.

A 2-step method employing YOLOv5 as a mass detector, convolutional neural network (CNN-VGG19) as a tumor discriminator, and DeepSORT to prevent duplicate detection was implemented. The detector demonstrated exceptional performance in pre-clinical tests, surpassing 90% in recall, precision, and F1-score through a 10-fold cross-validation. The discriminator, designed for the differential diagnosis of hepatocellular carcinoma, metastatic hepatocellular carcinoma, hemangioma, and cysts, achieved high accuracy, sensitivity, and specificity in a four-class classification and benign-malignant discrimination in cross-validation.

In an exploratory clinical trial under the AMED-Practical Research for Innovative Cancer Control Project, the performance of prototype AI model integrating detectors and discriminators in series was evaluated to determine the impact of AI-assisted improvement in human US diagnostic performance. The results revealed significant enhancements in liver mass detection indices (recall, precision, F1-score) and differentiation indices (accuracy, sensitivity, specificity, and Matthews correlation coefficient) particularly for non-expert, demonstrating the practical potential of the developed AI model to support human US diagnosis. Research projects are underway to refine and market the AI as Software as a Medical Device (SaMD). In addition, concurrently, efforts are also directed towards developing a model capable of differentiating intrahepatic cholangiocarcinoma.

The effectiveness of our AI in supporting US diagnostics has been recognized, especially among non-experts, where AI assistance has significantly improved all detection and differentiation indices. It can be described as a practical AI model that aids in the diagnosis of liver tumors in human US examinations.
complicated with active HCC may differ between countries due to lack of evidence. These points will be discussed.

HCC Clinical Trials in Hepatocellular Carcinoma: Challenges of Multinational Multicenter Trials

HCC11-1

Dr. Tawesak Tanwandeep
Department of Medicine Faculty of Medicine Siriraj Hospital, Mahidol University Thailand

Hepatocellular carcinoma (HCC), the most common type of primary liver cancer, presents significant therapeutic challenges, particularly in the context of multinational, multicenter clinical trials. There are many challenges and propose strategies for effective management. The complexity of HCC, influenced by underlying liver disease, comorbidities, and diverse etiologies, necessitates a multifaceted approach in clinical research. Multinational, multicenter trials for HCC are pivotal in advancing global understanding and treatment strategies. However, these trials face unique challenges, including variability in clinical practices, regulatory differences, and heterogeneous patient populations. There is disparity in HCC epidemiology, risk factors, and standard care protocols across different countries. Variations in disease presentation and progression, influenced by geographic and genetic factors, further complicate trial design and outcomes analysis. Moreover, there are problems on patient recruitment, adherence to protocols, data collection consistency, and the impact of cultural and linguistic barriers. We underscore the importance of harmonizing regulatory requirements and clinical guidelines to facilitate smoother conduct of these trials. Clinical studies delve into the methodological challenges of ensuring statistical power and validity in such diverse settings. Strategies to overcome these include adaptive trial designs, robust statistical methods to handle heterogeneity, and the use of centralized data monitoring systems.

In conclusion, the complexities inherent in multinational, multicenter clinical trials for HCC are challenging. It advocates for international collaboration, standardization of practices, and innovative trial designs to enhance the efficacy and generalizability of clinical research in the realm of hepatocellular carcinoma.

HCC Clinical Trials in Hepatocellular Carcinoma: Challenges of Multinational Multicenter Trials

HCC11-2

Utilizing Real-world Data for Systemic therapy in Hepatocellular Carcinoma.

Dr. Yoshinari Asaoka
Department of Medicine, Teikyo University School of Medicine Japan

In the current landscape, the escalating costs of drug development not only pose challenges to the development process but also contribute to the rising prices of approved medications. Considering this situation, there is growing anticipation for new drug development utilizing real-world data (RWD). Developing a single novel drug using RWD is not necessarily straightforward. However, it seems possible to develop better treatment sequence by evaluating the effects of treatment sequencing, combination therapies, and their impact on therapeutic outcomes and adverse events.

Systemic therapy for advanced hepatocellular carcinoma (HCC) has made remarkable progress. In Japan, regimens including atezolizumab plus bevacizumab, sorafenib, and lenvatinib were available for first line treatment, and regorafenib, ramucirumab, and cabozantinib for second line until the approval of tremelimumab plus durvalumab in 2022. In real-world clinical practice, treatment is being delivered in a variety of sequences. We launched the Hepatoma Registry of Integrating and Aggregating EHRs (electric health record): HERITAGE study to establish a registry of RWD in Japan. In this study, among the HCC cases registered in the nationwide follow-up survey of primary liver cancer conducted by Japan Liver Cancer Association, cases treated with systemic therapy between 2015 and 2022 were included. We will show the RWD of systemic therapy for HCC in Japan, including changing patient characteristics, treatment sequences, and treatment efficacy.

HCC Unraveling the Progression of Genomic Anomalies in Hepatocellular Carcinoma

HCC12-3

Integrated Omics Analysis for the Progression of Hepatocellular Carcinoma

Dr. Shintani Tanaka
Department of Molecular Oncology, Tokyo Medical and Dental University Japan

Recent advances in gene analysis technologies such as next-generation sequencing system have facilitated genome-wide investigation in various cancers including hepatocellular carcinoma (HCC). Comprehensive and un-supervised transcriptomic analysis has been conducted, revealing that HCC samples can be divided into several subtypes with distinct gene expression patterns. Additionally, genome and exome analysis through next-generation sequencing, as well as methylome, metabolome and proteome analysis using methylation array and mass spectrometry, have been conducted. During this period, the "two-class" model, categorizing HCC into proliferative and non-proliferative classes, was proposed. Publicly available data including mutation signatures and expression profiles of hundreds of HCC cases were generously provided by the Cancer Genome Atlas (TCGA) and International Cancer Genome Consortium (IGC) Research Network, advancing the understanding of the relationship between the subtypes, clinicopathological factors, and tumor microenvironment including vascular endothelial cells and immune cells. On the other hand, since the approval of antiangiogenic agent sorafenib, treatment options have been lacking due to a series of clinical trial failures for nearly 10 years. However, other antiangiogenic inhibitors including regorafenib, lenvatinib, cabozantinib and antiangiogenic antibodies have emerged, followed by combination of immune checkpoint inhibitors, which can ameliorate progression-free and overall survival in HCC patients. Nevertheless, starting with the clinical report that HCC with CTNNB1 active mutations conferred potential resistance to immune checkpoint blockade, investigations on the link between the subtypes and drug response are ongoing by further use of single-cell gene analysis. In the same period as such development in genome-based medicine, it has coincided with the acceleration of remarkable innovations in genome-editing technology using the CRISPR/Cas9 system. The integration of comprehensive genome editing technologies, such as multiplex genome editing, which introduces multiple genomic aberrations simultaneously, with barcode sequencing technology has led to the development of in vivo screening methods, allowing preclinical models that mimic each subtype to be individually reproduced. Immunocompetent subtype models reflect the molecular characteristics of the subtype and the tumor immune microenvironment and can help evaluate the efficacy of single and combination therapies and understand the molecular and immunological mechanisms underlying vulnerability and resistance to them. Thus, consensus classifications and associated preclinical models are extremely promising for establishing predictive
biomarkers and escalating the clinical development of subtype-specific therapies.

HCC Unraveling the Progression of Genomic Anomalies in Hepatocellular Carcinoma
HCC12-4

Unraveling the Progression of Genomic Abnormalities in Hepatocellular Carcinoma

Dr. Pei-Jer Chen
Hepatitis Research Center National Taiwan University & Hospital Taiwan

The natural history of hepatocellular carcinoma presumably evolves from initial chronic hepatitis, subsequent cirrhosis and eventually HCC. In analogous to most human cancers, genomic mutations gradually appear and accumulate during the process, and finally lead to HCC. However, so far we still cannot chronicle the time-sequences of the incriminated mutations in details.

Most of known common genetic mutations of human HCC, irrespective of etiology, such as TERT promoter mutations, p53 or beta-catenin, or ARID gene mutations, occur in the late stage, from dysplastic nodules to early HCC. In the non-dysplastic cirrhotic nodules, WGS failed to identify recurrent genetic mutations. Therefore, we still do not know what mutations drive the clonal expansion in the cirrhosis stage.

One exception to this is noted in HBV-related HCC in which HBV DNA integration takes place in the very early stage of viral infection or hepatitis, probably 20-30 years before the development of HCC. DNA integration occurs in the very early stage of viral infection and eventually leads to HCC. In analogous to most human cancers, genomic mutations gradually appear and accumulate during the process, and finally lead to HCC. However, so far we still cannot chronicle the time-sequences of the incriminated mutations in details.

HCC Tumor Microenvironment in Hepatocellular Carcinoma
HCC13-3

Understanding microenvironment of hepatocellular carcinoma for biomarkers and therapeutic discovery

Dr. Valerie Chew
Translational Immunology Institute (TII), Sing Health Duke-NUS Medical School Taiwan

Despite recent success in cancer immunotherapies, the complex dynamics within tumor-immune microenvironment (TIME) remain elusive. With the multidimensional analysis pipeline, we have successfully identified and described key immunological factors in hepatocellular carcinoma (HCC) that contribute to disease progression and clinical response to therapy. Our team has identified peripheral immunological biomarkers associated to therapeutic response in HCC patients treated with radiotherapy and anti-PD-1 immunotherapy, shedding light on potential mechanism for treatment response and guiding the design of novel therapeutic strategies. More recently, we have explored the immune landscape of steatotic-related HCC to uncover potential mechanisms driving immunosuppression and to identify novel immunotherapeutic targets.

ACLF 1. Recent Changes of Incidence and Etiology of Acute Liver Failure in Asia Pacific Region
ACLF1-3

Recent changes of incidence and epidemiology of acute liver failure in Asia-Pacific region

Dr. Nobuaki Nakayama
Department of Gastroenterology & Hepatology, Saitama Medical University Japan

There is no international registry of acute liver failure (ALF) in the Asia-Pacific region. Instead, data on the outcomes of ALF are available by referring to published studies on ALF evaluated in nationwide surveys and at individual centers. In Asia, viral hepatitis has been the main cause of ALF; however recent publications suggest that the incidence of ALF due to drugs and herbs is increasing in most countries (Jindal et al., 2022). Pan Zhao et al. reported in 2013 that traditional Chinese medicine was a major cause of ALF in China. In India, HEV was the etiology of ALF in 419 (28.7%) cases, whereas non-A non-E hepatitis, HBV, and antituberculosis therapy were the etiologies in 527 (36.0%), 128 (8.8%), and 103 (7.0%) cases, respectively (Shalimar et al., 2017). A large study by the Indian DILI Network disclosed that antituberculosis drugs (62.9%) were the most common types of drugs that had caused ALF (Devabhakti et al., 2021). In South Korea, according to the prevalence of HAV infection, the number of HAV ALF cases requiring liver transplantation were increasing (Kim, 2010). In Australia, paracetamol was the most common etiology of ALF, accounting for 49.7% of cases (Hey et al., 2019).

The Intractable Hepato-Biliary Diseases Study Group of Japan conducted a nationwide survey on ALF and late-onset hepatic failure (LOHF) since 2011. Until 2011, they had performed such surveys on fulminant hepatitis and LOHF. A total of 2,368 patients with fulminant hepatitis and/or acute liver failure (acute and subacute) and 172 patients with LOHF were enrolled in nationwide surveys. In cases seen from 1998 to 2009, the viral etiology in the acute type of hepatitis accounted for 67.4%, whereas from 2010 to 2015, it decreased to 32.7% for overall cases of the acute type and 43.8% for hepatitis cases specifically. In the years 2016 to 2021, the respective percentages further declined to 26.9% and 39.1%, indicating a continued decrease in viral etiology rates. During that period, HBV was the etiology for 92 cases, representing 15.9% of the total cases of ALF (acute and subacute) and LOHF, and 20.2% of hepatitis cases. In cases of hepatitis, the ratios of autoimmune and drug-induced etiologies were 8.1% and 11.6%, respectively, for the period 1998 to 2009. However, in the years 2010 to 2015, these ratios increased to 14.4% and 11.0%, and further rose to 16.9% and 16.6% during the period from 2016 to 2021.

ACLF 1. Recent Changes of Incidence and Etiology of Acute Liver Failure in Asia Pacific Region
ACLF1-4

Japanese style artificial liver support system

Dr. Kazuaki Inoue
Department of gastroenterology, International University health and welfare Narita Hospital Japan

Japan is a country where blood purification therapy is most advanced than any other countries in the world. The reason for this is the development of Japanese industrial technology and the harsh environment surrounding transplant medicine. In Japan, blood purification therapy that can keep a patient awake and in a stable condition is essential. In the Japanese medical environment, a requirement for blood purification therapy is the ability to reliably awaken patients and maintain...
them in a stable state. The method developed for this purpose is blood purification therapy that combines plasma exchange and hemodiafiltration. The characteristics of hemodiafiltration are that blood is purified using a large amount of replacement fluid and that blood purification takes a long time. Even though method of hemodiafiltration is the same, the conditions are very different from those used for renal replacement therapy. Since using this treatment, most patients have recovered from coma, and it is now possible to safely maintain them until their own livers regenerate or a suitable donor is found. Today, the number of elderly patients with comorbidities is increasing, and it is difficult to perform dialysis under strict dialysis conditions for such patients. Due to these circumstances, there are a certain number of patients with acute liver failure who do not undergo blood purification in recent years. In the future, it is necessary to improve vascular access and develop blood purification therapy that is easy to do.

ACLF 2. Treatments and Prognosis of ACLF in Asia Pacific Region

ACLF 2-2

Management of vascular disorders in patients with ACLF

Dr. Akash Shukla
Gastroenterology, Seth GS Medical College & KEM Hospital, Hepatology, Sir HN Reliance Foundation Hospital, Mumbai India

Vascular liver diseases like portal vein thrombosis (PVT) or Budd Chiari syndrome (BCS) may present with acute on chronic liver failure (ACLF). The possible associations of PVT with ACLF (PVT-ACLF) have been recently described and the principles of management of these patients proposed. The treatment options for PVT in this setting would include observation, anticoagulation and/or radiological interventions like thrombolysis and thrombectomy. The choice of therapy would depend upon the extent of thrombosis and the clinical consequences of PVT. The other vascular disease is BCS, where association with ACLF (BCS-ACLF) and its management is described. While we know that acute on chronic BCS is associated with poor outcomes, there is recent data on clinical features and management of BCS-ACLF. In patients with ACLF where the acute event is vascular thrombosis like PVT or hepatic vein thrombosis (HVT), there is a potential for reversibility of liver failure, especially in the 'golden window', similar to other ACLF, and all attempts need to be made towards urgent revascularization of these vein(s), while in patients with pre-existing BCS or cirrhosis with PVT who present with ACLF, liver transplant may be the best option.

ACLF 3. Liver Regeneration up to date

ACLF 3-1

Revolutionising Liver Health: The Science and Potential of Liver Regeneration

Dr. Kuo-Chao Yew
Gastroenterology and Hepatology Department Tan Tock Seng Hospital Singapore

The liver’s extraordinary regenerative capability, coordinated by the intricate "Hepatostat" system, maintaining a consistent liver-to-body-weight ratio, sets it apart from other organs. Prominently demonstrated in partial hepatectomy, this regenerative capability offers profound insights into harnessing natural regenerative potential and serves as a tissue engineering model. However, chronic liver diseases disrupt this equilibrium, causing hepatocyte depletion, hepatic stellate cell activation, and collagen buildup, while genotoxic environments can trigger liver oncogenesis through cellular diploidy induction.

In contemporary times, significant strides have been taken in comprehending cellular kinetics, histological transformations, and signalling pathways pivotal in liver regeneration. Moreover, understanding zon-specific initiation unravels the precise orchestration of diverse soluble factors governing liver zonation. The identification of progenitor cells opens doors to innovative therapies involving cellular, drug, and gene manipulation. Excitingly, the past decade has witnessed breakthroughs such as bioengineered livers for disease modelling, 3D printing in liver transplantation, and integration of artificial intelligence, signifying newfound enthusiasm in the field. This lecture delves into the potential of liver regeneration, providing a glimpse into the promising future of Hepatology.

ACLF 3. Liver Regeneration up to date

ACLF 3-3

Development of Regenerative Therapy for Liver Cirrhosis - Mesenchymal stem cells, HMGB1 peptide, extracellular vesicles-

Dr. Shuji Terai
Division of Gastroenterology & Hepatology, Graduate School of Medical and Dental Sciences, Niigata University Japan

We have been developing regenerative therapies for liver cirrhosis. The liver is a regenerative organ, but fibrosis reduces its regenerative capacity, and a clinical study in 2003 and a subsequent multicenter clinical study (Autologous bone marrow cell infusion therapy) showed that improvement of fibrosis induces regeneration in patients with non-compensated liver cirrhosis. Subsequently, since 2015, conducted a clinical trial for cirrhosis using allogeneic mesenchymal stem cells. From a series of basic studies, the mechanism was clarified that mesenchymal stem cells administered from peripheral blood vessels populated mainly to the lungs, where they emit extracellular vesicles, making macrophages anti-inflammatory, improving fibrosis, and inducing regeneration. Furthermore, extracellular vesicles obtained by induction of mesenchymal stem cells with IFNγ were found to be useful for improving fibrosis and inducing regeneration. On the other hand, the optimization of the liver fibrosis evaluation method in clinical trials for liver cirrhosis has also been clarified by conducting clinical trials of mesenchymal stem cells and HMGB1 peptide as a corporate clinical trial and an investigator-initiated clinical trial. In the future, we are preparing to establish an international standard for how extracellular vesicles can be used as a treatment that maintains clear quality in terms of Mode of Action. In this presentation, we will present the future perspective of a new regenerative therapy for liver cirrhosis.
for the treatment of end-stage liver disease. A shortage of suitable organs, high costs and surgical complications limit the application of liver transplantation. Nowadays, stem cell therapy gained more and more attention due to its attractive efficacy in treating liver disease especially in cirrhosis during the clinical trials. Due to the regenerative properties of the liver, various kinds of cell therapies using hepatocytes, hematopoietic stem cells, bone marrow mononuclear cells, and mesenchymal stem cells (MSCs) are being investigated as alternative treatments to liver transplantation.

Among them, Mesenchymal stem cell therapy has been considered as a promising alternative approach for end-stage liver disease, because they show potential to regenerate injured tissues or organs, such as homing, transdifferentiation, immunosuppression, and cellular protective capacity.

Some clinical trials have confirmed the effectiveness of MSC therapy for liver disease, but currently, there is no approved MSC therapy for the treatment of liver disease, because the types of liver disease that are most suitable for MSC application should be determined, and the preparation and engraftment of MSCs should be standardized. These may be bottlenecks that limit the use of MSCs. More robust preclinical and clinical studies will be needed for the key factors such as cytokines, genetic modification, and tissue engineering treatments for liver diseases. In the future, each method has its advantages and challenges, and researchers continue to explore the most effective and safe approaches for liver regeneration using MSCs.

PH Elastography: Current Strategy for Practical Care

**PH1-1**

**Role of Elastography in Hepatitis Elimination**

**Dr. Grace Lai-Hung Wong**

Medical Data Analytics Centre (MDAC), Center for Liver Health, Faculty of Medicine, Department of Medicine and Therapeutics The Chinese University of Hong Kong Hong Kong SAR, China

Elastography is one of the most popular noninvasive assessments of liver fibrosis in patients with chronic viral hepatitis. Specifically, Vibration controlled transient elastography (VCTE) is now an integral part of the clinical care pathway of chronic viral hepatitis in order to determine the prognosis, the need of treatment, as well as monitor disease progression and response to treatment. As alanine aminotransferase (ALT) is one of the major confounding factors of liver stiffness in chronic hepatitis B, an ALT-based algorithm has been developed and higher liver stiffness measurements (LSM) cutoff values for different stages of liver fibrosis should be used in patients with elevated ALT levels up to 5 times of the upper limit of normal. Otherwise falsely-high LSM results up to cirrhotic range may occur during ALT flare. VCTE is also useful in predicting patient prognosis such as development of hepatocellular carcinoma (HCC), portal hypertension, post-operative complications in HCC patients, and also survival. Failed acquisition of VCTE may happen up to 25% in obese patients. Furthermore, obese patients may have higher LSM results even in the same stage of liver fibrosis. The XL probe, a larger probe with lower ultrasound frequency and deeper penetration, increases the success rate of VCTE in obese patients. The median LSM value with XL probe was found to be lower than that by the conventional M probe, hence cutoff values approximately 1.2 to 1.3 kPa lower than those of M probe should be adopted. Recent studies revealed a novel ultrasonic controlled attenuation parameter (CAP) of the machine is a useful parameter to detect even low-grade steatosis noninvasively. CAP may also be used to quantify liver steatosis by applying different cutoff values. As both LSM and CAP results are instantly available at same measurement, this makes VCTE a very convenient tool to assess any patients who are at risk or confirmed to suffer from chronic liver diseases.

**PH1-3**

Clinical utility of the liver and spleen stiffness measurement in the patients with portal hypertension

**Dr. Masashi Hirooka**

Department of Gastroenterology and Metabolism, Ehime University Graduate School of Medicine Japan

Portal hypertension is a critical condition often associated with complications such as varices and ascites, making measurement of the hepatic venous pressure gradient (HVPG) a well-established surrogate marker. HVPG measurement allows prediction of complications associated with cirrhosis, including varices and ascites. According to the Baveno VII criteria, liver stiffness measurement (LSM) plays a crucial role in the diagnosis of clinically significant portal hypertension (CSPH). LSM values below 10 kPa effectively rule out compensated advanced chronic liver disease (cACLD), while LSM values between 15 kPa and a platelet count of 150,000 or greater may rule out CSPH. LSM values above 25 kPa suggest the presence of CSPH. However, the challenge lies in the "gray zone" cases that cannot be definitively categorized using these criteria.

**Unraveling the Pathophysiology of ICI-Induced Immune-Mediated Hepatotoxicity through a Comparison with Autoimmune Hepatitis**

**Dr. Hayato Nakagawa**

Department of Gastroenterology and Hepatology, Mie University Japan

Autoimmune hepatitis (AIH), although a well-known disease, still lacks sufficient understanding of its pathogenesis. Additionally, there is a need for the development of biomarkers, especially for cases resistant to steroids or experiencing relapse. On the other hand, advancements in cancer immunotherapy have brought forth a new concern—immune-mediated hepatotoxicity induced by immune checkpoint inhibitors (ICI), known as ICI-induced immune-mediated hepatotoxicity (IMH). Given its recent emergence, the pathophysiology of IMH remains unclear, and established treatment methods are yet to be defined. While steroids are the primary choice for IMH treatment, resistance cases are frequent compared to AIH. In such instances, empirical recommendations include agents like mycophenolate mofetil, but definitive evidence is lacking.

The anticipation of the growing importance of immunotherapy in the future underscores the urgency for understanding the pathophysiology of these conditions. As part of our efforts in what we term "next-generation precision medicine," we have conducted multi-omics analyses using liver tissues from AIH patients for pathophysiological insights and biomarker development. Currently, we are integrating multi-omics data, including liver biopsy samples from IMH, which shares commonalities with immune-related liver disorders. Through this comprehensive analysis, incorporating the transcriptome data from AIH alongside IMH samples, we aim to elucidate the pathophysiology of both conditions and identify biomarkers. In this session, I will present a portion of this data.
To overcome this limitation and reduce the gray area, markers that correlate better with HVPG than LSM are needed. The spleen, which is emerging as a potential marker, shows a promising role in the assessment of HVPG. Spleen stiffness measurement (SSM) has been reported to correlate better with HVPG than liver stiffness and various fibrosis markers, with a high predictive ability for high-risk esophageal varices.

Our research group, the Spleen Stiffness-IPD-MA Study Group, conducted a systematic review and meta-analysis of individual patient data and reported the favorable diagnostic performance of the Baveno VII SSM criteria. Despite the promising results, accurate measurement of SSM poses challenges compared to LSM. Proper measurement techniques, including the use of new devices and accurate assessment of low controlled attenuation parameter (CAP) values, can improve the reliability of SSM measurements.

In conclusion, our findings suggest the potential of SSM as a valuable marker in the prediction of portal hypertension complications when added to LSM.

PH Management of Portal Hypertension: Standard and Beyond
*PH2-1*

**Innovation Management in Portal Hypertension: Standard and Beyond**

**Dr. Cosmas Rinaldi Adithya Lesmana**

Department of Internal Medicine, Hepatobiliary Division, Dr. Cipto Mangunkusumo National General Hospital, Medical Faculty Universitas Indonesia, Indonesia

Portal hypertension (PH) is still a challenging condition in daily practice as it carries a lot of complications, such as the presence of vascular complication (esophageal varices/EV, gastric varices/GV, gastric antral vascular ectasia/GAVE, gastropathy, colopathy, rectal varices), ascites, hepatic encephalopathy, hepatorenal syndrome, and hepatopulmonary syndrome. The diagnosis of PH is confirmed when the portal pressure reaches 5 mmHg and above. Clinically significant portal hypertension (CSPH) is the most important condition in liver cirrhosis (LC) patients, as it can predict the possible complications arise, and to decide further management including porto-systemic shunting procedure and liver transplantation. However, the gold standard for PH is the indirect measurement, hepatic vein pressure gradient (HVPG) measurement. Even though this procedure is considered as a safe and minimally invasive, but possible adverse events, such as bleeding, pain, infection, and perforation could still happen. It is not always accurate in the setting of non-cirrhotic portal hypertension condition. This procedure is also cannot be performed concomitantly with esophagogastroduodenoscopy (EGD) procedure.

Recently, endoscopic ultrasound (EUS) has been developed for managing liver disease condition. There have been innovations in measuring portal pressure using a novel manometer as well as standard manometer. EUS can be used for portal pressure gradient measurement, where it is a direct measurement, and it can be done with other innovation procedures, such as EUS-guided liver biopsy, EUS-guided vascular injection, and EUS-guided radiofrequency ablation (RFA) for liver tumor. It would need a special training and further validation before it can be recommended as the first-line approach in the future.

**PH Cross Talk with Multiple Organs in Cirrhosis
*PH3-1***

**Impact of 2022 ESC/ERS diagnostic criteria for pulmonary hypertension in cirrhotic patients with portal hypertension in Japan**

**Dr. Masanori Atsunori**

Division of Gastroenterology and Hepatology, Nippon Medical School Hospital Japan

Portopulmonary hypertension (PoPH) is defined as PAH associated with portal hypertension. So far, conventional PoPH was defined as a mean pulmonary artery pressure (mPAP) ≥ 25 mmHg, pulmonary vascular resistance (PVR) > 3 Wood units (WU), and pulmonary arterial wedge pressure (PAWP) ≤ 15 mmHg according the previous diagnostic criteria, whereas in 2022, the European guideline for pulmonary hypertension revised the hemodynamic definition of pulmonary hypertension in pre-capillary PH by lowering the mPAP to > 20 mmHg and the PVR to > 2 WU. From now on, prevalence of patients with PoPH according to the new guideline may change among cirrhotic patients with portal hypertension. At Nippon Medical School, 186 patients with liver cirrhosis and portal hypertension were subjected and underwent right heart catheterization in this analysis. The median mPAP, PVR and PAWP were 12.9 mmHg (range, 6.6–40.8), 0.8 WU (range, 0.1–4.5) and 7.5 mmHg (range, 2.2–15.4) respectively. For both diagnostic criteria, many of the 186 patients were below the cut-off values for both mPAP and PVR, respectively (conventional, n = 184; new, n = 182). Two (1.1%) patients had conventional PoPH. In addition, two patients that were not diagnosed as PoPH by the conventional diagnostic criteria, many of the 186 patients were below the cut-off values for both mPAP and PVR, respectively (conventional, n = 184; new, n = 182). Two (1.1%) patients had conventional PoPH. In addition, two patients that were not diagnosed as PoPH by the conventional diagnostic criteria were included in the PoPH range by the new diagnostic criteria. For each diagnostic criteria, there were no patients that met only one criterion of mPAP and PVR, and were divided into two groups. mPAP and PVR were significantly but weakly correlated (p = 7.44 × 10-5, r = 0.286). With the new diagnostic criteria of PoPH, there were patients that were not diagnosed with PoPH by conventional diagnostic criteria, resulting in an increase in the number of patients diagnosed with PoPH from 1.1% to 2.2% in this cohort. In particular, it is possible that the change in the cut-off value of PVR was particularly important, since patients with a PVR of 2 to 3 WU were newly diagnosed. As new diagnostic criteria are likely to be adopted in Japan in the future, the number of patients diagnosed with PoPH is expected to increase.

**PH Noncirrhotic Portal Hypertension: Current Status and Problem
*PH4-1***

**Non cirrhotic portal hypertension: Current status and problem**
Non-cirrhotic portal hypertension (NCPH) refers to a heterogeneous group of liver disorders characterized by portal hypertension, splenomegaly, hypersplenism, and cytopenia in absence of liver cirrhosis. It has been referred to by different names over time such as non-cirrhotic portal fibrosis (Indian subcontinent), hepatopetal sclerosis (West), and idiopathic portal hypertension (Japan). NCPH is diagnosed after excluding other causes of portal vein or hepatic venous outflow tract obstruction. The disease progresses through different phases with symptoms ranging from splenomegaly and anemia to complications of portal hypertension such as gastrointestinal bleeding, ascites.

Later, the term idiopathic non-cirrhotic portal hypertension (INCPH) was proposed by a consensus of experts who introduced a common nomenclature and diagnostic criteria: essentially, the presence of an unexplained portal hypertension and the absence of cirrhosis in liver histology.

Recently, in order to overcome those difficulties and to reach a uniformity in the nomenclature, the term Porto-Sinusoidal Vascular Disease (PSVD) has been proposed by the European Association for the Vascular Liver Disease. Now it is not limited to the exclusion criteria but provides positive diagnostic criteria. The new diagnostic criteria define the diagnosis of PSVD in presence of one of the three following features:

1. At least one specific sign of portal hypertension (gastroesophageal varices, or ectopic varices, porto-systemic collaterals, bleeding due to portal hypertension) in the absence of cirrhosis at an liver biopsy.
2. At least one specific histological sign of PSVD (obliterative portal venopathy, nodular regenerative hyperplasia, incomplete septal fibrosis or cirrhosis) and absence of cirrhosis at liver biopsy. As per this criteria there may be absence of signs of portal hypertension;
3. At least one non-specific sign of portal hypertension (ascites, low platelets, splenomegaly) at an adequate liver biopsy and in addition to at least one non-specific histological sign of PSVD (portal tract abnormalities: multiplication, dilation of arterioles, periportal vascular channels, and aberrant vessels; architectural disturbance: irregular distribution of the portal tracts and central veins; non-zonal sinusoidal dilatation; mild perisinusoidal fibrosis) and to the absence of cirrhosis.

The exact cause of INCPH or PSVD remains a mystery, prompting ongoing research. There are no specific tests. Instead, accurate diagnosis relies on a high-quality liver biopsy, and the skilled interpretation of a pathologist. Notably, no treatments specifically aimed at controlling the disease progression have been explored. Currently, the treatment relies on the prevention of complications related to portal hypertension, following current guidelines of cirrhotic portal hypertension.

Etiology and Pathophysiology
NCPH can arise from a variety of causes, including vascular disorders like portal vein thrombosis, splenic vein thrombosis, or Budd-Chiari syndrome; structural abnormalities like schistosomiasis; and systemic diseases such as sarcoidosis and autoimmune hepatitis. Unlike cirrhotic portal hypertension, where the primary issue is increased resistance to blood flow within the liver, in NCPH, the resistance may occur pre-hepatically (before the liver), intrahepatically (within the liver but not due to cirrhosis), or post-hepatically (after the liver).

The pathophysiology of NCPH involves the disruption of normal portal venous flow due to these varied causes, leading to increased portal pressure. This increase in pressure can lead to the development of collateral vessels and splenomegaly, among other complications.

Clinical Manifestations
Patients with NCPH may present with a range of symptoms. The most common manifestation is gastrointestinal bleeding, typically from esophageal or gastric varices, similar to what is seen in cirrhotic patients. However, patients with NCPH often have preserved liver function. Other presentations can include splenomegaly, ascites (less common than in cirrhosis), and features of hypersplenism like pancytopenia.

Diagnosis
Diagnosis of NCPH requires a combination of clinical, laboratory, and imaging findings. Liver function tests are typically normal or show only mild abnormalities. Imaging studies, such as Doppler ultrasound, CT scan, or MRI, are critical for identifying the site and cause of the increased portal pressure. In some cases, a liver biopsy may be necessary to exclude cirrhosis and to identify intrahepatic causes of NCPH.

Management
Management of NCPH focuses on treating the underlying cause, if identified, and managing complications. Primary prevention of variceal bleeding is essential and can be achieved through pharmacotherapy (e.g., beta-blockers) or endoscopic interventions. In cases of variceal bleeding, endoscopic therapy is the mainstay of treatment. Additionally, management of hypersplenism and its hematologic complications may be necessary.

In cases where medical management is inadequate, surgical options such as shunt surgeries or even liver transplantation may be considered, depending on the underlying pathology and patient’s overall condition.

Conclusion
Non-cirrhotic portal hypertension is a complex condition with diverse etiologies and manifestations. Its management requires a thorough understanding of its pathophysiology and a multidisciplinary approach. Early recognition and appropriate intervention are key to improving outcomes in patients with NCPH. Further research is needed to better understand this condition and to develop more effective management strategies.
First, we performed a meta-analysis of randomized controlled trials (RCTs) to examine the effects of exercise on physical function and serious events in patients with liver cirrhosis. A literature search was conducted in 2022. Eleven RCTs were selected for the meta-analysis (exercise group, n=232; control group, n=193). A meta-analysis was performed using a random-effects model. In the eleven RCTs, a meta-analysis demonstrated the 6-minute walking distance significantly improved in the exercise group compared with the control group. Moreover, in a stratification analysis based on a combination of aerobic and resistance exercise, the incidence of serious events was 6.25% and 24.7% in the combination exercise and control groups, respectively. A meta-analysis demonstrated a significant reduction in the incidence of serious events in the combination exercise group compared with the control group.

Next, we investigate the effects of exercise on the prognosis of patients with HCC. We performed a prospective observational study, which analyzed 152 patients with HCC who underwent transcatheter arterial chemoembolization (TACE). Patients were classified into the exercise (n=85) and control (n=67) groups. Independent factors associated with survival were evaluated by Cox regression analysis. There were no exercise-related severe adverse events throughout the study periods. Along with Child-Pugh class A, “exercise” was identified as an independent factor associated with survival in Cox regression analysis. The survival rate was significantly higher in the exercise group than in the control group.

In conclusion, we demonstrated that exercise improved physical function in patients with liver cirrhosis. We further demonstrated that resistance exercise in combination with aerobic exercise reduces serious events in patients with liver cirrhosis by a meta-analysis of RCTs. Moreover, in patients with HCC, exercise had beneficial effects on the prognosis with no worsening of liver function. These findings suggest that exercise therapy should be considered a fundamental therapy for patients with both liver cirrhosis and HCC.

PH Liver fibrosis: from Bench to Bedside

PH6-1

Liver Fibrosis & Portal Hypertension: Molecular Mechanisms and Therapeutic Opportunities

Dr. Jordi Gracia-Sancho
Hepatology, IDIBAPS - Hospital Clinic de Barcelona - CIBEREHD Spain

Portal hypertension represents one of the major clinical consequences of chronic liver disease, having a deep impact in patients’ prognosis and survival. Its pathophysiology defines a pathological increase in the intrahepatic vascular resistance as the primary factor in its development, being subsequently aggravated by a paradoxical increase in portal blood inflow. Elevation in vascular resistance derives from de-regulations in hepatic cells function, which leads to the development of intrahepatic vascular dysfunction and fibrosis. Additionally, now we know that hepatic mechanobiological cues actively contribute to aggravate and perpetuate portal hypertension. Hepatic microvascular dysfunction occurs early in the course of chronic liver disease as a consequence of inflammation and oxidative stress and determines loss of the normal phenotype of liver sinusoidal endothelial cells (LSEC) that become proliferative, pro-thrombotic, pro-inflammatory and vasoconstrictor. The cross-talk between LSEC and hepatic stellate cells (HSC) induces activation of the latter, which in turn proliferate, migrate and increase collagen deposition around the sinusoids, contributing to fibrogenesis, architectural disruption and angiogenesis, which further increase the hepatic vascular resistance and worsen liver failure by interfering with the blood perfusion of the liver parenchyma. Moreover, recent data suggest that the phenotype of liver cells could be further impaired due to the altered mechanical properties of the cirrhotic liver itself, therefore creating a deleterious vicious cycle that would further worsen portal hypertension in advanced stages of the disease. This lecture will critically summarize the current knowledge in portal hypertension pathophysiology, focusing on the intrahepatic mechanisms leading to fibrosis and vascular dysfunction development.
Dr. Hong Soo Kim
Soon Chun Hyang University Hospital, Internal medicine Korea
Metabolic dysfunction–associated fatty liver disease (MAFLD) is the most common cause of chronic liver disease worldwide. MAFLD includes a wide spectrum of liver injury including simple steatosis and non-alcoholic steatohepatitis (NASH) that may lead to serious complications such as liver cirrhosis and liver cancer.

The identification of Nonalcoholic steatohepatitis (NASH) or NAFLD is clinically important because NASH indicates an increased risk for fibrosis progression and the need for aggressive treatment and closer follow-up. Population based study suggests that NAFLD is becoming an important cause of HCC, and these rates are increasing by approximately 10% per year. So we needs follow up guideline of patients with NAFLD but there is no accepted consensus on the optimal strategy for monitoring patients with NAFLD and their response to treatment.

According to The Asian Pacific Association for the Study of the Liver clinical practice guidelines for the diagnosis and management of metabolic associated fatty liver disease, patients with NAFLD may need a FibroScan yearly or once every three years. The frequency is dependent on your previous FibroScan results. It is important to distinguish mild (F1-F2) from advanced or severe (F3-F4) fibrosis, as patients with severe fibrosis have a greater risk of complications and need to undergo screening for hepatocellular carcinoma with NAFLD.

Endoscopic Treatment for Esophageal and Gastric Varices in Japan

Dr. Takuto Hikichi
Department of Endoscopy, Fukushima Medical University Hospital Japan

Esophageal varices (EVs) and gastric varices (GVs) are treated with drug therapy, interventional radiology, and surgical operation, but endoscopic treatment is the mainstay of treatment for patients with bleeding or high risk of bleeding.

Endoscopic treatment for EVs is widespread worldwide, and endoscopic variceal ligation (EVL) is widely used not only for bleeding cases but also for prophylactic cases. In Japan, endoscopic injection sclerotherapy (EIS) using intravariceal injection with ethanolamine oleate (EO) as a sclerosant agent has long been used for prevention of EV rupture. EIS is a treatment to embolize the inflow from portal vein that forms EVs, and theoretically has a low recurrence rate. However, due to the complexity and difficulty of the procedure, an increasing number of centers in Japan are using EVL as the main EV treatment, and EIS is now limited to high-volume centers. To reduce the EV recurrence rate by intravariceal EIS alone, extravariceal EIS with polidocanol has been used after intravariceal EIS. In addition, argon plasma coagulation (APC) after intravariceal EIS or extravariceal EIS is also used in Japan. At our institution, we are trying ablation using high-frequency hemostats as an alternative to APC. As a device for endoscopic treatment of EVs, EIS with ligation, in which the variceal puncture site is ligated during EIS, and EIS with ligation of the perforating vein that causes an extraesophageal shunt have also been performed. Recently, Furuichi et al. reported a technique for reliable intravariceal EIS using red dichromatic imaging, a kind of image enhanced endoscopy (IEE), to estimate the wall thickness and depth of EVs. Moreover, we have been using a technique to improve the success rate of variceal puncture by injecting gel into the esophageal lumen and using texture and color enhancement imaging, which is a kind of IEE.

The Sarin classification is a well-known endoscopic classification of gastric varices (GVs), based on the continuity with EVs and the location of GVs, and is divided into four categories: GOV (gastroesophageal varices)-1, GOV-2, IGV (isolated gastric varices)-1, IGV-2. Among them, GOV-1 is a varix flowing from the gastric cardia to the esophagus, and is defined as EVs in Japan. On the other hand, the Japan Society for Portal Hypertension classifieds GVs into Lg-c, Lg-cf, Lg-f, Lg-a, and Lg-b. Lg-c is a varix localized at the gastric cardia, Lg-cf is a varix extending from the cardia to the fornix, and Lg-f is a varix localized at the gastric fornix. Lg-c, Lg-cf, and Lg-f correspond to IGV-1, and Lg-a and Lg-b correspond to IGV-2. In the following, EVs are defined as those corresponding to IGV-1. Endoscopic treatment for GVs is mainly endoscopic cyanoacrylate injection with N-butyl-2-cyanoacrylate (NBCA). In cases of GV hemorrhage, endoscopic cyanoacrylate injection with NBCA is preferred over EVL because of the rapid blood flow. In addition, we have been using endoscopic cyanoacrylate injection combined with intravariceal EIS with EOI for prevention of GV rupture. The GV is occluded by NBCA and the inflow is embolized by EO. Furthermore, Irisawa et al. reported the combination of endoscopic-guided coil deployment and intravariceal EIS for prevention of GV rupture.

I will give a presentation on the current status of endoscopic treatment of EVs and GVs in Japan.

Portal Hypertension in unusual condition

Dr. Sudhamshu K C
Department of Hepatology, National Academy of Medical Sciences Nepal

Portal hypertension (PH) is defined as increased blood pressure in the portal venous system above 5 mg. Portal hypertension is classified as prehepatic, intrahepatic, and posthepatic. While cirrhosis dominates as the leading cause of PH in routine practice, NCPF and even rarer conditions can also appear in clinical settings. This presentation delves into PH seen in these less common scenarios. Following are the conditions where we can encounter PH.

1. Arteriovenous malformations (AVMs)
2. Nodular regenerative hyperplasia (NRH)
3. Pseudocirrhosis
4. Hepatic fibrosis
5. Hepatic amyloidosis

First described in 1886 by Weigert, AVMs are generally uncommon, certain types can indeed contribute to PH. AVMs can be intraparenchymal or extraparenchymal. Extraparenchymal can be of two main types namely mesenteric AVMs and splenic AVMs. Hepatic arterioportal fistulas (HAPFs) are intraparenchymal causes of AVMs. It is usually categorized into three classes, as follows: Type 1: small peripheral intrahepatic; Type 2: large central HAPF; and Type 3: diffuse congenital intrahepatic.

NRH is a rare liver disease characterized by the abnormal growth of small, regenerative nodules throughout the liver. Unlike cirrhosis, which features scarring and fibrosis, NRH lacks fibrous septa between the nodules, making it a form of non-cirrhotic portal hypertension. NRH can be seen in autoimmune disorders like systemic lupus erythematosus, vascular diseases such as cystic fibrosis, viral infections and medications like azathioprine or methotrexate.

Pseudocirrhosis is a radiologic term to describe the development of diffuse hepatic nodularity caused by chemotherapy for hepatic metastasis, especially from breast cancer, pancreatic neuroendocrine, colorectal cancer. Portal hypertension can be observed in about 80% of patients with pseudocirrhosis. It is characterized by morphologic changes mimicking liver cirrhosis following chronic liver diseases. Increase in
portal flow resistance at any site within the portal venous system due to mechanical obstruction is the plausible mechanism of PH. This pathological finding often co-occurs with a spectrum of inherited renal disorders. Lastly PH is a rare complication of hepatic amyloidosis and seems to be related to reduced sinusoidal lumen and increased resistance to blood flow due to massive perisinusoidal amyloid deposits.

In preparation for surgical treatment, it is necessary to determine the side to be resected and the surgical procedure to be used. It is important to determine where to resect the bile duct, artery, and portal vein respectively. It is also necessary to properly set the predicted liver dissection plane. MDCT before biliary drainage is permissible for these decisions. This process determines the postoperative course. Identifying the number of bile ducts to be transected is also useful information during anastomosis. After this decision is made, biliary drainage are often required. In cases requiring massive hepatectomy, preoperative portal vein embolization (PE) is attempted to increase the residual liver volume. PE is expected to increase the volume of the remaining liver by about 20% (ex. L234, 280 ml → 340 ml). The residual liver volume and the results of the ICG study are combined to avoid postoperative liver failure.

Postoperatively, Ultrasonographic confirmation of hepatic arterial, portal, and venous blood flow is useful. Obstruction of hepatic arteries and impaired hepatic venous return cause rapid liver failure. Increased ascites and coagulation disorder are signs of portal vein thrombosis or infection. Continued surveillance cultures from drain effluent and bile should be performed. When bile leaks occur during hepatic resection with choledocho-jejunostomy, infection and abscesses occur very efficiently. Recovery is difficult if postoperative liver failure or DIC develops. Adequate drainage position is important to maintain leakage of choledocho-jejunostomy and bile leakage from the plane of liver dissection. Endoscopic anastomotic dilation and drainage may be beneficial.

The most important aspect of radical surgery of PHC is the process leading up to resection. Compared to hepatic resection without biliary reconstruction, careful postoperative management is required due to bile leakage and liver positional instability. Prompt judgment and treatment of any abnormalities is necessary until 2-3 weeks postoperatively, when the liver regenerates and liver function is restored.

Biliary 1. Current Surgical Management of Hilar Cholangiocarcinoma (Including Transplantation)

**Biliary 1-1**

**Aggressive surgery for advanced perihilar cholangiocarcinoma under careful preoperative preparation ~ a Japanese single-center experience in the past 15 years ~**

Dr. Yu Takahashi
Division of Hepatobiliary and Pancreatic Surgery, Cancer Institute Hospital, Japanese Foundation for Cancer Research Japan

Perihilar cholangiocarcinoma (PHCC) is a devastating disease, and the required operative resection is technically demanding and remains to be the most difficult challenge for HPB surgeons. Major hepatectomy and extrahepatic bile duct resection has been accepted as the standard procedure. A recent systematic review showed that the mortality rate was approximately 10% and liver failure was the most common reported cause of death. In some Japanese high-volume centers, trisectiomecy of the liver, combined pancreatoduodenectomy or combined vascular resection have been aggressively performed to achieve curative resection. Various preoperative preparations have been made to reduce postoperative mortality. We report here on the preoperative management and surgical outcomes of PHCC over the past 15 years, focusing on the following points:

- Preoperative Management: Biliary drainage (inside-stent) and portal vein embolization
- Hepatopancreatoduodenectomy
- Combined vascular resection
- Left trisectiomecy of the liver

Biliary 2. Liver transplantation of biliary diseases

**Biliary 2-3**

**Endoscopic Management of Biliary Complications after Living donor Liver Transplantation**

Dr. Naminatsu Takahara
Department of Gastroenterology, Graduate School of Medicine, The University of Tokyo Japan

Living donor liver transplantation (LDLT) has emerged as a crucial option for patients with end-stage liver disease. The key advantage of LDLT lies in its ability to ensure timely transplantation, resulting in a significant reduction in waiting list mortality, especially in the situation where the number of deceased donors is limited. Notable advances in surgical techniques and perioperative management have contributed to improved outcomes in LDLT, however, biliary complications remain a major unresolved issue to be addressed.

Currently, endoscopic management is a mainstay for post-LDLT biliary complications. Specifically, in cases complicated by bile leakage, endoscopic nasobiliary drainage is the preferred intervention. As for cases with anastomotic stricture, the standard strategy is balloon dilation followed by plastic stent placement, with repeat stent exchange until stricture resolution. The use of inside stents may prevent duodenobiliary reflux, and thus extending stent patency and minimizing the need for multiple stent exchange. Alternatively, recently developed covered self-expandable metallic stents with a lasso, enabling removal even after placed into the bile duct, provide an option to the multiple plastic stents placement. Furthermore, with the advent of balloon-assisted enteroscopy, it is now possible to endoscopically manage biliary complications in LDLT patients with Roux-en-Y hepaticojejunostomy.
However, these procedures are highly challenging due to the intricate nature of the biliary system in LDLT. Therefore, a comprehensive approach that integrates percutaneous and surgical interventions may be required as a salvage option when endoscopic management fails. In this study, we comprehensively investigated clinical outcomes of endoscopic management for post-LDLT biliary complications. Additionally, we discuss recent advances as well as future perspectives in this field.

**Biliary 3. Management of post operative biliary complications**

**Biliary 3-2**

**EUS Management of Bilio-Enteric Anastomotic Stricture**

**Dr. Yusuke Takasaki**

Department of gastroenterology, Juntendo University Japan

Benign biliary stricture may be a problem as a postoperative complication in surgically alter anatomy cases. In many cases, it is treated with balloon enterocopy assisted ERCP (BE-ERCP), but the endoscope may not be able to reach the anastomosis or find the bilo-enteric anastomosis. The long scopes may also limit the devices and may not provide adequate treatment. The longer treatment time of BE-ERCP is also a problem, which raises health issues not only for the patient but also for the doctor due to prolonged exposure to radiation. If stent exchange is performed frequently, radiation exposure becomes an unacceptable health problem. Percutaneous transhepatic bile duct drainage is also useful, but cosmetic problems and reduced quality of life are major problems. In addition, the long period of drainage tube placement can cause a variety of problems such as skin trouble, infection, and migration of drainage tube. In recent years, endoscopic ultrasound biliary drainage has come to be used not only for malignant biliary stricture but also for benign biliary stricture. However, the evidence for interventional EUS in benign disease is still insufficient, and there are many issues such as its indications, strategies for stenosis dilatation and treatment of concomitant bile duct stones. In this session, I will discuss bilo-enteric anastomotic stricture using endoscopic ultrasound biliary drainage, including our own approach.

**Biliary 3-3**

**Endoscopic treatment of hepaticojejunostomy anastomotic strictures with a double-balloon endoscope**

**Dr. Naminatsu Takahara**

Department of Gastroenterology, Graduate School of Medicine, The University of Tokyo Japan

Hepaticojejunostomy anastomotic stricture (HJAS) is a major complication of surgical biliary reconstruction, leading to a deterioration of quality of life as well as high morbidity and mortality. The surgically altered anatomy complicates the endoscopic approach to the hepaticojejunostomy anastomosis, making percutaneous transhepatic biliary drainage or surgical re-anastomosis the standard of care. However, with the emergence of the double-balloon endoscope (DBE), HJASs are increasingly managed endoscopically. Several clinical studies have suggested that endoscopic treatment of HJAS is technically feasible, providing a reasonably high stricture resolution rate ranging 70–100%. However, there is a paucity of data on long-term outcomes in a large-scale cohort, and predictive factors for successful endoscopic management remain unclear. Furthermore, an optimal treatment strategy for refractory cases has not yet been determined.

In this study, we aimed to evaluate clinical outcomes of DBE-assisted ERCP for HJASs and identify predictive factors for long-term treatment success.

**Biliary 3-4**

**Short- and Long-term Outcomes for Secondary hepatolithiasis: Analysis from a Nationwide Cohort Study**

**Dr. Yutaka Suzuki**

Department of Hepato-Biliary-Pancreatic Surgery, Kyorin University Hospital Japan

**Background:** Hepatolithiasis is characterized by its intractable nature and frequent recurrence. Furthermore, cholangitis, sepsis, liver abscesses, and cholangiocarcinoma frequently occur. The secondary hepatolithiasis following biliary reconstruction has been increased. In the eighth nationwide multicenter survey, 48% was secondary hepatolithiasis. Additionally, there is a noticeable rise in non-surgical treatments, particularly endoscopic interventions. The outcomes of secondary intrahepatic stone treatment, especially long-term results, remain unclear. This study evaluates secondary hepatolithiasis treatment modalities’ short- and long-term outcomes to consider appropriate management strategies.

**Methods:** The study included 128 cases of secondary hepatolithiasis registered in a nationwide cross-sectional survey conducted by the Ministry of Health, Labour and Welfare in 2017. Based on medical records, this retrospective cohort study analyzed disease backgrounds, short-term outcomes of each treatment modality, and complications, including stone recurrences, cholangitis, and cholangiocarcinoma.

**Results:** The cause of choledocho-enterostomy was congenital biliary dilatation in 34 cases (27%), followed by anomalies of the pancreaticobiliary junction in 29 cases (23%). Treatment was administered in 110 cases (86%), with 94 cases undergoing non-surgical treatment, 13 cases undergoing exclusive surgical treatment, and 3 cases receiving both non-surgical and surgical treatments. Endoscopic retrograde cholangiography by balloon endoscopy (ERC) was the most frequently performed in 77 cases. In surgical treatment, systematic hepatectomy was the most common surgical treatment in 12 cases. The residual stone rate between hepatectomy and balloon ERC showed no significant difference in residual stones (0% vs. 16%, p=0.344). There was no significant difference in stone recurrence between the two groups (5-year incidence: liver resection 28.6% vs. balloon ERC 42.3%, p=0.400). During post-treatment follow-up, bile duct strictures were observed in 47 cases (37%), and bile duct dilatation was observed in 72 cases (56%). Stricture was a significant risk factor for stone recurrence (5-year incidence: 67.3% vs. 17.8%, p<0.001) and cholangitis (5-year incidence: 56.1% vs. 10.1%, p<0.001). The bile duct dilatation was a risk factor for stone recurrence (4-year incidence: 55.7% vs. 33.3%, p=0.006) but not for cholangitis.

**Conclusion:** Minimally invasive treatment, such as endoscopy, is recommended as a first choice treatment, but a combination with other treatment modalities, including surgery, should be considered in cases where its effectiveness is insufficient. Treatment for hepatolithiasis should address complete stone removal and the management of bile duct strictures and dilatation.
Novel choledochojunostomy technique “T-shaped anastomosis” for preventing the development of postoperative cholangitis in pancreatoduodenectomy: A propensity score matching analysis

Dr. Nana Kimura
Department of Surgery and Science, Faculty of Medicine, Academic Assembly, University of Toyama Japan

Background: Cholangitis after pancreaticoduodenectomy (PD) is a serious complication that impairs quality of life including from repeated rehospitalization. However, there have been few studies of countermeasures to prevent this.

Objective: We developed a novel method of choledochojunostomy with a larger anastomotic diameter, the “T-shaped anastomosis,” whose effectiveness we examine in this study.

Methods: The study included 261 cases of PD. The T-shaped choledochojunostomy was performed with an additional incision for a distance greater than half the diameter of the bile duct at the anterior wall of the bile duct and the anterior wall of the elevated jejunum. To compensate for potential confounding biases between the standard anastomosis group (n=206) and the T-shaped anastomosis group (n=55), we performed propensity score (PS) matching. The primary endpoint was the incidence of medium-term postoperative cholangitis (within 18 months after surgery) adjusted for PS.

Results:
1) In the PS matching analysis, 54 patients in each group were matched, and the median bile duct diameter measured by preoperative CT was 8.8 mm vs. 9.3 mm, the rate of preoperative biliary drainage was 31% vs. 37%, the incidence of cholangitis within 1 month before surgery was 9% vs. 13%, and the incidence of postoperative bile leakage was 2% vs. 2%, with no significant differences.
2) The incidence of medium-term postoperative cholangitis was 14.8% vs. 3.7%, and logistic regression with PSs showed that the incidence of postoperative cholangitis was significantly lower in the T-shaped anastomosis group (odds ratio, 0.221, 95% CI 0.032-0.937; P =0.039). Multivariate analysis revealed that the T-shaped choledochojunostomy was an independent predictor of reduced incidence of cholangitis (odds ratio, 0.17, 95% CI 0.02-0.81; P =0.024).
3) In addition to 1:1 matching, a 2:1-matching, inverse-probability-of-treatment-weighting analytical method was performed as a sensitivity analysis. All analyses showed that the incidence of medium-term postoperative cholangitis was significantly lower in the T-shaped anastomosis group.

Conclusions: The T-shaped choledochojunostomy was shown to be effective with a significant reduction in the incidence of medium-term postoperative cholangitis.

Biliary 4. Tips and tricks in Endo-Hepatology with EUS
Biliary4-1

Current Status of Endo-hepatology

Dr. Yosuke Nakai
Department of Endoscopy and Endoscopic Surgery, The University of Tokyo Hospital Japan

Traditionally, the role of gastrointestinal endoscopy was limited to management of esophageal/gastric varices and portal hypertensive gastropathy. However, since the introduction of the concept of endohepatology in 2012, several procedures have been developed for endoscopic management of liver diseases. These include endoscopic ultrasound (EUS)-guided liver biopsy, liver stiffness measurement, portal pressure gradient measurement, ablation of liver tumors, and vascular interventions for conditions like gastric varices. In this presentation, the current status and a future direction of “Endo-hepatology” for liver diseases and their complications will be discussed.

Biliary 4. Tips and tricks in Endo-Hepatology with EUS
Biliary4-2

Current Status of EUS-BD

Dr. Kazuo Hara
Department of Gastroenterology, Aichi Cancer Center Japan

EUS-BD (Endoscopic Ultrasound-Guided Biliary Drainage) is rapidly becoming popular worldwide due to its usefulness. Especially notable is the advancement in endoscopic instruments, where the development and improvement of these instruments have led to increased success rates and enhanced safety of the procedure.

The indications for EUS-BD have also evolved over time. Previously, EUS-BD was indicated only for cases where ERCP (Endoscopic Retrograde Cholangiopancreatography) was unsuccessful or not feasible. However, recently, in cases where ERCP is anticipated to be challenging, Primary EUS-BD is performed without attempting ERCP. Moreover, the indications have expanded from malignant to benign conditions. In this presentation, I would like to explain, using video, the changes in indications for EUS-BD, the development of instruments, and the advancements in techniques.

Biliary 4. Tips and tricks in Endo-Hepatology with EUS
Biliary4-3

Tips & Tricks in Endo-hepatology with EUS

Dr. Sundeepl Lakhtakia
Medical Gastroenterology, Asian Institute of Gastroenterology, AIG hospitals, Hyderabad India

Endohepatology is an emerging subspecialty dealing with endoscopic diagnosis and management of liver diseases. It includes both - diagnostic endoscopic ultrasound (EUS) guided elastography, and interventional EUS guided therapy for gastric varices, EUS-guided liver biopsy and direct portal pressure measurement.

EUS guided Elastography is an exploratory diagnostic technique that evaluates tissue stiffness. Liver fibrosis alters the liver’s stiffness, making it an ideal target for elastography. EUS ‘shear wave elastography’ plays an important role in evaluating liver fibrosis. By quantifying the stiffness, EUS elastography can help in staging the degree of fibrosis. Its comparison with transcutaneous liver stiffness measurement (VCTE) using liver biopsy as gold standard showed good correlation and thus a safe and reliable alternative to VCTE. It offers advantage in obese patients, where ‘percutaneous transient elastography’ might be less effective due to the increased distance between the probe and the liver.

EUS guided Liver Biopsy (EUS-LB) has emerged as a viable alternative for acquiring liver tissue compared to traditional percutaneous and trans-jugular routes. EUS-LB is particularly useful in cases where other methods are contraindicated, such as in patients with ascites, coagulopathy, or obesity. EUS-LB offers several advantages, including decreased patient anxiety, increased satisfaction due to sedation, shorter post-procedural monitoring time, less post-procedure pain, and lower complication rates.

EUS guided Portal Pressure gradient (EUS-PPG) measurement a newer technique, is gaining attention as a potential alternative to conventional HVPG. Direct EUS-PPG involves sequential trans-gastric puncture of hepatic vein and portal vein under EUS guidance using a

**Tips and Tricks in Endo-Hepatology with EUS: Challenge and Limitations**

**Dr. Cosmas Rinaldi Aditya Lesmana**

Department of Internal Medicine, Hepatobiliary Division, Dr. Cipto Mangunkusumo National General Hospital, Medical Faculty Universitas Indonesia, Indonesia

Esophageal varices (EV) is one of the most common complications in patients with liver cirrhosis (LC). Bleeding esophageal varices (BEV) is one of the challenging conditions in clinical practice due to its high mortality rate. Esophagogastroduodenoscopy (EGD) is the standard tool for screening the presence of EV as well as managing the high-risk stigmata EV. However, the portal pressure itself, and the possible of extra-luminal EV (deep EV) has become a new challenge in patients with recurrent bleeding. Recently, endoscopic ultrasound (EUS) has been investigated to be the most promising tool not only for portal pressure evaluation, but also for a better prevention of variceal bleeding. In the need of liver disease progression evaluation, EUS has been showed to be an important tool to get liver biopsy specimen. EUS is a one stop comprehensive modality for diagnosis, treatment, and make a prognosis especially in LC patients. In patients with liver mass or small nodules which might be difficult to be detected through imaging evaluation, EUS would become a better alternative as the need of liver biopsy as well as possible local treatment, such as radiofrequency ablation (RFA) for malignant liver tumor can be performed in the same session. The limitations are to get adequate tissue sample due to its hard liver parenchyma in advance LC patients, narrowed and irregular hepatic vein for hepatic vein pressure measurement, and the tumor mass location at the right lobe of the liver which is more difficult to approach for EUS-guided RFA. Pre-procedural comprehensive evaluation is still the most important thing to do, such as coagulation issue, the presence of massive ascites, and the target location of the liver mass. Other factors such as the needle type, additional liver elastogram software, and the scope position would give a better result. In the biliary cases, EUS has been showed to have high sensitivity for gallstones, and possible malignant condition, especially for distal malignant biliary obstruction. The only limitation is to evaluate the possible hilar malignancy (intraductal cholangiocarcinoma). In this situation, intraductal ultrasound (IDUS) might be a better option for hilar or mid common bile duct lesions assessment.

Real world data of gemcitabine, cisplatin, and durvalumab combination therapy for advanced biliary tract cancer.

**Dr. Takashi Sasaki**

Department of Hepato-Biliary-Pancreatic Medicine, Cancer Institute Hospital, Japanese Foundation for Cancer Research Japan

**Background:** Drug therapy for advanced biliary tract cancer has made steady progress. In recent years, in addition to conventional chemotherapy using cytotoxic agents, molecular targeted drugs and immunotherapy have been introduced into treatment. In particular, first-line treatment with immune checkpoint inhibitors is expected to be a promising approach. Currently, the combination of gemcitabine (GEM) + cisplatin (CDDP) with durvalumab or pembrolizumab have been reported to be effective for advanced biliary tract cancer. In Japan, GEM + CDDP + durvalumab combination therapy has been in clinical use for more than a year.

**Patients and methods:** We retrospectively analyzed consecutive patients with advanced biliary tract cancer who were treated with GEM + CDDP + durvalumab combination therapy as 1st line therapy between March 2023 and October 2023 at our institution.

**Results:** A total of 42 patients were included. Median age was 67 and 25 patients (60%) were performance status 0. The primary sites were: intrahepatic cholangiocarcinoma 15, extrahepatic cholangiocarcinoma 15, gallbladder cancer 11, and ampullary carcinoma 1). Seventeen patients (40%) were recurrent case. Response rate and disease control rate were 19.0% and 81.0%, respectively. The median progression-free survival was 5.6 months. The median overall survival was not reached. Two patients were converted to surgical resection. Major grade 3/4 adverse events were neutropenia. Skin rash occurred in 8 patients (19%) and one patient experienced immune-related adverse event of adrenal insufficiency.

**Conclusions:** GEM + CDDP + durvalumab combination therapy has shown the efficacy and safety for the treatment of advanced biliary tract cancer in clinical practice.

Biliary 5. Immune and target therapy for cholangiocarcinoma

**Unveiling the Cellular Origins and Therapeutic Targets in Extrahaepatic Cholangiocarcinoma: Insights from Mouse Models and Genetic Markers**

**Dr. Hayato Nakagawa**

Department of Gastroenterology and Hepatology, Mie University Japan

The cellular origin of cholangiocarcinoma is a fascinating subject. Regarding extrahaepatic cholangiocarcinoma (ECC), there has been a focus on peribiliary glands (PBGs) as a potential stem cell niche for biliary epithelial cells (BECs), raising interest in PBGs as the cellular origin of ECC. We recently developed a new mouse model of ECC by activating Kras specifically in CK19-positive duct cells and deleting TGFβR2 and E-cadherin. In this model, BECs undergo detachment and apoptosis due to the loss of E-cadherin, leading to chronic inflammation in the bile duct. Detailed histological analysis revealed the gradual dysplasia of PBGs during inflammation, eventually progressing to cholangiocarcinoma.

To definitively establish PBG as the cellular origin of biliary tract cancer, we needed animal experiments utilizing a PBG-specific gene recombination system. Consequently, we aimed to identify PBG-specific markers and discovered that Axin2, a target gene of the Wnt/β-catenin pathway, is specifically expressed in PBGs of the periampullary region. Genetic lineage-tracing demonstrated that Axin2+ periampullary PBG...
cells function as biliary epithelial stem cells. Notably, the deletion of PTEN in periampullary PBC cells resulted in ampulla carcinoma, which was suppressed by a Wnt inhibitor. Therefore, Wnt signaling emerges as a potential therapeutic target for ampullary carcinoma. Moreover, we have established additional mouse models of extrapancreatic cholangiocarcinoma by combining different genetic abnormalities and have identified lipid metabolic reprogramming as a potential therapeutic target. In this session, I will present a portion of this data.

Biliary 5. Immune and target therapy for cholangiocarcinoma

Liquid biopsy of tumor-derived DNA in pancreaticobiliary malignancies in bile and plasma

Dr. Hiroshi Ohyama
Department of Gastroenterology, Chiba University Hospital Japan

BACKGROUND: Pancreaticobiliary cancer (PBCA) is a highly progressive disease with a poor prognosis. Obtaining sufficient pancreaticobiliary tumor tissue for genomic profiling has limitations because many PBCAs are unresectable, and only a small amount of tissue is obtained via biopsy. Liquid biopsies using plasma do not provide sufficient sensitivity. Thus, this study aimed to determine the effectiveness of liquid biopsy between bile and plasma for identifying oncogenic mutations.

RESULTS: The amount of DNA was significantly lower in plasma than in bile (P < 0.001). Oncogenic mutations were identified in 21 of 38 (55%) patients in bile and 9 (24%) in plasma samples (P = 0.005). Bile was significantly more sensitive than plasma in identifying druggable mutations (P = 0.032). Oncogenic mutations were detected in 0%, 5/11 (45%), 7/17 (41%), 9/20 (45%), 4/4 (100%), and 24/32 (75%) in unsuitable and classes I to V, respectively, with differences between classes (P = 0.012). We detected 23 drug-matched mutations in combined bile and plasma, including 5 ERBB2, 4 ATM, 3 BRAF, 3 BRCA2, 3 NFI, 2 PIK3CA, 1 BRCA1, 1 IDH1, and 1 PALB2.

CONCLUSIONS: Bile is an ideal clinical specimen in PBCA because it contains a large amount of tumor-derived DNA. Liquid biopsy using bile may be useful in searching for therapeutic agents, and the utilization of the obtained genomic information may improve the prognosis of patients with PBCA.

Biliary 6. Interventional EUS for bileary diseases

Tips and Tricks of Interventional EUS for Liver

Dr. Kazuo Hara
Department of Gastroenterology, Aichi Cancer Center Japan

The intervention for the liver using Liner EUS includes liver biopsy, liver tumor biopsy, and liver abscess drainage. Recently, EUS-FNB (Fine Needle Biopsy) from liver tumors has been increasingly performed to collect tumor specimens for cancer genomic medicine. In particular, tumors in the liver S1 region, located deep in the body, are difficult to access percutaneously, making EUS-FNB useful. The use of EUS enables simultaneous liver tumor biopsy, biopsy of enlarged lymph nodes, and ascites collection, offering greater utility than percutaneous biopsy. Understanding the EUS anatomy of the liver is necessary to visualize the targeted liver area. The trick to visualize the liver area is to focus on the vessel.

Biliary 6. Interventional EUS for bileary diseases

Terminology and Classification in Interventional-EUS

Dr. Hiroyuki Isayama
Department of Gastroenterology, Graduate School of Medicine, Juntendo University Japan

Development of Interventional EUS (I-EUS) is rapidly, and new procedures, indications and devices are reported day by day. There are no standard rules in the words which used in published numerous reports, and confusions are arising. The authors had published “Clinical practice guidelines for safe performance of endoscopic ultrasound/ultrasound-guided biliary drainage: 2018” in 2019, and confused in terminology of I-EUS. Then, Japan Gastroenterological Endoscopy Society (JGES) decided to make “Subcommittees for Terminology of Interventional EUS” (Chair: Isayama H). In this lecture, the progress of this activity and decided terminology and classifications of I-EUS will be told. From our discussion, I-EUS are classified into 5 categories; 1) EUS-sampling, 2) EUS-guided through-the-needle examination (EUS-TTNE), 3) EUS-guided drainage/anastomosis (EUS-D/A), 4) Trans-endosonographically/guided created route (Trans-ESCR), 5) EUS-guided delivery. 1) EUS-sampling is including tissue acquisition (EUS-TA) and fluid sampling, and can use EUS-FNA as well. 2) EUS- TTNE is the diagnostic procedures through the punctured needle; imaging, measurement and biopsy (TTNB) using miniature devices can through the needle cavity. 3) EUS-D/A is drainage procedures for organs and fluid collections. EUS-D/A for the organs (bile duct, pancreatic duct, gallbladder, digestive tract, etc.) is drainage procedure but anastomosis simultaneously, then use “ -stomy” (EUS-guided hepaticogastroenterology, EUS-guided pancreategastrostomy). However, fluid collection is disappeared after drainage, then only words of drainage is available (transgastric EUS-PFD for WON). 4) ESCR is proposed new word represents a general term of EUS-guided/endosonographically created route. Endoscopic necrosectomy is performed through the matured route after EUS-guided drainage of walled off necrosis. Other trans ESCR procedures are antegrade stenting or stone management through the anastomosis. 5) EUS-guided delivery is the procedure to deliver the liquid, drug, equipment, energy, etc. after the puncture. Tumor ablation therapy, neurolysis implantation of fiducial markers are included. In this proposal, there were some newly created words. T-DAS is “transluminal drainage/anastomosis stent” including plastic and metallic stent, and lumen apposing metal stent is representative. The aim of T-DAS is keeping the ESCR differ from the conventional stent which keep the luminal patency at the stricture. Many doctors are using “fistula” for created route in EUS-D/A, however, “Fistula” is originally means accidentally created unusual route which are harmful, inconvenient and should be closed. Then, we proposed “anastomosis” and “route” in EUS-D/A and “ESCR” as a general term. We believed newly proposed terminology and classifications are useful to categorize various and brad-new procedures.
Interventional EUS for Biliary Diseases

Dr. Jae Hee Cho
Yonsei University College of Medicine, Gangnam Severance Hospital Korea

The integration of interventional Endoscopic Ultrasound (iEUS) into routine clinical practice has significantly bridged a critical gap in managing biliary diseases, notably aiding patients with complex anatomical challenges or those at high risk from conventional surgical or endoscopic procedures. Its minimally invasive nature, coupled with the capability for direct visualization and intervention, has established iEUS as a vital tool in pancreatobiliary disease management. EUS-guided biliary drainage (EUS-BD) offers a straightforward technique for bile duct drainage, whereas EUS-guided gallbladder drainage (EUS-GBD) provides a minimally invasive solution for high-risk surgical patients with acute cholecystitis, achieving high success rates with minimal adverse events.

Regarding the long-term outcomes of EUS-BD, a Korean retrospective study analyzed the clinical outcomes of EUS-guided choledochoduodenostomy (EUS-CDS) and hepaticogastrostomy (EUS-HGS) for treating distal malignant biliary obstruction (MBO). The study included 116 patients, divided into EUS-CDS (n=56) and EUS-HGS (n=60) groups. Both groups exhibited high technical success rates—98.2% for EUS-CDS and 96.7% for EUS-HGS. Clinical success was also significant, at 96.4% for EUS-CDS and 88.3% for EUS-HGS. The EUS-CDS group showed a significantly longer average stent patency of 770.3 days compared to 165.5 days for the EUS-HGS group. The only independent risk factor for stent dysfunction identified was systemic treatment following EUS-guided biliary drainage. The incidence of stent dysfunction was higher in the EUS-HGS group compared to the EUS-CDS group, with no significant differences in late adverse events. This study highlights the efficacy and safety of interventional EUS techniques in managing distal MBO, particularly emphasizing the superior stent patency associated with EUS-CDS.

In addition, a recent meta-analysis compared the efficacy and safety of EUS-GBD with percutaneous gallbladder drainage (PTGBD) in patients with acute cholecystitis. The analysis included four studies with a total of 535 patients. Although PTGBD showed a slightly higher technical success, EUS-GBD was associated with fewer adverse events, reduced unplanned readmissions, and a lower need for reinterventions, indicating its potential as a safer and more effective alternative to PTGBD, especially for patients at high surgical risk. The adoption of iEUS has not only enhanced the safety and efficacy of treating pancreatobiliary diseases but also significantly improved patient comfort and recovery times. As technology and expertise in this field continue to evolve, iEUS is poised to play an increasingly central role in a multidisciplinary approach, promising even better patient outcomes and broader applications in gastroenterology.
pediatric patients because only ALP is incorporated in the evaluation of increased biliary enzyme. Secondly, small duct PSC cannot be diagnosed. Thirdly, PSC recurrence following liver transplantation cannot also be diagnosed. New findings and knowledge have accumulated after the proposal of PSC2016. The Intractable Hepato-Biliary Diseases Study Group of the Committee of Research on Measures for Intractable Diseases in Japan established a working group consisting of researchers specializing in PSC. The working group develops tentative revised diagnostic criteria for PSC to overcome these limitations of PSC2016. Revised criteria also consist of four items. They are 1) biliary finding, 2) association with inflammatory bowel disease, 3) increased biliary enzyme, and 4) liver histology. Revisions are as follows; 1) Cholangiographic finding is revised to biliary finding to use other modalities (EUS, IDUS, POCUS) in addition to ERC/MRCP. 2) Gamma-glutamyl transpeptidase is incorporated in addition to ALP for the evaluation of elevated biliary enzyme. 3) Diagnostic criteria for PSC recurrence following liver transplantation are added. The working group is going to propose the revised diagnostic criteria for PSC after the discussion and public hearing.

Anti-Integrin αvβ6 Autoantibodies in Patients with Primary Sclerosing Cholangitis

Dr. Masahiro Shiokawa

Department of Gastroenterology and Hepatology, Kyoto University Graduate School of Medicine Japan

Patients with primary sclerosing cholangitis (PSC) possess autoantibodies against biliary epithelial cells. However, the target molecules remain unknown. In addition, although diffuse biliary stricture is the most important finding for diagnosing with primary sclerosing cholangitis (PSC), some cases have potential to be misdiagnosed with other biliary diseases. Therefore, the development of specific diagnostic markers for PSC is needed.

We recently found that PSC patients possessed anti-integrin αvβ6 autoantibodies. By enzyme-linked immunosorbent assays (ELISA), anti-integrin αvβ6 antibodies were detected in 49/55 (89.1%) patients with PSC and 5/150 (3.3%) controls (P < 0.001), with a sensitivity and specificity of 89.1% and 96.7%, respectively, for PSC diagnosis. When focusing on the presence or absence of IBD, the proportion of the positive antibodies in PSC with IBD was 97.2% (35/36) and that in PSC alone was 73.7% (14/19) (P = 0.008). Integrin αvβ6 was expressed in bile duct epithelial cells. Immunoglobulin (Ig)G from 15/33 patients with PSC blocked integrin αvβ6-fibronectin binding through an RGD (Arg-Gly-Asp) tripeptide motif.

In conclusion, autoantibodies against integrin αvβ6 were detected in most patients with PSC; anti-integrin αvβ6 antibody may serve as a potential diagnostic biomarker for PSC.

We proceeded studies further. Our study above was conducted on patients from only two institutions. Therefore, a validation research in multi-centers is needed to eliminate selection bias. In addition, the study was examined using our conventional in-house enzyme-linked immuno-sorbent assay (ELISA) method. To compare the data from different facilities, development of a universal kit for the antibody measurement is needed.

The Intractable Hepato-Biliary Diseases Study Group in Japan has conducted the nation-wide PSC registry study “Establishment of disease registry of primary sclerosing cholangitis for investigation of clinical features, natural history, and prognostic factors” to prospectively register clinical information and sera of patients with PSC in Japan. Using these serum samples and clinical information, we examined diagnostic value of anti-integrin αvβ6 autoantibody for PSC as a Japanese nation-wide validation study.

In addition, we collaborated with Medical and Biological Laboratories CO., LTD. to establish Anti-Integrin αvβ6 ELISA Kit which enables easier detection of the anti-integrin αvβ6 antibodies. The use of monoclonal antibody for integrin αvβ6 with known concentration facilitated the standardization of anti-integrin αvβ6 autoantibody titers. I will show these results in this section.

Endoscopic Treatment in PSC

Dr. Cosmas Rinaldi Adithya Lesmana

Department of Internal Medicine, Hepatobiliary Division, Dr. Cipto Mangunkusumo National General Hospital, Medical Faculty Universitas Indonesia, Indonesia

Primary sclerosing cholangitis (PSC) is a challenging clinical condition which is required a good and proper diagnosis before deciding the best strategy approach as it can lead to malignancy condition. Liver transplantation is still the best treatment for PSC; however, regular endoscopic approach is the most routine procedure in daily practice. Despite the imaging innovation, such as magnetic resonance cholangiopancreatography (MRCP), other innovations in endoscopy, such as transpapillary biopsy, fluorescence in-situ hybridization (FISH) method from the brush material, intraductal biopsy using innovation and dedicated cholangioscope have increased the diagnostic value, especially for cholangiocarcinoma (CCA) early detection. Biliary stenting through endoscopic retrograde cholangiopancreatography (ERCP) procedure is the main procedure in daily practice for PSC management. Endoscopic luminal radiofrequency ablation (ELRA) is one of innovation treatment for biliary stricture, especially to maintain biliary stent patency in intraductal CCA.

Recent advances in medical treatment for PSC

Dr. Suguru Mizuno

Department of Gastroenterology & Hepatology, Saitama Medical University Japan

Primary sclerosing cholangitis (PSC) is a disease characterized by fibrotic strictures of intra- and extrahepatic bile ducts, leading to liver cirrhosis due to bile stasis. While its pathogenesis involves presumed autoimmune mechanisms, it remains incompletely understood. At present, liver transplantation stands as the sole definitive treatment, but opportunities for deceased donor liver transplantation are limited, and living donor liver transplantation pose significant challenges. Additionally, graft failure due to a high recurrence rate after transplantation remains a concern. Though no established pharmacological treatment exists, various studies are underway with promising outcomes expected.
Ursodeoxycholic acid (UDCA) represents the most extensively studied pharmacotherapy, demonstrating reduction in hepatic and biliary enzymes in numerous randomized controlled trials. However, due to reported increased mortality and liver transplantation at high doses, it is not considered standard therapy in various national guidelines. Nonetheless, recent reports associating decreased serum ALP levels with prognosis have renewed interest in the potential of UDCA to improve outcomes. Retrospective analyses using nationwide surveys in Japan have reported improved transplantation-free survival rates associated with UDCA therapy. Bezafibrate, a medication for dyslipidemia, acts as an agonist for Peroxisome Proliferator-Activated Receptor alpha (PPARα) and has been reported to decrease hepatic and biliary enzymes in PSC. However, its evidence remains limited to a few cases, lacking established confirmation.

Other pharmacotherapies include a Phase II randomized trial showcasing improvement in hepatic and biliary enzymes with cilofexor, a farnesoid X (FXR) receptor ligand, followed by an ongoing Phase III trial. Recent advances reveal the involvement of the gut microbiota in PSC pathogenesis, driving research toward pathophysiology-based treatments. Reduced diversity in the gut microbiota of PSC patients has been reported, with expectations that restoring diversity through fecal microbiota transplantation may lead to therapeutic benefits. Moreover, Klebsiella pneumoniae is frequently detected in the intestines of PSC patients, prompting investigations into its role in causing liver inflammation via bacterial translocation. Studies on bacteriophage therapy targeting K. pneumoniae are also underway.

Progress in understanding PSC's pathophysiology fuels optimism for further advancements in treatment-related research in the foreseeable future.

**The revised TOKYO criteria for hilar biliary obstruction**

**Dr. Tsuoshi Hamada**

Department of Gastroenterology, Graduate School of Medicine, The University of Tokyo Japan

The consensus-based TOKYO criteria were introduced as a standardized reporting system to address the inconsistent documentation of outcomes of endoscopic transpapillary biliary drainage. The main aim was to solve issues arising from heterogeneous reporting practices across different studies, which hindered the comparability and interpretation of stent outcomes. However, the original TOKYO criteria were less applicable to recent endoscopic biliary drainage modalities such as those based on endoscopic ultrasound or balloon endoscopy. As opportunities for managing hilar biliary obstruction and benign biliary strictures through endoscopic drainage have expanded, and biliary ablation has been introduced for both benign and malignant strictures, there is a growing need to revise the criteria. Additionally, with cancer patients experiencing prolonged survival times, there is an increased focus on evaluating overall outcomes throughout the period of endoscopic biliary drainage rather than solely concentrating on the initial stent patency.

Acknowledging these gaps, a committee within the Japan Gastroenterological Endoscopy Society has been formed to revise the TOKYO criteria to align with current clinical practices in endoscopic biliary drainage. The revised criteria propose standardized reporting items applicable to endoscopic biliary drainage as a whole, along with specific items tailored to different conditions and interventions. The term "stent-demanding time" has been introduced to encompass the entire duration of endoscopic biliary drainage, providing a comprehensive evaluation of overall stent-related outcomes. The adoption of these revised TOKYO criteria is expected to facilitate the design and reporting of clinical studies, offering a goal-oriented approach to assessing endoscopic biliary drainage.

The revised TOKYO criteria aim to evaluate the following conditions and interventions: distal biliary obstruction, hilar biliary obstruction, EUS-guided biliary drainage, biliary drainage via balloon-assisted endoscopy, benign biliary strictures, scheduled exchange of a plastic stent, biliary ablation. In this presentation, I will focus on the part of assessing endoscopic biliary drainage for hilar biliary obstruction.

**Biliary 8. Endoscopic management of hilar obstruction**

**Biliary 8-3**

**Endoscopic Management of Hilar Obstruction**

**Dr. Jae Hee Cho**

Yonsei University College of Medicine, Gangnam Severance Hospital Korea

Hilar cholangiocarcinoma (hilar CC), a rare but prevalent form of bile duct cancer, poses significant treatment challenges due to its advanced stage at diagnosis and the historical lack of effective treatments, resulting in poor survival rates. The primary treatment approach involves surgical resection, targeting both intra- and extrahepatic bile ducts and the affected liver lobe. Preoperative biliary decompression is crucial for patients presenting with obstructive jaundice, a common symptom of hilar CC, and scheduled for major liver surgery. Traditionally, percutaneous transhepatic biliary drainage (PTBD) has been preferred, especially in cases with additional complications such as cholangitis, malnutrition, or liver dysfunction. More recently, endoscopic methods like endoscopic nasobiliary drainage (ENBD) have become popular due to their diagnostic benefits in evaluating bile volume and characteristics. Despite its advantages, ENBD can cause bile leak and patient's discomfort, leading some clinicians to opt for endoscopic biliary stenting (EBS). However, EBS may carry a higher risk of obstructive cholangitis and postoperative issues, making ENBD the recommended first-line treatment, although EBS may still be used if it provides sufficient drainage.

In cases of inoperable hilar CC, the optimal method for liver drainage is still debated. Generally, draining more than 50% of the liver volume is advised, but the choice between plastic stents (PS) and uncovered self-expandable metal stents (uSEMS) is controversial. PS are often selected for their ease of replacement and removal, while uSEMS are preferred for their durability and longer patency. The decision between unilateral and bilateral stenting also varies, with some evidence suggesting that bilateral stenting might offer longer stent patency. Another therapeutic consideration is intrahepatic radiofrequency ablation (ID-RFA), which shows promise for treating unresectable malignant biliary obstructions. However, due to the perihilar bile duct's proximity to critical vascular structures, the risk of ID-RFA-related complications may be elevated. Our research suggests using the shortest available ID-RFA probe to minimize these risks, based on findings from animal studies that showed increased bile duct perforation risk with standard ID-RFA settings.

In summary, the management of hilar CC, including preoperative and palliative biliary decompression, requires a tailored approach that considers the complexities of each case. A multidisciplinary team's expertise is crucial in determining the most appropriate treatment strategy, whether it involves surgical resection, biliary decompression, or advanced therapies like ID-RFA. Despite the advancements, a consensus on the best practices for hilar CC is still needed, underscoring the importance of individualized treatment plans supported by collaborative decision-making.
Biliary 8. Endoscopic management of hilar obstruction

Suprapapillary placement of plastic stents for unresectable malignant biliary hilar obstructions

Dr. Yoshihide Kanno
Department of Gastroenterology, Sendai City Medical Center Japan

Unresectable malignant obstructions of the biliary hilum represent a significant challenge in the field of palliative pancreatobiliary endoscopy. Prior meta-analyses have favored uncovered metal stents due to their prolonged patency compared to plastic stents placed across the papilla. However, advancements in cancer treatment have rendered the uncovered design problematic because it cannot be removed. Once the metal stent becomes occluded, it induces idioopathic cholangitis which interrupts cancer therapies, reduces quality of life, and requires extremely complicated treatments since it cannot be removed. Plastic stents, alternatively, offer reversibility, simplifying re-interventions, despite their shorter function periods when placed across the papilla. Recently, the focus has shifted to suprapapillary placement, which has been proven to be feasible in recent studies. Retrospective or single-arm studies have reported median patency periods of suprapapillary plastic stents from 99 to 190 days, making this approach a viable option.

In our multicenter, randomized control trial comparing suprapapillary-externally placed plastic and metal stents, we found no significant differences in the technical success, clinical success and adverse events between the groups. While plastic stents exhibited a tendency for shorter function periods compared to metal stents without statistical significance (250 vs. 361 days, p = 0.34), both are potential initial permanent drainage options. While plastic stents, alternatively, offer reversibility, simplifying re-interventions, despite their shorter function periods when placed across the papilla, we found no significant differences in the technical success, clinical success and adverse events between the groups. While plastic stents exhibited a tendency for shorter function periods compared to metal stents without statistical significance (250 vs. 361 days, p = 0.34), both are potential initial permanent drainage options, considering the removability of plastic stents.

Hepatitis A and E viruses: recent advances in research and clinical practice recommendations

Dr. Tatsuo Kanda
Division of Gastroenterology and Hepatology, Nihon University School of Medicine Japan

In 2018, there was an outbreak of hepatitis A virus (HAV) infection in Japan, and hepatitis A is also considered a sexually transmitted disease. Patients with hepatitis A should be receiving attention, and this disease needs to be prevented more than ever. Despite the development of an effective vaccine against hepatitis A, universal vaccination has not yet been performed in Japan. In Japan, until the early 2000s, acute hepatitis E virus (HEV) infection was considered rare until reports emerged confirming the existence of HEV genotype 3 and 4 infections. Until now, vaccines against hepatitis E have not yet become available in Japan. The Japanese National Health Insurance System does not approve anti-HAV and anti-HEV drugs.

Recently, we discovered several effective drugs against HAV infection and their mechanism by drug repositioning, in silico screening (Sasaki-Tanaka R, et al. J Virol. 2022 Sep 28; Sasaki-Tanaka R, et al. J Virol. 2023 Feb 28; Sasaki-Tanaka R, et al. Int J Mol Sci. 2023 Jun 3; Int J Mol Sci. 2022 May), etc. Although the use of off-label ribavirin for HEV infection was shown to be effective, the development of antivirals against HAV and HEV infection is urgently required. The Japan Agency for Medical Research and Development (AMED) Hepatitis A and E viruses (HAV and HEV) Study Group has recently published the recent advances in research and clinical practice recommendations for hepatitis A. Here, the recent advances in research and clinical practice recommendations for HAV and HEV infections in Japan will be presented.

Management of Hepatic Encephalopathy with Special Reference to Combination Therapy

Dr. Barjesh Chander Sharma
Gastroenterology, GIPMER India

Hepatic encephalopathy (HE) is characterized by wide spectrum of neurological and psychiatric alterations resulting due to advanced liver malfunction. It is a neurological ailment related to hepatic insufficiency and/or portosystemic shunts. Its clinical features include neuropsychiatric dysfunction, ranges from subclinical changes to coma. Overt HE is found in 30–45% of patients with cirrhosis and 10–50% of patients with a transjugular intrahepatic portosystemic shunt (TIPS). Recurrence of HE is seen in 47-57% of patients by the end of one year despite being on treatment. Occurrence of each bout of HE results in increased morbidity, hospitalization, health care burden, poor prognosis and increased mortality. Combination of rifaximin with lactulose has favourable effect on patients with recurrent HE who have recurrent bouts of HE despite on lactulose. Thus, rifaximin along with lactulose should be considered for preventing the recurrent episodes of HE. With use of rifaximin as addition to lactulose for the prophylaxis of third and further episodes of HE, cost can be saved both from a hospital and healthcare payer’s perspective. From healthcare payer’s view, costs raise by adding rifaximin to lactulose is reduced due to improved survival with rifaximin causing relatively low drug and liver transplant related costs. Combination of lactulose plus albumin is also more effective than lactulose alone in the management of overt HE with more decrease in the levels of arterial ammonia, interleukin-6, interleukin-18, tumor necrosis factor-alpha, and endotoxins. Triple combination of L-ornithine L aspartate (LOLA) with lactulose and rifaximin is more efficacious than only lactulose and rifaximin in improving grades of HE, recovery time from HE and with reduced 28-days mortality. In cirrhotic patients with advanced HE adjuvant treatment with LOLA along with lactulose and metronidazole is safe and associated with fast improvement and reduced hospital stay. In conclusion combination therapy including lactulose, rifaximin, albumin and LOLA is effective in the management and prevention of recurrent HE.

Hepatitis B Foundation USA

Hepatitis D virus (HDV) is an RNA “sub-virus” that infects patients with co-existing hepatitis B virus (HBV) infections. HDV burden is estimated to be approximately 15-20 million people worldwide. Despite HDV severity, screening for the HDV remains inadequate. HDV screening would benefit from a revamped approach that automatically reflexes testing when individuals are diagnosed with HBV if HBsAg+, to anti-HDV total and then to quantitative HDV-RNA polymerase chain reaction (PCR) rather than only testing those at high risk sequentially. There are no current treatments in the United States (US) that
are Food and Drug Administration (FDA)-approved for the treatment of HDV; and one approved therapy in the EU by the EMEA with conditional approval; however, bulevirtide and is under review with the US FDA. Current treatment strategies in many countries are centered on the use of pegylated interferon alfa-2a (PEG-IFNa-2a). There are other therapies in development globally that have shown promise, including lonafarnib (LNF) and the NAP: REP 2139. LNF has shown substantial response in the LOWR trials, but trials halted due to some liver toxicity risk. BLV is a well-tolerated drug, but it is not finite therapy and has shown significant on-treatment HDV RNA responses in the multiple MYR clinical trials, and the FDA cited concerns with the manufacturing and patient preparation of the drug that have delayed approval. The PDUFA date for BLV in the US is mid-2024. Current studies with both BLV and LNF are limited in providing sustained virological response (SVR); future trials will need to demonstrate more substantial SVR with possible triple combination trials as options. REP 2139 is in compassionate use trials in the EU region. In summary, HDV/HBV is a very high-risk viral infection and justifies a test all approach and a treat all approach who are HDV RNA+. Interferon remains a global tool for HDV treatment with response rates in the 20% range with newer therapies in evolution.

Others 3. Coinfection of Viral Hepatitis and HIV

Other3-2

Clinical features and vaccine efficacy of hepatitis A virus infection in HIV infection

Dr. Takeya Tsutsumi

Department of Infection Control and Prevention, Department of Infectious Diseases, Faculty of Medicine The University of Tokyo Japan

In 2018, there was an outbreak of hepatitis A virus (HAV) infection in Japan, following outbreaks in foreign countries such as European countries, United States, and Taiwan. Most of infected patients were men who have sex with men (MSM) including human immunodeficiency virus (HIV)-infected patients. HAV is usually transmitted through fecal-oral infection, and the outbreak was probably spread by unique sexual activities of MSM. A similar HAV outbreak was observed among MSM in Japan around 2000. About 20 years passed, and the treatment strategy for HIV infection has been developed, leading to better immunological condition of people living with HIV (PLWH). Accordingly, the clinical presentation of HAV infection in PLWH was different from the previous outbreak.

To prevent HAV infection, HAV vaccine is generally useful. Centers for Disease Control and Prevention (CDC) recommends HAV vaccine for MSM as well as people traveling to endemic countries. However, the efficacy of HAV vaccine to obtain enough anti-HA IgG antibody (anti-HA-IgG) has been shown to be lower among PLWH compared to non-HIV-infected people. It is known that even PLWH who have a good HIV control sometimes cannot respond to other vaccines. Furthermore, compared to healthy people, PLWH have difficulty maintaining sufficient titers of anti-HA-IgG to prevent HAV infection. As mentioned above, the clinical characteristics of HAV infection in PLWH, including my own experience, will be introduced

Dr. Aleksander Krag

Department of Gastroenterology and Hepatology University of Southern Denmark & Odense University Hospital Denmark

Steatotic Liver Disease (SLD), formerly known as fatty liver disease, encompasses a range of liver conditions with fat accumulation in the liver. However, the role of alcohol in the progression and exacerbation of SLD is significant and multi-faceted. Alcohol consumption, particularly chronic and heavy use, directly contributes to the development of Alcohol-Related Liver Disease (ArLD), a subset of SLD. ArLD progresses from simple steatosis (fatty liver) to more severe forms like alcoholic hepatitis, fibrosis, and cirrhosis. The liver, responsible for metabolizing alcohol, undergoes oxidative stress and inflammation due to the toxic metabolites produced during this process. This stress damages liver cells, leading to fat accumulation, inflammation, and eventually scarring. The interplay between alcohol and other risk factors for SLD, such as obesity, metabolic syndrome, and diabetes, can accelerate liver damage. These risk factors are synergistic. Alcohol exacerbates insulin resistance, a key component of metabolic syndrome, which in turn contributes to the progression of Metabolic dysfunction Associated Steatotic Liver Disease (MASLD), another form of SLD. Furthermore, alcohol can influence gut microbiota, affecting metabolic functions and promoting liver inflammation.

The threshold of alcohol consumption that leads to ArLD varies among individuals, influenced by genetic factors, gender, overall health, and concurrent metabolic conditions. This variability complicates the management and prevention strategies for SLD. Biomarkers play a crucial role in diagnosing and managing Alcohol-Related Liver Disease (ArLD). They enable early detection of liver damage, monitor disease progression, and assess the response to treatment.

Management of SLD, particularly ArLD, involves lifestyle interventions with a focus on reducing alcohol intake. Complete abstinence is often recommended for individuals with ArLD, as even moderate alcohol consumption can aggravate liver damage. Moreover, addressing other metabolic risk factors, such as obesity and diabetes, is crucial in managing SLD.

Can Blood-Based Biomarker HCC Surveillance Replace Ultrasound?

Dr. Tawesak Tanwandee

Department of Medicine Faculty of Medicine Siriraj Hospital, Mahidol University Thailand

Hepatocellular carcinoma (HCC), a leading cause of cancer mortality globally, especially in Asia, often presents at advanced stages with limited therapeutic options. Current surveillance standards recommend ultrasound in conjunction with alpha-fetoprotein, yet the effectiveness of ultrasound is notably reduced in patients with advanced cirrhosis or obesity, and is subject to radiologist interpretative variability. Advances in HCC screening, such as short protocol CT or MRI, demand complex equipment and experienced radiologists.

Recent studies have explored multi-biomarker blood tests (mt-HBT) for HCC surveillance, especially in compensated cirrhosis patients. These include biomarkers like AFP-L3, PIVKAII, and algorithms such as GALAD, GAAD, and ASAP score. Risk-based surveillance approaches have also been investigated for enhanced cost-effectiveness. Additionally, emerging research on cell-free DNA-based tests shows higher specificity for HCC. This body of evidence suggests that mt-HBT significantly outperforms ultrasound in early-stage HCC detection. Hypothetical models indicating improved adherence to blood-based biomarkers further underscore their potential advantages.
These findings could revolutionize HCC surveillance protocols, enhancing detection efficiency and potentially improving long-term patient outcomes. However, current studies have not extensively examined implementation in real-world settings, leaving questions about potential false positives and negatives unaddressed.

In conclusion, while blood-based HCC surveillance appears promising, offering increased sensitivity and reduced interpretative bias, its efficacy in replacing ultrasound as the standard practice requires further validation in real-world applications.

APASL initiative to reshape the discipline of Hepatology in Asian-Pacific region beyond 2024

Dr. George Lau

Humanity and Health Clinical Trial Center, Humanity and Health Medical Group, Hong Kong SAR, China

Till 2023, liver diseases remain a major health threat in Asian-Pacific region, accounting for two-third of the global deaths due to acute-on-chronic liver failure, end-stage liver cirrhosis and hepatocellular carcinoma. The major aetiology of liver diseases are chronic hepatitis B and C, metabolic dysfunction-associated (MAFLD) and alcoholic fatty liver disease (AFLD). Asian-Pacific Association for the Study of Liver (APASL) is the premier Asian-Pacific liver society set up in 1978 aiming to create and to disseminate the best evidence-based clinical knowledge to relieve patients’ suffering from liver diseases. Sharing the same vision, APASL is in alliance with European Association for the Study of the Liver (EASL), American Association for the Study of Liver Diseases (AASLD) and Latin American Association for the study of the liver (ALEH). In the past few decades, there have been rapid advancement and availability of laboratory, imaging diagnostic and endoscopic technology, more stringent and transparent conduct of clinical trials, development of sophisticated computation and big data collection (with artificial intelligence-AI) and change in social-economic environment. Very importantly, machine learning (ML) and AI algorithms can help to address data integrity by ensuring consistency and reliability across various data sources and over time. In the age of AI, where machine learning models continuously learn and evolve, maintaining data integrity is not just a one-time effort; it’s an ongoing discipline that requires robust strategies and advanced technological support. New drug development is anticipated to be supercharged with AI. With the digitalisation of medical data, more personalised medical care can be provided to our patients, especially those living in resource-limited areas. With AI-assisted robotics, medical procedures can also be more effectively and safely performed. Skills and knowledge are also necessary to perform ultrasound-based examination for liver and how to read CT-based or MRI-based imaging data. Basic sciences related to laboratory techniques used to provide clinical data should be understood. The application of AI to guide screening, diagnosis and treatment of patients with liver diseases should be enhanced. Therefore, it is now time to reshape the discipline of hepatology to update knowledge and skills which will allow us to advance our clinical management to our patients. Finally, it is of great importance to integrate the art of humanities into medical practise to reshape and modernise professional hepatology discipline with emphasize on empathy, communication, and teamwork.

State-of-the Art Lecture

AI research for clinical application: from research planning to regulatory approval

Dr. Ryuji Hamamoto

National Cancer Center Research Institute Japan

Expectations for artificial intelligence (AI) have been rising in recent years due to advances in machine learning technology, particularly deep learning, the emergence of inexpensive, high-performance GPUs (Graphics Processing Units), and the expansion of public databases as the Big Data era begins, making it easier to utilize large data sets. In the long history of AI research, however, it has not been smooth sailing. There have been periods of high expectations for AI, known as the “AI boom,” and then a period of “AI winter,” when AI failed to technologically meet those high expectations, leading to widespread disappointment in AI. On the other hand, an important aspect of the third AI boom, which began with the advent of deep learning, is that social implementation is progressing. AI is now being utilized in a wide range of fields, such as face recognition for airport security, automatic translation, automatic voice recognition, and home appliances. The medical field is no exception, and the development of SaMDs (software as medical devices) utilizing AI is underway around the world, and many products have been approved as medical devices and are being used in clinical practice. In 2016, we launched the project “Development of an Integrated Cancer Medical System Using Artificial Intelligence” as a JST CREST research project, and have been working on various medical AI research and development projects. As a result, our AI-based endoscopy diagnosis support software was approved as a medical device in Japan in 2020, and later confirmed to the CE Mark in Europe, and is already in clinical use in Japan and Europe. In addition to AI-based endoscopy-assistive software, the company has also published a variety of other medical AI-related results that have led to clinical applications. In this presentation, I will introduce the current status and future possibilities of medical AI based on our experience in promoting the entire process from research planning to actual clinical application.

Role of liver resection in the era of advanced systemic therapy for hepatocellular carcinoma

Dr. Norihiro Kokudo

National Center for Global Health and Medicine Japan

The recent dramatic progress in systemic therapy for hepatocellular carcinoma (HCC) provides the possibility of a combination of surgery and systemic therapy including adjuvant, neoadjuvant, or conversion settings. After the turn of the century, there have been at least three negative studies testing adjuvant therapies after curative resection or ablation, including Uracil-Tegafur an oral chemotherapeutic drug, sorafenib, and peretinoin, a synthetic retinoid that may induce apoptosis and differentiation of liver cancer cells. Using more potent immunotherapy (ICIs), there are at least 4 phase-III trials ongoing for adjuvant immunotherapy: Nivolumab, Durvalumab/Bevacizumab, Pembrolizumab, and Atezolizumab+Bevacizumab. Very recently, the last one showed significantly better RFS for adjuvant Atezolizumab+Bevacizumab. Another promising combination of surgery and systemic therapy is neoadjuvant therapy for potentially resectable cases or conversion strategy for oncologically unresectable cases. There have been 2 neoadjuvant trials for technically or oncologically unresectable HCCs ongoing in Japan: LENS-HCC trial using Lenvatinib and RACB study using Atezolizumab+Bevacizumab. Although we may need longer follow-up, OS in resected cases seems...
much higher than that for unresectable cases. Recently, Japan Liver Cancer Association (JLCA) and the Japanese Society of HPB Surgery (JSHPBS) created a joint working group on “so-called borderline resectable HCC.” They compiled a Japanese consensus on this issue and it has been published on the websites of JLCA and JSHPBS. The definition of resectability or borderline resectability provides the common language on advanced HCC for investigators and it is a useful tool for future clinical trials.

Basic and Clinical Research of Cholangiocellular Carcinoma

BCR1-1

Role of pathology in terms of Basic and Clinical Research of Cholangiocellular Carcinoma

Dr. Mina Komuta
Pathology department, International University of Health and Welfare, School of Medicine, Narita Hospital Japan

Cholangiocarcinoma (CCA) harbours actionable mutations in 50% of cases, offering promising treatment options. However, CCA is a heterogeneous tumour driven by the diversity of cholangiocytes, primarily dictated by the size of the bile duct (BD), complicating tumour characterization. Cholangiocytes, lining the epithelia of the biliary tree, exhibit distinct phenotypes based on BD size: cuboidal-shaped cholangiocytes line the small BD without apparent mucin production, while cylindrical cholangiocytes with mucin production cover the large BD. Intrahepatic CCA (iCCA) is categorized into two subgroups: the large and small BD types. As cancer maintains the phenotype of its cell of origin, both iCCA subtypes display disparate features in terms of clinical, pathological, and genetic characteristics. Accounting for these differences is crucial in research endeavours. Additionally, the large duct type of iCCA shares clinical, pathological, and molecular features with extrahepatic CCA (eCCA). This is because both CCA originate from the similar cell of origin which are mucin-producing cylindrical cholangiocytes in the intra-, and the extrahepatic BD. In contrast, the small duct type of iCCA exhibits tumour heterogeneity, posing challenges in distinguishing it from other primary liver cancers such as hepatocellular carcinoma (HCC) and combined HCC-CCA, particularly in certain circumstances. This heterogeneity is particularly relevant for characterizing perihilar CCA and understanding its origin. Furthermore, it should be noted that CCA is an adenocarcinoma, a frequent histological subtype of metastatic liver cancer. Distinguishing between primary and metastatic lesions is crucial. Based on these different characteristics, it is essential to be aware of this point to avoid inaccurate data assessment. In my presentation, I will clarify the phenotypes of primary liver cancers (HCC, eHCC-CCA, and iCCA) and subsequently focus on iCCA phenotypes to highlight their distinctions. This analysis will be linked to treatment selection, including the identification of actionable mutations before genetic investigation.

Basic and Clinical Research of Cholangiocellular Carcinoma

BCR1-2

Current diagnosis of intrahepatic cholangiocarcinoma -From tumor localization to genetic abnormalities-

Dr. Tatsuya Kakegawa
Gastroenterology & Hepatology, Tokyo Medical and Dental University (TMDU) Japan

The incidence of intrahepatic cholangiocarcinoma(ICC) is increasing, with the highest rates seen in Eastern Asia when compared with Western countries. It is asymptomatic in the early stages, and about 20% of ICC are diagnosed incidentally, and no effective screening method has been established yet. It is important to know risk factors including primary sclerosing cholangitis and non-bile duct specific diseases as chronic hepatitis C virus and hepatitis B virus infection, non-alcoholic fatty liver disease, non-alcoholic steatohepatitis, alcoholic liver disease, and autoimmune hepatitis. Screening these populations by clinical examination, tumor markers, and abdominal ultrasound may aid in early diagnosis. On clinical examination, persistently elevated bilirubin levels, hepatobiliary enzymes, and the tumor markers CA19-9 and CEA are useful for auxiliary diagnosis. Contrast-enhanced CT(CECT) is widely used for differential diagnosis and localization evaluation of ICC from the viewpoints of simplicity, dissemination, and cost. Also Gd-EOB-DTPA contrast-enhanced MRI is useful for localization diagnosis because it shows the tumor as a clear low-signal area in the hepatocellular phase. The Kupffer phase of contrast-enhanced US(CEUS) depicts the tumor as a clear defect image, and its detection sensitivity is reported to be high. However, CEUS is only an adjunct to CECT and MRI due to the presence of blind spots and reproducibility problems. The most common extra-hepatic metastases of ICC are lung, bone, and distant lymph node metastases. The advantage of FDG-PET/CT is that it allows systemic search for these metastases in a single examination. Meta-analysis shows that "vascular invasion" is one of the prognostic factors, and it is important to accurately determine the presence or absence of vascular invasion. EUS is excellent for the diagnosis of hilar cholangiocarcinoma and is particularly useful in predicting the extent of bile duct invasion in cases of specific resection. Cholangiography has good spatial resolution and is useful in diagnosing the extent of cancer invasion. In ICCs near the porta hepatitis, mapping biopsy under direct view with cholangioscopy can diagnose the extent of bile duct invasion and reduce the number of positive cases of surgical resection margins. Liver tumor biopsy is also an option for atypical cases on imaging and for non-resected cases that require systemic therapy. Biopsy can help identify ICC-specific driver gene abnormalities, such as FGFR2 fusion gene and IDH1/2 mutations, and aid in the selection of therapeutic agents.
The new concept of neo-adjuvant therapy after resection has opened the new horizon in the liver cancer management. Recently, adjuvant therapy has been proposed to prevent tumor recurrence after surgery. This might be a promising concept for the future beyond the guidelines. It would still need further and larger study to conclude that this concept would be incorporated in the clinical practice guideline.

### Evaluation of data from the A-HOC (APASL Hepatology/Oncology Consortium) study of patients with hepatocellular cancer in Turkey

**Dr. Muhsin Murat Muhip Harputluoglu**

University Medical Faculty Liver Transplant Institute, Transplant Hepatology and Gastroenterology Dept Turkey

A-HOC (APASL Hepatology/Oncology Consortium) study is the abbre-viated name of study of 'Survey on Current Status and Treatment of Hepatitis and Liver Cancer in the Asia-Pacific Region'. This inter-national multicenter study examines the actual incidence and treatment of hepatocellular cancer in Asia Pacific countries, the background of viral and non-viral hepatitis, the actual situation of health and medical problems, and the development of new treatment methods in each country.

Aim of this presentation is to evaluate Turkey data in the A-HOC study. Basic patient data, physical examination findings at the time of carcinogenesis, tumor characteristics, treatment methods and dates and prognostic informations of the patients entered into the A-HOC REDCap system from centers in Turkey were analyzed.

### Comprehension of Asian HCC by A-HOC Study and APASL HCC Guideline

### Innovation on Clinical Management of Hepatocellular Carcinoma in the era of Systemic Therapy

**Dr. Cosmas Rinaldi Adithya Lesmana**

Department of Internal Medicine, Hepatobiliary Division, Dr. Cipto Mangunkusumo National General Hospital, Medical Faculty Universitas Indonesia, Indonesia

Hepatocellular carcinoma (HCC) is still becoming a major burden all over the world due to increase of metabolic liver disease despite hepatitis virus B and C infection. Metabolic dysfunction associated fatty liver disease (MAFLD) is an emerging disease, where it can lead to portal hypertension, liver cirrhosis, as well as liver cancer development. Most of the patients have come in the late stage of the disease. Therefore, early detection is still the main key for a success disease control and prolong patient's survival, however, in the case of MAFLD, it is not always easy to find early cancer development due to standard screening methods limitations. Innovation in endoscopic ultrasound (EUS) can be a promising secondary tool not only for confirming diagnosis, but also in the advance management.

Surgical approach is still the best treatment for managing liver cancer, however, the post-surgical recurrence rate is still high. In the interme-diate stage of HCC, the combination of loco-regional therapy with immunotherapy as well as oral systemic therapy have shown a satisfaction result when compared to loco-regional therapy alone.

### Advances in Hepatobiliary Imaging

**AH11-2**

#### Applications of artificial intelligence for hepatobiliary MR imaging

**Dr. Keitaro Sofue**

Department of Radiology Kobe University Graduate School of Medicine Japan

Global interest in artificial intelligence (AI) applications for MR imaging is growing rapidly, fueled by significant advances in computing power and new deep learning algorithms. Recently, deep learning reconstruction (DLR) algorithms have been developed for MR that are trained to improve image quality, and the combination of DLR with various sequences has produced favorable results in hepatobiliary MR imaging. DLR has been proven successful in reconstructing MR images with a high signal-to-noise ratio from undersampled k-space data to reduce acquisition times while maintaining high image quality. Additionally, a newly developed deep learning reconstruction method for upsampling resolution of low-resolution (superresolution) has been imple-mented into the MR machine. These DLR algorithms may help to improve visualization and characterization of hepatobiliary diseases. In this presentation, I would like to present our attempts to apply AI to improve image quality for hepatobiliary MR imaging.

### Big Data and AI for Hepatology

**BD1-1**

#### The usefulness of AI for tumor microenvironment analysis in HCC

**Dr. Hitoshi Mochizuki**

Genome Analysis Center / Department of Gastroenterology, Yamanashi Central Hospital Japan

Introduction: The tumor mass consists not only of a heterogeneous population of cancer cells but also a variety of resident and infiltrating host cells, secreted factors, and extracellular matrix proteins, collectively known as the TME(tumor microenvironment). The recent advances in machine learning are essential to elucidate what cells make up a TME and how these cells change and organize into different cellular communities in response to the signaling environ-ment.

Aims: In this study, we will evaluate TME based on DNA and RNA analysis and compare HCC with other cancer types, predict the efficacy of immune checkpoint inhibitors, and discuss issues in evaluating TME.

Methods: DNA and RNA were extracted from 441 surgical samples of Tumor (including 333 HCCs) during treatment. T cell prevalence can be estimated (General Additive Model) by se-queencing the rearranged T cell receptor-α gene (T Cell ExTRECT). Transcriptome analysis makes it possible to estimate the abundance of cells with well-known mRNA expression profiles, such as immune cells, from bulk RNAseq data (CIBERSORT: 22 cell types, xCell: 64 cell types).
Moreover, we analyzed using EcoTyper, a machine-learning framework for large-scale identification and validation of cell states and multicellular communities from bulk, single-cell, and spatially resolved gene expression data.

**Results:** The use of AI in TME Analysis of Tumors elucidates fundamental units of cellular organization in HCC and provides a framework for large-scale profiling of cellular ecosystems in any tissue. From a real-world clinical perspective, it was also shown that irAE caused by ICI (Immune Checkpoint Inhibitors) is caused in specific clusters.

**Big Data and AI for Hepatology**

**BD1-4**

**Application of Machine Learning in the Diagnosis and Management of Liver Disease**

**Dr. Masaya Sato**

Department of Clinical Laboratory Medicine, Graduate School of Medicine, The University of Tokyo Japan

While there has been significant progress in developing therapies for liver diseases, the prognosis for hepatocellular carcinoma (HCC), especially in advanced-stage patients, remains very poor. Artificial intelligence (AI), which combines computer science and mathematics, involves creating computer algorithms to improve the performance of computer programs. It does this by using various data sources and employing analytical or probabilistic models. The intersection of machine learning (ML) and the medical field has great potential to revolutionize diagnostic methods, particularly in laboratory medicine. Because liver diseases are complex and multifaceted, an ML approach that integrates multiple factors seems promising. This approach aims not only to improve diagnostic accuracy but also to predict how patients will respond to treatment and their future prognosis. Electronic medical records contain a wealth of data crucial for advancing medical research. By using AI and ML techniques and incorporating various factors into the analysis, we can enhance the precision of decision-making processes. This not only refines diagnostic accuracy but also helps predict outcomes in the intricate network of factors associated with liver diseases. In this presentation, we will explore the potential use of AI and laboratory medicine in the field of liver disease.

**Secondary Prevention of HBV-Related HCC**

**Dr. Young-Suk Lim**

Department of Gastroenterology Asan Medical Center, University of Ulsan College of Medicine Korea

Recently we analyzed the association between a broad range of serum HBV DNA levels and long-term HCC risk in a total of 6949 HBeAg-positive and HBeAg-negative, non-cirrhotic, treatment-naïve CHB patients who are not generally indicated for antiviral therapy by current practice guidelines because of no significant ALT level elevation. We found that the association between HBV DNA levels and HCC risk is not linear but parabolic in these patients. The HCC risk was highest at moderate HBV DNA levels around 6 log10 IU/mL, with decreasing HCC risk at higher and lower HBV DNA levels. Very high HBV DNA levels (>8 log10 IU/mL) showed the lowest HCC risk which was not significantly different from that of very low HBV DNA levels (≤4 log10 IU/mL).

Our additional studies have demonstrated that the level of serum HBV DNA at baseline impacts the on-treatment risk of HCC in non-cirrhotic patients with CHB. We found that patients with moderate baseline viral load, particularly around 6 log10 IU/mL, demonstrated the highest on-treatment HCC risk, despite long-term antiviral treatment. Compared with the matched untreated patients, the treated patients in the high and moderate viral load groups had a significantly lower risk of HCC. Nonetheless, the reduced risk of the treated patients in the moderate viral load group was significantly higher than that of the treated patients in the high viral load group. Initiating antiviral treatment at either high (≥8.00 log10 IU/mL) or low (3.30–4.99 log10 IU/mL) viral loads was associated with a significantly lower on-treatment risk of HCC compared to starting the treatment at a moderate baseline viral load (5.00–7.99 log10 IU/mL).

Therefore, early initiation of antiviral treatment with a high viral load (>8.00 log10 IU/mL) may maintain the lowest risk of HCC in those patients.

**Safety and Efficacy of Microwave ablation to HCC**
Yoshimi Yukawa-Muto1, Sawako Uchida1, Hiroko Ikenaga1, Naoshi Odaigiri1, Kohei Kotani1, Hiroyuki Motoyama1, Etsushi Kawamura1, Atsushi Hagiha1, Hideki Fujii1, Masaru Endo1, Norifumi Kawada1

Abstract Submission No. 101623

Background: We started using microwave ablation (MWA) in December 2019 and its use is increasing (43.3% of all ablation treatments in 2023). We reviewed the safety and efficacy of 47 nodules in 43 patients who underwent MWA in our department.

Methods: We assessed 1) frequency of sedation and complications, 2) complications from MWA treatment, and efficacy by 3) effectiveness determination after treatment, 4) local recurrence, and 5) comparison with RFA during the same period (n=76).

Results: Patients (n=43) had a median age of 75 (58-88) years, 60% male, background liver HBV/HCV/alcohol/other 7/23/7/6, first/recurrence 10/33. Nodules (n=47) had a mean diameter of 18.9±6.6 mm, left lobe/right lobe 8/39, internal/surface 26/21, with/without artificial ascites during MWA treatment 22/25. 1) Sedation was used in 21 patients (48.8%), with a mean dose of midazolam 1.9 mg. There were no complications due to sedation. 2) After MWA treatment, one patient developed an abscess in the treated area. 3) We had two residual cases with RFA during the same period (n=76). 4) The median nodule diameter was 18 (7-33) mm in the RFA group, which was significantly larger in the MWA group (p<0.001), but there was no difference from MWA treatment, and efficacy by 3) effectiveness determination after treatment, 4) local recurrence, and 5) comparison with RFA during the same period (n=76).

Conclusion: MWA is a safe and effective treatment method. Factors related to local recurrence could not be identified, so further follow-up are needed.

A prospective study of cardiohemodynamic profile changes in acutely decompensated cirrhosis and ACLF

Andrei Voiousu1,2, Victor Dragan1, Mihaela Birligea1, Anecta Vijan4, Caterina Delea4, Paul Balanscu2, Theodor Voiousu2, Andreia Bengus2, BogdanMateescu2, Ioana Daha2, Cristian Baicu6

1Dept. of hepatology, Osaka Metropolitan University Graduate School of Medicine Osaka Japan

Background: Microwave ablation (MWA) is a safe and effective treatment method. Factors related to local recurrence could not be identified, so further follow-up are needed.

Methods: This is a prospective, observational, follow-up study including patients admitted for acutely decompensated (AD) cirrhosis in a tertiary referral center. We performed ECG, echocardiographic assessment of cardiac function, and serum biomarker analysis (proBNP, TNF-a, Growth Arrested Specific-6, IL-6) at 3 time points: admission, 5-7 days later, and at one month. The main outcomes were mortality at one and 3-months. We explored serological and echocardiographic biomarkers of cardiac dysfunction to establish a cardiohemodynamic risk profile.

Results: A total of 1358 PSC cases reported from 299 hospitals were included. The prevalence of PSC from 2000 to 2023 was estimated to be 2.36 (95% CI: 1.82, 3.34) per 100,000. Males bore a relatively higher PSC prevalence than females (2.56 vs. 2.14 per 100,000). The prevalence of PSC more than doubled after 2010 than that before 2010 (1.68 vs. 0.67 per 100,000). Geographic distribution revealed the highest prevalence of PSC was in East China and the lowest in South China.

Conclusion: Comprehensive clinical-biological work-up of cardiohemodynamic status in acute decompensation of cirrhosis helps predict outcome. Median blood pressure is a simple indicator of increased risk for early death.

Funding: This work was supported by a grant of the Ministry of Research, Innovation and Digitization, CNCS – UEFISCDI project number PN-III-P.1-1.1-PD-2021-0180, within PNCDI III.

Background: Epidemiology of primary sclerosing cholangitis (PSC) is completely lacking in China. We aimed to investigate the prevalence by sex, time period, geographic distribution, and to depict the clinical features of PSC in China.

Methods: PSC cases reported during 2000 to 2023 in China were identified and included from two data sources: electronic medical records and systematical literature retrieval. The period prevalence of PSC in the general population was indirectly estimated using the multiplier method based on hospital-specific and nationwide clinic volumes.

Results: A total of 1358 PSC cases reported from 299 hospitals were included. The prevalence of PSC from 2000 to 2023 was estimated to be 2.36 (95% CI: 1.82, 3.34) per 100,000. Males bore a relatively higher PSC prevalence than females (2.56 vs. 2.14 per 100,000). The prevalence of PSC more than doubled after 2010 than that before 2010 (1.68 vs. 0.67 per 100,000). Geographic distribution revealed the highest prevalence of PSC was in East China and the lowest in South China.

**Preoperative Inflammatory Biomarker Analysis as a Predictor toward Hepatocellular Carcinoma Survival**

Muhammad Bilal Saifulhaq¹, Tohari Amin¹, Syifa Mustika², Shinta Oktya Wardhani³  
¹Internal Medicine Department, Saiful Anwar Regional Hospital and Brawijaya University, Malang Indonesia  
²Malang Indonesia  
³Brawijaya University, Malang Indonesia

**Background:** An elevated systemic inflammatory response (SIR) is associated with reduced survival in patients with operable cancer like hepatocellular carcinoma (HCC). This study aimed to determine whether SIR biomarker analysis obtained from routine preoperative blood tests can be used to predict overall survival in HCC patients who undergo surgery.

**Methods:** This comprehensive study was conducted according to the Preferred Reporting Items for Systematic-Reviews and Meta-Analysis (PRISMA) guidelines. We systematically searched ScienceDirect, Pubmed, Cochrane Library, ProQuest, and Google Scholar databases until the end of October 2023. We collected articles on real-world studies comparing systemic inflammatory response syndrome (SIRS) events after surgical treatment for predicting the overall-survival rate in patients with HCC. Pooled mean differences (MD) and 95% confidence Interval (CI) were used to determine overall events.

**Results:** Of 61 articles were included for this meta-analysis, there was a significant relationship between elevated C-reactive protein (CRP) (p<0.0001), C-reactive-protein-to-albumin ratio (CAR) (p<0.0001), Glasgow Prognostic Score/Modified Glasgow Prognostic Score (GPS/mGPS) (p<0.0001), Lymphocyte-to-CRP ratio (LCR) (p<0.005), Lymphocyte-to-monocyte ratio (LMR) (p<0.0001), Neutrophil-to-lymphocyte ratio (NLR) (p<0.0001) in a HCC patient who had bad overall-survival. We also conducted subgroup analysis by country associated with inflammatory markers and their correlation to mortality rate. Subgroup analysis was performed to eliminate any potential factors that might be caused by different heterogeneity levels.

**Conclusions:** These results consolidate the prognostic value of the CRP, CAR, GPS/mGPS, LCR, LMR, and NLR in patients with HCC. This is particularly true for the SIR biomarker analysis should form part of the routine preoperative and postoperative workup.

⁶Chandigarh India

**Background:** This study delved into cirrhosis-related infections to unveil their epidemiology, risk factors, and implications for antimicrobial decisions.

**Methods:** We analyzed acutely decompensated cirrhosis patients (n=971) from 2013-2023 at a tertiary center. Microbiological and clinical features based on infection sites (EASL criteria) and patient outcomes were assessed.

**Results:** Median age was 45 years; 87% were males with 47% having alcoholic hepatitis. Of these, 675 (69.5%) had infections; 305 (45%) were culture-confirmed. Notably, 71% of confirmed cases were MDRO-related, chiefly carbapenem-resistant (48%). MDRO prevalence was highest in pulmonary (80.5%) and skin-soft-tissue infections (76.5%). Site-specific distribution and antimicrobials were suggested. Predictive models identified hospitalization (OR:2.23), norfloxacin prophylaxis (OR:2.26), prior broad-spectrum antibiotic (BSAbx) exposure (OR:1.61), SIRS (OR:1.75), procalcitonin (OR:4.64), and End-stage (OR:1.41), with an AUC of 0.891 for infection prediction. For MDRO infection prediction, second infection (OR:7.19), norfloxacin prophylaxis (OR:2.76), prior BSAbx (OR:1.66), rifaximin (OR:0.44), CLIF-C-OF (OR:1.10), multi-site (OR:3.67), and polymicrobial infections (OR:4.55) yielded an AUC of 0.779 and 93% specificity. Norfloxacin prophylaxis, multisite infection, mechanical ventilation, prior BSAbx exposure, and infection as acute precipitant predicted carbapenem-resistant infection (AUC: 0.821).

**Deficient Hepatic Canalicular Exporter Proteins Associated with Chronic Drug-Induced Liver Injury**

Chhagan Bihari¹, Apoorv Giri¹, Archana Rastogi¹, Shiv Sarin¹

¹Institute of Liver and Biliary Sciences, Delhi Delhi India

**Introduction:** Inhibitory effects of various drugs on canalicular exporters can cause severe drug-induced liver injury (DILI). This study aimed to assess the canalicular exporters in liver biopsies of DILI and its association with chronic DILI.

**Patients and Methods:** Cases with the clinicopathological diagnosis of DILI with liver biopsies from January 2016- Dec 2020 were included in this study. Clinical and laboratory information were recorded. Immunohistochemically, BSEP, MDR3, and MRP2 were assessed. Chronic DILI was considered as biochemical nonresolution after six months of discontinuation of the drugs.

**Results:** 379 of 405 cases were analyzed (26 excluded due to incomplete data). Chronic DILI was noted in 41 patients (10.8%), and commonly implied drugs were complementary and alternative medicine (66%), antimycobacterial (6%), and antibiotics (5%). At least one transporter loss of expression (51 patients) was more in cases that had chronic DILI (27/41 (52.9%) vs 24/338 (7.1%), p<0.001). More than one deficient transporter in zone 2 and 3 (23 patients) was more pronounced in chronic DILI (19/41 (44%) vs. 4/338 (1.1%), p<0.001). Bile acids levels were higher in cases with deficient transporter expression (273, (IQR: 219-369) vs 98 (IQR: 72-183) micromol/L, P<0.001) and more prominently in those developed chronicity (354, (IQR: 305-439) vs 126 (IQR: 73-193) micromol/L, P<0.001). In the liver biopsies at baseline, mixed and cholestatic pattern (p=0.015), ductular, and canalicular cholestasis (p=0.001) were prominent, whereas fewer eosinophils (p=0.02) in those who developed chronic DILI.

**Conclusions:** Deficient expressed canalicular exporters and elevated bile acids were noted in DILI cases that progressed to chronic DILI.
Infections (culture-proven or probable), MDROs, carbapenem/pan- 
drug resistance, and second infections independently linked with mor-
tality (p<0.001), adjusted for age, leucocytosis, and organ failures. A 
model incorporating age (HR:1.02), infection (HR:1.52), prior hospi-
talization (HR:5.33), norfloxacin (HR:1.29), multisite infection 
(HR:1.47), and CLIF-C-OF (HR:1.17) predicted mortality with C-sta-
tistics of 0.782 (p<0.05).

Conclusion: High MDRO burden, especially carbapenem-resistant, 
necessitates urgent control measures in cirrhosis. Site-specific epide-
miology and risk models can guide empirical antimicrobial choices in 
cirrhosis management.

Background: This study delved into cirrhosis-related infections to un-
veil their epidemiology, risk factors, and implications for antimicrobial 
decisions.

Methods: We analyzed acutely decompensated cirrhosis patients 
(n=971) from 2013-2023 at a tertiary center. Microbiological and clin-
ical features based on infection sites (EASL criteria) and patient out-
comes were assessed.

Results: Median age was 45 years; 87% were males with 47% having 
alcoholic hepatitis. Of these, 675 (69.5%) had infections; 305 (45%) 
were culture-confirmed. Notably, 71% of confirmed cases were 
MDRO-related, chiefly carbapenem-resistant (48%). MDRO preva-
ience was highest in pulmonary (80.5%) and skin-skin-tissue infections 
(76.5%). Site-specific distribution and antimicrobials were suggested. 
Predictive models identified hospitalization (OR:2.23), norfloxacin 
prophylaxis (OR:2.26), prior broad-spectrum antibiotic (BSAbs) ex-
posure (OR:1.61), SIRS (OR:1.75), procalcitonin (OR:4.64), and HE-
grade (OR:4.1), with an AUC of 0.891 for infection prediction. For 
MDRO infection prediction, second infection (OR:7.19), norfloxacin 
prophylaxis (OR:2.76), prior BSAbx (OR:1.66), rifaximin (OR:0.44), 
CLIF-C-OF (OR:1.10), multi-site (OR:3.67), and polymicrobial infec-
tions (OR:4.55) yielded an AUC of 0.799 and 93% specificity. Nor-
flroxacin prophylaxis, multisite infection, mechanical ventilation, prior 
BSAbs exposure, and infection as acute precipitant predicted car-
banem-resistant infection (AUC:0.821).

Infections (culture-proven or probable), MDROs, carbapenem/pan-
drug resistance, and second infections independently linked with mor-
tality (p<0.001), adjusted for age, leucocytosis, and organ failures. A 
model incorporating age (HR:1.02), infection (HR:1.52), prior hospi-
talization (HR:5.33), norfloxacin (HR:1.29), multisite infection 
(HR:1.47), and CLIF-C-OF (HR:1.17) predicted mortality with C-sta-
tistics of 0.782 (p<0.05).

Conclusion: High MDRO burden, especially carbapenem-resistant, 
necessitates urgent control measures in cirrhosis. Site-specific epide-
miology and risk models can guide empirical antimicrobial choices in 
cirrhosis management.

Bacterial Vesicle Cargos induces Systemic Inflammation and 
hepatic Injury in Autoimmune Hepatitis

Swati Thangariyal1, Ashmit Mittal1, Anupama Kumari1, 
Chhagan Bihari1, Shiv Kumar Sarin1, Sukriti Baweja1

1Institute of Liver and Biliary Sciences Delhi India

Background: In autoimmune hepatitis (AIH), there is a growing em-
phasis on the pivotal role of the gut-liver axis, as attention turns toward 
microbial dysbiosis as a driving force in AIH pathogenesis. It is under-
stood that the bacterial microbiota promotes local and systemic inflam-
mation, which can promote inflammation in AIH. We propose that 
Bacterial vesicles(BV) as mediator of AIH, due to their potent immune 
stimulator composition and capability to influence inflammation.

Method: BVs isolated from AIH plasma [n=61, biopsy-proven, (HAI) 
score ≥2] and healthy control plasma (HC) n=30 was characterized by 
TEM, NTA, western blot and proteomics. Further, AIH and HC BV 
were adoptively infused intravenously in C57BL/6j female mice to de-
termine if BVs contribute to the acceleration and exacerbation of in-
flammation and hepatic injury.

Result: BVs were significantly higher in AIH patients than HC [10.5 
vs 3.7; p=0.003, 87.7 vs 10.3; p=0.015] the AIH BVs progressively 
increase with increasing HAI score[ r=0.62; p<0.001], transami-
nases{ALT, AST [r=0.59;p=0.001; r=0.57;p=0.001]} and IgG antibod-
ies[r=0.37;p=0.018]. The proteomics of AIH BV revealed >10-fold in-
crease in immunoglobins and complement-associated proteins includ-
ing complement C3, GAPDH, Transmembrane glycoprotein with 5 vir-
ulence factors having epitope mimicry helping in immune modulation 
and Adherence. miPreBase mapping identified an experimentally ver-
ified peptide sequence IYQIDNHQQARKPIAD of methyltransferase 
family mimicking component of pyruvate dehydrogenase complex of 
the host mitochondria. Upon, AIH-BV administration in mice within 
12h, the liver enzymes and liver weight index were elevated 
[AST(p=0.0286);ALT(p=0.0452); Li[ p=0.008)] than HC-BV. The 
liver histology showed raised focal acute inflammation in AIH-BV 
versus than HC-BV(p<0.001) with significantly high infiltration of 
F4/80 macrophages and Ly6G+ neutrophils in the liver (p<0.001).

Conclusion: The data suggests that BVs cargoes potentiates in pro-
moting systemic inflammation which could contribute to the develop-
ment and severity of AIH condition. These findings offer new insights 
into the role of BVs in microbiota-host interactions in AIH.
The impact of metabolic dysfunction on mortality in chronic hepatitis B with steatotic liver disease

Shang-Chin Huang1,2,3,4, Tung-Hung Su1,3, Tai-Chung Tseng1,5, Sih-Han Liao4, Shih-Jer Hsu4, Chun-Ming Hong4, Ting-Yuan Lan5, Chen-Hua Liu1,2,3, Hung-Chih Yang6, Chun-Jen Liu6, Pei-Jer Chen4, Jia-Hong Kao8

1Department of Internal Medicine, National Taiwan University Hospital, 2Division of Gastroenterology and Hepatology, National Taiwan University, 3Graduate Institute of Clinical Medicine, National Taiwan University College of Medicine, 4Department of Medical Research, National Taiwan University Hospital Taipei Taiwan, 5Department of Rheumatology, National Taiwan University Hospital.

Background: Steatotic liver disease (SLD), including metabolic dysfunction-associated steatotic liver disease (MASLD), is prevalent in the chronic hepatitis B (CHB) population. However, the impact of SLD subtypes on all-cause/cause-specific mortality among these patients remains unknown.

Methods: CHB patients with concurrent SLD were consecutively recruited at the National Taiwan University Hospital. MASLD, alcohol-associated liver disease (ALD), and crypto SLD were defined by the newly-proposed criteria. Cumulative incidences of all-cause and cause-specific mortality were compared after accounting for competing risks.

Results: From 2006 to 2021, 8,773 CHB patients with SLD were included. At baseline, CHB patients with concurrent MASLD (n=6,562) or ALD (n=55) were older, had a lower proportion of HBeAg positivity and lower levels of HBV DNA than crypto SLD patients (n=2,156). After a median follow-up of 9.1 years, ALD (adjusted HR [aHR]: 11.80, 95% CI: 5.89-23.60, p<0.001) and MASLD patients (aHR: 1.79, 95% CI: 1.24-2.58, p=0.002) had higher all-cause mortality risks than those with crypto SLD after adjustment for clinical and viral factors. Furthermore, cumulative metabolic dysfunctions, defined by the cardiometabolic criteria of MASLD, increased the risks of all-cause, liver-related, non-liver cancer, and cardiovascular mortality with a dose-dependent effect, contributing to the higher risks in MASLD than crypto SLD patients.

Conclusions: Among CHB patients with hepatic steatosis, concurrent ALD and MASLD increase the risk of all-cause mortality, and cumulative systemic metabolic dysfunctions dose-dependently increase all-cause and various cause-specific mortality. Refraining from alcohol intake and managing these metabolic risk factors are crucial for better survival in CHB patients.

Interferon reduce hepatocellular carcinoma risk in high-risk Asian patients with chronic hepatitis B

Qiran Zhang1, Feng Sun1, Yiqi Yu1, Ruirui You1, Yulei Sun1, Chao Qiu1, Jiming Zhang1, Wenhong Zhang1

1Huashan Hospital, Department of Infectious Diseases Shanghai China

Objective: To demonstrate the efficacy of pegylated interferon-α (PegIFNα)-based therapy and nucleoside analog (Nuc) in reducing hepatocellular carcinoma(HCC) risk in High-risk Asian patients with chronic hepatitis B.

Methods: The analysis was conducted in the data from a multi-center, prospective real-world study (OASIS Project) from China which started recruiting from October, 2020. Data on those who have completed 48 weeks of treatment and uploaded complete laboratory testing data were analyzed. Each patient was evaluated by algorithms that have been proven of good performance in Asian patients, including aMAP score, modified PAGE-B score and Toronto HCC Risk Index (THRI) if there was cirrhosis simultaneously, and the highest risk level was taken.

Results: A total of 8364 patients with PegIFNα-based therapy and 3422 with Nuc treatment were analyzed. At baseline, 52.60%, 39.90%...
and 7.50% of patients in IFN group were stratified into low-risk, intermediate-risk and high-risk for HCC, respectively. And in Nuc group, the ratio was 43.40%, 37.80% and 18.80%, respectively. After 48-week treatment, 21.3% of high-risk patients in IFN group changed into intermediate-risk, and 14.9% in Nuc group (Figure 1) changed. In Nuc group, the 1-year HCC incidence was higher in high-risk population (0%, 0.2%, 0.9% in low, intermediate and high risk, respectively, P=0.001). While in IFN group, the 1-year HCC incidence was similarly low in-risk and other population (0.1%, 0.1% and 0.3%, P=0.194).

Conclusions: Anti-viral treatments reduce the HCC risk in HCC patients, and IFN-based therapy seems superior.

Abstract Submission No. 100380

Optimizing a hepatitis C screening model for general population using easily accessible data

Chi Zhang1, Yiqi Liu1, Xinghua Fu1, Ao Jia1, Wanwan Shi1, Yanjie Lin1, Long Xu1, Hong Zhao1,2, Guiqiang Wang9

1Peking University First Hospital Beijing China, 2Peking University International Hospital Beijing China

Background: Globally, an estimated 58 million chronic hepatitis C virus(HCV) infections. Direct-acting antiviral medicines(DAAs) can cure more than 95% of persons with HCV infection, but access to diagnosis(20%) and treatment(15%) was low. We aimed to develop screening algorithms that accurately identifies HCV infection using easily accessible demographic parameters.

Methods: We obtained data from population-based cohorts National Health and Nutrition Examination Survey(NHANES 1990-2020), and divided them into training(6-cycles; n=46243) and testing(5-cycles; n=37060) cohort. Then, we applied logistic regression to calculate the odds ratio(OR) of 4 demographic factors(sex, ethnicity, blood transfusion history, birth year) for diagnosing HCV infection. Next, we developed and compared 9 machine learning(ML) algorithms to diagnose HCV infection in training cohort. Finally, we adopted the selected algorithm to establish the diagnostic model and test the performances.

Results: The overall cohort(n=83303) was 49.0% male; 37.9% White, 23.2% Black, 29.0% Hispanic, and 10.0% other; 8.8% of participants had a history of blood transfusion; with a mean birth year of 1972±23. The positive rates of anti-HCV and HCV RNA among studied population were 1.3% and 0.8%(unweighted). In multivariate analysis, all four parameters were significantly correlated with HCV infection: male sex(OR 2.01; P=0.001); Black versus White(OR 1.96; P=0.008); blood transfusion history(OR 2.14; P=0.001); born 1970 and before(OR 8.98; P=0.001). Comparing the AUC values of 9 ML algorithms in the training cohort, XGBoost was selected as the best prediction model. The AUC of the XGBoost model for diagnosing HCV infection was 0.891(95%CI 0.880-0.903) for the training set. In the testing set, the AUC was 0.843(0.827-0.858), and the sensitivity, specificity, PPV and NPV were 0.78, 0.78, 0.288 and 0.967, respectively.

Conclusions: To predict HCV infection in general population, only 4 easily obtained demographic features are needed using our ML model.

Abstract Submission No. 100555

WS-014

RISK FACTORS AND PROGNOSIS AFTER PRIMARY CURATIVE HEPATECTOMY IN HEPATOCELLULAR CARCINOMA PATIENTS

Hieu Banh1, Song Huy Nguyen Dinh1

1Cho Ray hospital Ho Chi Minh Vietnam

Background: We do this research at Cho Ray Hospital, Vietnam in order to evaluate some prognostic factors for recurrence, mortality, disease-free survival time (DFS) and overall survival time (OS) of HCC patients.

Method: retrospective cohort study

Result: From January 2015 to December 2019, there are 1704 patients whom received primary curative hepatectomy were enrolled in this study. All patients were followed up until June 2023. We recorded overall recurrent rate is 61.56% with 1-, 2- and 3-year recurrent rate are 56.69%, 74.24%, 84.04%, respectively. The overall survival rates at 3 and 5 years are 47.54% and 18.43%. Mean and median disease-free survival time are 16.8 and 9.5 months while mean and median overall survival time are 37.9 and 34.7 months. Univariate analysis showed that AFP level, vascular invasion, tumor number, tumor size, histological pattern, Edmonson-Steiner staging, tumor necrosis, accompanying resectable metastatic tumors, resection level are related to recurrence and DFS and OS, while underlying liver disease is only related to DFS. Logistic regression model showed that AFP level, vascular invasion, tumor number, tumor size, accompanying resectable metastatic tumors are independent prognostic factors for recurrence and mortality. Multivariate analysis using the Cox proportional-hazards regression model showed that AFP level, vascular invasion, tumor number, tumor size, accompanying resectable metastatic tumors are independent prognostic factors for recurrence and mortality.

Durvalumab + Tremelimumab (STRIDE) vs Durvalumab Alone for Unresectable HCC Patients: A MetaAnalysis

Ma. Regina D. Dimaculangan1, Faith Abigail Co1, Marianne Linley Sy-Janairo1

1Institute of Digestive and Liver Diseases, St. Luke's Medical Center - Global City Taguig Philippines

Background: Hepatocellular carcinoma (HCC) is the leading cause of mortality in cirrhotic patients, with an annual incidence of 1-6%. Most HCC patients usually require systemic therapy, being unresectable at the time of diagnosis. Durvalumab has gained popularity for patients with unresectable HCC versus sorafenib and atezolizumab + bevacizumab due to its safety profile, and the combination of Durvalumab (PD-L1 inhibitor) and Tremelimumab (CTLA-4 inhibitor) have shown additive antitumor activity and immunostimulatory effects. This study aims to compare the efficacy of STRIDE (Single Tremelimumab Regular Interval Durvalumab) compared to Durvalumab alone in unresectable HCC patients.

Methods: Major electronic databases and grey literature sources were searched up to June 2022 for randomized controlled trials assessing the effectiveness of STRIDE versus durvalumab monotherapy in unresectable HCC patients.

Results: The mortality rates between STRIDE and Durvalumab monotherapy were compared. Resulting I2 of 0% (p=0.72) implies that heterogeneity does not exist, hence a fixed effects model is preferred. Resulting pooled odds ratio 1.79 (95% CI 0.59 to 1.06) is not significant (Z=1.57, p=0.12), implying no significant difference between the two groups. The forest plot also shows that the hazard ratio intersects the 1 axis, suggesting that the odds ratio is not significant.

Conclusion: The addition of Tremelimumab in STRIDE (Single Tremelimumab Regular Interval Durvalumab) has no significant difference in the mortality rates among unresectable HCC patients versus Durvalumab alone. Hence, the additional costs and risks of STRIDE is upon the discretion of the patient and physician.
showed that tumor number was independent prognostic factors for DFS and OS.

Conclusion: tumor number is the independent prognostic factor for HCC recurrence and mortality.

Abstract Submission No. 101293
WS-015

Nonselective β blocker use does not impact on mortality in patients with hepatocellular carcinoma

Agnes Hin Yan Ho1,2, Philip Lung Wai Au Dong3, Terry Cheuk Fung Yip1,2,3, Mandy Sze Man Lai2,3, Vincent Wai Sun Wong2, Grace Lai Hung Wong1,2,3
1Department of Medicine and Therapeutics, The Chinese University of Hong Kong, Hong Kong Hong Kong China, 2Institute of Digestive Disease, The Chinese University of Hong Kong Hong Kong China, 3Medical Data Analytics Centre, The Chinese University of Hong Kong Hong Kong China

Background: Hepatocellular carcinoma (HCC) contributes to a substantial burden of mortality across the globe. Increasing evidence supports the role of non-selective beta-blockers (NSBB) in reducing liver decompensation and prolonging survival in cirrhotic patients. However, the effect of NSBB on liver-related mortality in HCC patients remains unestablished.

Materials and methods: All patients with HCC and esophageal and/or gastric varices from January 2000 to December 2020 were identified from a territory-wide database in Hong Kong. Participants were classified into three groups using a time-dependent covariate (i) propranolol users (ii) carvedilol users (iii) NSBB non-users. The primary endpoint was liver-related mortality in 5 years. Cause-specific hazard model was used for competing risk analysis. Liver transplantation and non-liver-related mortality were considered as competing events.

Results: A total of 5,454 patients with 4119 propranolol users, 86 carvedilol users, 1249 non-users (mean age 60.4±11 years, male 82.0%) were included in the analysis. Most patients had viral cirrhosis (78.3%). The use of propranolol and carvedilol did not have a significant impact on liver-related mortality (adjusted cause-specific hazard ratio [aC-SHR] 1.03, 95% CI 0.97-1.12, p=0.42; aC-SHR 0.90, 95% CI 0.57-1.43, p=0.67) and non-liver-related mortality (aC-SHR 0.99, 95% CI 0.86-1.15, p=0.94; aC-SHR 1.40, CI 0.75-2.65, p=0.293).

Conclusion: In this territory-wide retrospective study, use of NSBB did not impact on liver-related and non-liver-related mortality in HCC patients over a follow-up period of 5 years.

Abstract Submission No. 100663
WS-017

Sarcopenia is Associated with the Risk of Minimal Hepatic Encephalopathy in Patients with Cirrhosis

WASIT WONGTRAKUL1,2, Wimolrak Bandidniyanon1, Phunchai Charatcharoenwittaya1
1Division of Gastroenterology, Department of Medicine, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand Bangkok Thailand, 2Department of Research and Development, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand Bangkok Thailand

Background: Sarcopenia has gained significance in the evaluation of cirrhosis patients, and this nutritional status can have a detrimental impact on clinical outcomes, including minimal hepatic encephalopathy (MHE). This prospective study aimed to assess the association between sarcopenia and MHE in cirrhotic patients.

Methods: We enrolled outpatients with cirrhosis to evaluate the presence and severity of sarcopenia according to the 2019 criteria by the Asian Working Group for Sarcopenia. MHE was diagnosed using the paper-based Psychometric Hepatic Encephalopathy Score.

Results: Among the 210 patients (57.1% male, mean age 62.7±9.6 years) with cirrhosis, 54 (25.7%) exhibited sarcopenia, with 26 (12.3%) classified as having severe sarcopenia. Additionally, 37 (17.6%) were diagnosed with MHE. The prevalence of sarcopenia was significantly higher in cirrhotic patients with MHE compared to those without MHE (45.9% vs. 21.4%, p=0.002). MHE was notably associated with education level, Mini-Mental State Examination score, and a history of hepatic decompensation. Conversely, no significant associations were observed regarding gender, BMI, comorbidities, sleep quality, etiology and severity of liver disease assessed by MELD score and transient elastography. In a multivariable logistic model, MHE was significantly associated with age (adjusted odds ratio [aOR] 1.08, 95% CI 1.02-1.13), sarcopenia (aOR 3.29, 95% CI 1.44-7.50), and a history of overt hepatic encephalopathy (aOR 7.40, 95% CI 1.20-45.56) and variceal bleeding (aOR 3.13, 95% CI 1.38-7.10). Furthermore, severe sarcopenia was independently associated with MHE (aOR 3.64, 95% CI 1.32-10.05).

Conclusions: Sarcopenia is not uncommon among outpatients and is an independent risk factor for MHE in cirrhotic patients.

Early Clinical Features of Peritoneovenous Shunt in Patients with Decompensated Liver Cirrhosis
Asako Nogami1, Shingo Koyama1, Shihyao Cheng1, Yuya Koike2, Michihiro Iwaki1, Takashi Kobayashi1, Satoru Saito3, Daisuke Utsunomiya1, Atsushi Nakajima1, Masato Yoneda1
1Yokohama City University Graduate School of Medicine Yokohama Japan, 2Saiseikai Yokohama Nanbu Hospital Yokohama Japan, 3Sanno Hospital Tokyo Japan

Background and Aims: Refractory ascites affects the prognosis of liver cirrhosis. Peritoneovenous shunt (PVS) placement is a palliative treatment for refractory ascites that is expected to improve the patient’s quality of life; however, it is associated with serious complications, such as heart failure. Thus, understanding the clinical course and risks of complications after PVS placement is important. We aimed to evaluate the early clinical features after PVS placement for refractory ascites associated with liver cirrhosis.

Methods: This was a retrospective study of 14 patients with refractory ascites with decompensated cirrhosis who underwent PVS placement between June 2011 and June 2023. The clinical characteristics, changes in cardiothoracic ratio (CTR), and laboratory data were evaluated.

Results: No serious complication associated with the procedure occurred in all cases. Ten and four patients had Child-Pugh classes B and C, respectively. Increased brain natriuretic peptide (BNP) and D-dimer levels, decreased platelet count, and slightly worsening of CTR were observed two days after PVS placement; however, all cases tended to improve after seven days. The mean PVS patency was 345.4 days, and the median survival after PVS placement was 474.4 days. Although patients with class B cirrhosis tended to have longer PVS patency, there was no significant difference in patency between patients with class B and C cirrhosis.

Conclusions: PVS placement for refractory ascites is a technically feasible palliative therapy. Evaluating changes in CTR, platelet count, and BNP and D-dimer levels may be useful for early prediction of the efficacy of PVS placement.

Morphofunctional restoration of the hepatopulmonary axis in the early stages of liver cirrhosis
Liilit Arshakyan1
1researcher Yerevan Armenia

One of the peculiarities of the liver is that it is connected to the portal system and the lungs in a sequential manner. Pulmonary complications during cirrhosis play an important part in the manifestations of the disease and the quality of life of patients with this disease can contain a significant signal in the chain of the hepat-Pulmonary early differential diagnosis of complications of the disease will make it possible to prevent serious consequences and irreversible damages. It was the basis to set a goal to study the spectrum of hepatopulmonary complications in the early stages of liver cirrhosis development with personalized analysis.

In this study the patterns of serum protein electrophoresis results were evaluated against histopathological abnormalities in the liver and lungs, with the application of Hematoxylin and eosin (H&E) and

When pre-symptoms of liver cirrhosis are clearly observed in the anatomical and histological features during the initial stage of cirrhosis, lung lesions are quite severe, according to the developed histopathological scale. There is a decrease in the tendency to pulmonary lesions over the two-week post-poisoning after period, and in males. Thus, in the acute and/or subacute stages of cirrhosis development, hormonal features play a crucial role in determining the hepatopulmonary axis differential diagnosis along with behavioral and emotional characteristics. We are sure that at some point in time there comes a moment of harmony (like in life, between males and females) when pathological processes manifest in the same way in both sexes.

Performance of aMAP, FIB-4, and APRI for Predicting F2 Fibrosis in Chronic Hepatitis B Patients
Apichat Kaewdech1, Suraphon Assawasuwannakit2, Pimsiri Sripongpun2, Naichaya Chamroonkul2, Teerha Piratvisuth3
1Gastroenterology and Hepatology Unit, Division of Internal Medicine, Faculty of Medicine, Prince of Songkla University Hatyai Thailand, 2Department of Medicine, Panyananthaphikkhu Chonprathan Medical Center, Srinakharinwirot University Nonthaburi Thailand, 3NKC Institute of Gastroenterology and Hepatology, Songklanagarind Hospital, Prince of Songkla University Hatyai Thailand

Background: In line with WHO’s 2030 hepatitis elimination target, effective chronic hepatitis B (CHB) strategies are vital. For those with HBV DNA >2000 IU/mL and persistently normal ALT, fibrosis assessment via transient elastography (TE) is advised. The aMAP score, recently introduced for fibrosis staging in CHB patients, has yet to be validated for assessing significant fibrosis.

Method: In this cross-sectional study, CHB patients with concurrent laboratory data and TE results within three months were evaluated. A TE value of at least 7 kPa indicated significant fibrosis. The aMAP score’s efficacy was compared to the Fibrosis-4 index (FIB-4) and the aspartate aminotransferase to platelet index (APRI) in predicting F2 fibrosis. Metrics such as sensitivity, specificity, NPV, and PPV were assessed.

Results: Among the 628 analyzed CHB patients (mean age 48.6 years; 51% male; 79.8% HBeAg-negative; median HBV DNA 2042.5 IU/mL), the areas under the receiver operating curves for F2 fibrosis prediction were 0.693, 0.7061, and 0.7254 for aMAP, FIB-4, and APRI scores respectively. Statistical comparisons with aMAP showed no significant difference (p-values: 0.398 for FIB-4 and 0.137 for APRI). Optimal aMAP score thresholds were determined at 93% sensitivity (cutoff: 40) and 89% specificity (cutoff: 55).

Conclusions: The aMAP score emerges as a potential non-invasive metric for predicting significant fibrosis in CHB patients, with a 40 cutoff optimal for ruling out significant fibrosis. However, its performance mirrors existing scores. A more accessible, simplified score for assessing fibrosis is desired, especially when TE is unavailable in resource-limited settings.

GENETIC FEATURES OF PATIENTS WITH WILSON’S DISEASE IN REPUBLIC OF MOLDOVA: A PILOT STUDY

Veronica Cumpata1,2, Adela Turcanu1,3, Lucia Mazur-Nicorici1
1Nicolae Testemitanu State University of Medicine and Pharmacy of the Republic of Moldova Chisinau Moldova, 2The Clinic of Gastroenterology and Hepatology/ HELPA Chisinau Moldova

INTRODUCTION: Wilson disease (WD), a rare metabolic disease, is an autosomal recessive disorder associated with phenomonal mutational polymorphism and high clinical variety.

OBJECTIVE: To assess epidemiological characteristics and genetic features of Moldovan patients with WD.

METHODS: It was conducted a retrospective study on 108 patients suspected of WD, between 2006 and 2023. The Leipzig Scoring System was used to specify the diagnosis.

RESULTS: Of 108 persons, 57.4% (62/108) were male. The mean age was 16 years (range 3-63 years). All persons were of Caucasian origin, and 79% were of Moldovan ethnicity. No consanguineous relationships have been described. Patients mostly come from the city (59.4%) and south (15.94%) of the country. Hepatic onset was more frequent in women (45.8%, p<0.01) and neurological in men (61.5%, p<0.05). In 61.35% of the performed genetic tests, mutations were detected, of which 70.2% are pathogenic variants. The most frequent mutation identified is p.H1069Q (62.1%), of which 36.1% are in homozygous recessive state and 41.7% - associations with other variants (pathogenic, benign, or uncertain), and the second mutation is unknown in 22.2%. In 52.8% of cases, this mutation is associated with liver damage, which was diagnosed at the onset or during the natural evolution of WD.

CONCLUSIONS: p.H1069Q represents the most frequent pathogenic variant identified in the Republic of Moldova. Patients with hepatic presentation are diagnosed at younger ages, while those with neuro-psychiatric type are diagnosed at older ages and with longer diagnosis delays.

Investigating unique clinical, pathological traits, and genetic variations in MAFLD among Indians.

Ankita Chatterjee1, Bandana Mondal1, Kausik Das2, Dipankar Mondal1, Ranajay Ghosh1, Abhijit Chowdhury3, Priyadarshini Basu4
1JOHN C MARTIN CENTRE FOR LIVER RESEARCH AND INNOVATIONS KOLKATA India, 2Institute of Post Graduate Medical Education and Research Kolkata India, 3National Institute of Biomedical Genomics Kalyani India

Background and aims: Fatty liver disease (FLD) is characterized by excessive fat accumulation in the liver and is closely linked to metabolic syndrome (MetS). However, the unique features and genetic factors influencing FLD in the presence or absence of MetS remain poorly understood. We aimed to investigate the clinical and genetic aspects of fatty liver disease (FLD) in individuals with and without metabolic syndrome (MetS).

Methods: A cohort of 551 individuals, with and without fatty liver, was categorized into four groups based on metabolic dysregulation: MAFLD, NAFLD, MetS, and healthy controls. Our study analysed clinico-patological attributes and associations of SNPs with MAFLD.

Results: The results showed that nearly half of the participants had FLD (47.2%), and the majority had MetS (71.87%). MAFLD individuals exhibited significantly higher age, increased adiposity, more severe diabetes, abnormal lipid profiles, elevated liver damage markers, CRP levels, decreased bone mineral content, and more extensive liver damage. Notably, both obese and non-obese individuals in this group displayed these adverse characteristics. Furthermore, the study identified 21 genetic variants associated with the increased risk of MAFLD, mapped in SAMM50, PNPLA3, TM6SF2, CECR5, TTC39B, SLC9A9, and PDXDC1. Additionally, rs7200543-AA carriers among MAFLD patients showed poorer skeletal health.

Conclusion: Our study demonstrated that FLD in combination with MetS results in the most severe disease phenotype. It highlighted the importance of considering both clinical and genetic factors when studying FLD and provided insights into the complex interplay between genetics and metabolic disorders in liver disease.

Abstract Submission No. 100323

Hepatic lobular inflammation is the most impacted prognostic factor in MAFLD: A Multi-Center study

Tsubasa Tsutsumi1, Hldeki Fujii1, Takumi Kawaguchi1, Miwa Kawanaka2, Hirikazu Takahashi3, Yoshihiro Kamada4, Sumida Yoshiro5, Hldeki Hayashi5, Michihito Iwaki5, Satoshi Odeda6, Shinichi Aishima7, Masato Yoneda8, Hidenori Toyoda9, Atsushi Nakajima10
1Kurume University School of Medicine Kurume Japan, 2Osaka Metropolitan University Osaka Japan, 3Kawasaki Medical Schoo Okayama Japan, 4Saga University Hospita Saga Japan, 5Osaka University Graduate School of Medicine Suita Japan, 6International University of Health and Welfare Tokyo Japan, 7Gifu Municipal Hospital Gifu Japan, 8Yokohama City University Graduate School of Medicine Yokohama Japan, 9Ogaki Municipal Hospital Ogaki Japan, 10Kyusyu University Fukuoka Japan

Background and Aims: Metabolic dysfunction-associated fatty liver disease (MAFLD) captures patients with fatty liver at high risk. However, limited information is available on the prognosis of MAFLD and prognostic liver histology. We aimed to investigate the prognosis of patients with biopsy-proven MAFLD and the most important histological finding associated with the prognosis using a multi-center longitudinal cohort.

Methods: We enrolled 1,444 patients with fatty liver who underwent liver biopsy (age 57, BMI 27.4). Patients were classified into the following groups: the MAFLD group, non-MAFLD group (steatosis without metabolic dysfunctions), or Burnt-out group (no steatosis on biopsy). Kaplan-Meier analysis and decision-tree analysis were performed to investigate the difference in mortality in these subgroups and the most impacted histological finding related to the prognosis of each group, respectively.

Results: During the 9,083 person-years of observation, 4.3 person-years of deaths occurred, and 84.2% (32/38) of these were patients in the MAFLD group. Significant differences were seen in prognosis among the three groups (log-rank p=0.0009). Ten-year survival rate was 65.6% in the MAFLD group, while no patient died in the non-MAFLD group. The MAFLD group showed the highest proportion of high NAFLD activity scores. Although hepatic fibrosis was the histological finding most impacted on mortality in the Burnt-out group, hepatic inflammation was identified as the most impacted prognostic finding in the MAFLD group.

Conclusions: We demonstrated that patients with MAFLD have a worse prognosis than patients with non-MAFLD. Hepatic inflammation rather than fibrosis was the most impacted prognostic histology in patients with MAFLD.
Long-term Risks for Cirrhosis and Hepatocellular Carcinoma Across Steatotic Liver Disease Subtypes

Aim: The prospective study aimed to investigate the long-term associated risks of cirrhosis and hepatocellular carcinoma (HCC) across various subtypes of steatotic liver disease (SLD).

Method: We enrolled 332,175 adults who participated in a health screening program between 1997 and 2013. Participants were categorized into various subtypes, including metabolic dysfunction-associated steatotic liver disease (MASLD), MASLD with excessive alcohol consumption (MetALD), and alcohol-related liver disease (ALD), based on ultrasonography findings, alcohol consumption patterns, and cardiometabolic risk factors. We utilized computerized data linkage with nationwide registries from 1997 to 2019 to ascertain the incidence of cirrhosis and HCC.

Result: After a median follow-up of 16 years, 4,458 cases of cirrhosis and 1,392 cases of HCC occurred in the entire cohort, resulting in an incidence rate of 86.1 and 26.8 per 100,000 person-years, respectively. The ALD exhibited the highest incidence rate for cirrhosis and HCC. ALD, and ALD, respectively, when compared to non-SLD without cardiovascular disease in South Indian population

Dhivya Elango¹, Kandasamy@Kumar E¹, Poppy Rejoice¹, Shaifique A¹, Geetha D¹

¹Tirunelveli medical college tirunelveli India

BACKGROUND: Metabolic associated fatty liver disease (MAFLD) is the latest entrant in hepatology. There is paucity of data regarding MAFLD in the general population so this study aims to identify the prevalence and risk factors for MAFLD among the ethnic South Indian population.

METHODS: Demographic details, lifestyle habits, anthropometric details, biochemical tests and ultrasound findings of the subjects were recorded. A diagnosis of MAFLD was made with evidence of fatty liver along with one criteria for metabolic dysfunction. Statistical analysis was done using SPSS version 23, Chi Square test and Independent t test.

RESULTS: 2290 subjects were included in this study with mean age as 43.83 with SD of 13.601, age range from 19 to 78 and majority were in 41 to 50 age group (27.95%). Males were more common (58.95%). 27.95% of study population have MAFLD(640 subjects). Alcohol consumption was more commonly seen compared to other risk factors (33.62%) and hypertension was less commonly seen (23.58%) for developing MAFLD. Risk is more in smokers, alcohol consumption, diabetics, hypertensives, those with age more than 40 and females. On applying Chi square test significant association for getting MAFLD was found in diabetics, hypertensives and those with age more than 40. On applying Independent t test there was significant difference between MAFLD and Non MAFLD with p value<0.05 in all parameters except uric acid.
CONCLUSION: Our study highlights the increasing burden of MAFLD in the community and to address the growing issue with targeted therapy for comprehensive patient care.

WS-027

GENDER RELATED ASSOCIATION OF BMI AND AGE WITH MAFLD / SLD IN PAKISTANI POPULATION: CROSS SECTIONAL

Mohammad Khoso1, Nazish Butt2
1JPMC Karachi Karachi Pakistan, 2JPMC Karachi Karachi Pakistan

Background: When there is excessive fat in liver, condition is called (MAFLD). MAFLD most commonly occurs in patients having certain underlying conditions such as hyperlipidemia, metabolic syndrome, central obesity, hypothyroidism, polycystic ovarian syndrome, and type 2 diabetes mellitus. This study is designed to determine the link of MAFLD with age, gender, and body mass index.

METHODS: It is the cross-sectional, retrospective, single center study that was conducted in the Department of Gastroenterology & Hepatology, Jinnah Postgraduate Medical Center (JPMC), Karachi for a period of January 2020 to September 2023. All the adult males and females admitted and/or presented in the out-patient-department (OPD) with clinical signs & symptoms suggesting fatty liver disease were included for this study. Baseline and clinical data were collected by association of age, gender, and BMI with MAFLD was analysed using SPSS version 26.0.

RESULTS: Total 1140 participants were included for initial analysis, the overall prevalence of MAFLD was 72.5% (n = 827). Patients with MAFLD were older (42.1±10.2) years as compared to controlled group (42.5±11.2) years and female patients were more prevalent than males, 78.6% vs. 21.4%, but they are insignificantly associated with MAFLD. Overweight patients were more likely to have MAFLD as compare to MAFLD with controlled and Obese.

CONCLUSION: A multitude of factors showed significant association with MAFLD and need to be researched in-depth to better understand the mechanisms behind them and the therapeutic measures that can be taken. Surprisingly, age and gender did not show significant association with MAFLD but BMI did.

Abstract Submission No. 101764
WS-028

RCT evaluating efficacy of Saroglitazar vs OCA in patients of MAFLD/NASH

CTR/2023/03/050213

Kalpana Acharya1, Prof GM Gulzar2, Prof and Head Altaf Shah3
1Department of Gastroenterology Srinagar India, 2Prof, Shere I kashmir institute of Medical Sciences Srinagar India, 3Prof and Head Shere I kashmir institute of Medical Sciences srinagar India

Aim: NAFLD/NASH is a burgeoning cause for cirrhosis worldwide, but pharmacotherapy for the same remains elusive. Only Saroglitazar so far has received acceptance from DCGI. This study explores the potential efficacy of Obeticholic acid in patients of MAFLD/NASH.

Methods: This prospective, comparative study evaluated efficacy of Obeticholic acid 10 mg (n =50) and Saroglitazar 4mg (n =50) in patients of NAFLD/NASH. All patients were analyzed for change in primary outcomes i.e., Fibrosis (LSM) and steatosis (CAP) at baseline and at 24 weeks measured through fibroscan and secondary outcomes including, ALT, AST, Lipid profile and non invasive scores of fibrosis.

Results: In Obeticholic acid group LSM reduced by 20.9%, p value <0.001 while in Saroglitazar limb it reduced by 23.20% p value <0.001 at 24 weeks, however there was no difference between 2 groups p value < 0.26. CAP in Obeticholic acid group reduced by 21% p value <0.001 while in Saroglitazar limb it reduced by 10.70 % P value, 0.001. CAP value reduced more significantly in Obeticholic acid group p value 0.01. Secondary endpoints , also improved significantly in both the groups post 24 weeks of treatment.

Conclusion: Obeticholic acid has a comparable effect with Saroglitazar in reducing Fibrosis (LSM), ALT, AST and serum Triglyceride, while it has an edge over the Saroglitazar in reducing Steatosis (CAP).

Clinical features of MetALD and ALD in patients with hepatocellular carcinoma

Yuri Ogasawara1, Tomomi Kogiso1, Kentaro Horuchi1, Makiko Tanai1, Katsutoshi Tokushige1
1Tokyo Women's Medical University Tokyo Japan

Aim: A subgroup of individuals with intermediate alcohol consumption among steatotic liver diseases has been classified as metabolic dysfunction-associated steatotic liver disease (MetALD). Therefore, we compared the clinical features of MetALD and alcohol-associated liver disease (ALD) in patients with hepatocellular carcinoma (HCC).

Method: The study included: 1) Cross-sectional comparison of 64 cases of MetALD-HCC and 207 cases of ALD-HCC diagnosed at our institution from 1989 to 2021, and 2) Retrospective cohort analysis of 271 cases post HCC diagnosis, including mortality rate, causes of death, and analysis of mortality risk factors.

Results: The median age of was 66/52 years, with a male ratio of 92.2/93.7%. The average daily ethanol intake was 32/108g. HCC stage IV was 9.4/6.3%. Significant differences (p<0.05) between the two groups were observed in age, prevalence of hypertension (67.2/51.7%), dyslipidemia (37.5/16.9%) and cirrhosis (65.6/77.8%), albumin (Alb) 4.4/3.7 mg/dL, total bilirubin (T-Bil) levels 0.5/0.9 mg/dL, and platelet count 25/10 × 10^9/L. 2) The 5-year survival rates were 69.6/49.5%, significantly lower in the ALD-HCC group (p<0.01). Mortality due to infections (20.8/5.8%) was significantly higher in the MetALD-HCC group (p<0.02). Risk factors for death included Child-Pugh classification at diagnosis, HCC stage, and curative treatment feasibility. Additionally, non-complication of dyslipidemia in the MetALD-HCC group and old age and low Alb levels in the ALD-HCC group were extracted.

Conclusion: The MetALD-HCC group showed a better prognosis compared to the ALD-HCC group. However, attention is needed for non-elder-related deaths in the MetALD-HCC group.

Daily nucleotide analogues reduces the severity of COVID-19 in patients with chronic liver disease

Qian Zhu1, Ke Qiu1, Dachuan Cai1, Peng Hu1, Hong Ren1
1Department of Infectious Diseases, Key Laboratory of Molecular Biology for Infectious Diseases (Ministry of Education), Institute for
Viral Hepatitis, the Second Affiliated Hospital, Chongqing Medical University Chongqing China

**Background:** The effect of nucleotide analogues (NAs) against severe acute respiratory coronavirus 2 (SARS-CoV-2) infection and associated clinical outcomes among patients with chronic liver disease (CLD) remain unclear.

**Methods:** 579 CLD patients with available data of SARS-CoV-2 infection were included in this study during Omicron subvariants BA.5 wave. Demographic and clinical data were collected by standardized questionnaires and electronic medical records. Multivariable logistic regression models were used to assess the association between NAs and coronavirus disease 2019 (COVID-19) outcomes.

**Results:** CLD patients with daily NAs therapy had significant lower proportions of SARS-CoV-2 infection (72.8% vs. 84.3%, p=0.001), severe COVID-19 (2.3% vs. 7.8%, p=0.003) and COVID-19-related death (1.7% vs. 5.3%, p=0.016) than those without NAs therapy. Similar trends were also shown in other severe outcomes including intensive care unit (ICU) admission, mechanical ventilation and overall death although there was no significant difference. Multivariable logistic regression analysis further demonstrated the negative associations between daily NAs therapy and SARS-CoV-2 infection (adjusted odd ratio [aOR], 0.61; 95% confidence interval [CI], 0.36-1.02; p=0.059), severe COVID-19 (aOR, 0.26; 95% CI, 0.09-0.77, p=0.015) and COVID-19 related death (aOR, 0.23; 95% CI, 0.06-0.91, p=0.036).

**Conclusions:** Daily NAs therapy reduces the severity of COVID-19 among CLD patients and has potential protective effect against Omicron infection. This finding suggests that NAs might be used as pre-exposure prophylaxis or early treatment of COVID-19, especially for immunocompromised patients including decompensated cirrhosis with suboptimal vaccine responses and those CLD patients for which hepatic safety concerns arise with other antiviral drugs.

**Pattern of Liver Injury and its Outcome in Covid-19 Patients**

Zahabia Sohail1, Masood Karim1, Om Parkash1

1The Aga Khan University Karachi Pakistan

**Objective:** COVID-19 is a highly contagious respiratory disease caused by the SARS-CoV-2 virus. Evidence suggests that it can cause liver damage through various mechanisms, but the prevalence and clinical significance of abnormal liver function tests (LFTs) in patients with COVID-19 is relatively unexplored.

**Method and Material:** Descriptive cross-sectional study was conducted at the Aga Khan University Hospital, Karachi from 26th 61 February 2020 till June 2020. All patients above 18 years of age, admitted with confirmed COVID-19 infection were included. Data on patient demographics, clinical symptoms, laboratory test results, length of hospital stay, and clinical outcomes was collected. Statistical analysis of the variables was conducted using SPSS.

**Results:** A total of 533 hospitalized patients were included in this study, with a mean age of 53±16 67 years, of which 61.5% were male. The most prevalent comorbidities were hypertension 62 (42%) and diabete mellitus (36%). LFTs were found to be deranged in 92% of the total 69 patients, with Aspartate aminotransferase (81%), Gamma-glutamyl transferase (69.4%), and Alanine transaminase (66.8%) being the most commonly affected liver enzymes. On comparative analysis, deranged LFTs showed significant correlations with the male gender (p-value 0.012), age group >60 years (p-value 0.001), fever (p-value <0.001), cough (p-value 73 0.028), shortness of breath (p-value 0.021), hemoglobin levels (p-value 0.003), serum 74 sodium (p-value 0.006), serum C-Reactive Protein (p-value <0.001) serum ferritin (p-value <0.001), serum Lactate Dehydrogenase (p-value <0.001), and length of hospital stay (p-value <0.001).

**Conclusion:** The study showed a high prevalence of abnormal liver enzymes in mild-moderate COVID-19 cases. Our findings suggest a correlation between abnormal liver function tests and various demographic and clinical factors, but further investigation is needed to determine the clinical significance of liver injury in COVID-19 patients. These findings have important implications for patient management and outcomes.

**RCT: Reduction of Bilirubin after Steroids for Biliary Atresia**

Novi rahayu Arianti1, 2, Bagus Setyoobedi1, 2, Rendy aji Prihatiningtyas1, 2

1Soetomo hospital Surabaya Indonesia, 2Airlangga University School of Medicine Surabaya Indonesia

**Background:** Biliary atresia remains a global public health problem. Although Kasai therapy has been established for a long time, the need for liver transplantation is still high. Liver transplantation is not available in all countries. Pathogenesis of autoimmunity in development of biliary atresia obliterator fibrosis is currently widely discussed. This study analyzes the effect of methylprednisolone on bilirubin levels in biliary atresia infants.

**Methods:** This study is a RCT on infants aged 2 week - 3 months with biliary atresia at Dr Soetomo General Academic Hospital, Surabaya. Subjects were grouped into methylprednisolone vs placebo group. Methylprednisolone was given at a dose of 2 mg/kg/day for 14 days and bilirubin levels were assessed before and after treatment. Data analysis was performed with SPSS.

**Results:** The study included 40 infants, 20 in the methylprednisolone group and 20 in the placebo group. Pre-treatment bilirubin levels were not significantly different between the methylprednisolone and placebo groups (direct bilirubin 9.87 (6.11-14.20) mg/dL vs 6.68±2.44 mg/dL; total bilirubin 9.87 (6.11-14.20) mg/dL vs 9.44±3.91 mg/dL; p>0.05). Bilirubin reduction was significantly greater with methylprednisolone than with placebo (direct bilirubin 3.88±2.58 mg/dl vs 1.40±2.22 mg/dl; p=0.002; total bilirubin 4.45 (3.17-7.65) mg/dL vs 2.39±2.30 mg/dL; p=0.03).

**Conclusions:** Methylprednisolone reduced bilirubin levels at 2 weeks of therapy. Bilirubin improvement with steroids supports the evidence of immunity in the pathogenesis of biliary atresia.

Key word: Biliary atresia, Bilirubin level, Methylprednisolone

**Modified ALBI grade and platelet count to predict high-risk varices in hepatocellular carcinoma**

Prooksa Ananchuensook1, 2, 3, 4, 5, Kingkomon Piyawannassuth4, Siriporn Sukawatamnuay1, 2, 3, 4, Panarit Thaimassage1, 2, 3, 4, Nipaporn Siripoon6, Supachaya Sripoosananphan1, 2, 3, 4, Kessarin Thanapirom7, Piyawat Komolmit1, 2, 3, 4

1Chulalongkorn University Bangkok Thailand, 2Center of Excellence in Liver Diseases, King Chulalongkorn Memorial Hospital, Thai Red Cross Society Bangkok Thailand, 3Center of Excellence in Hepatic
Fibrosis and Cirrhosis, Faculty of Medicine, Chulalongkorn University Bangkok Thailand, Department of Medicine, Faculty of Medicine, Chulalongkorn University Bangkok Thailand, a) Division of Gastroenterology, Department of Medicine, Faculty of Medicine, Chulalongkorn University Bangkok Thailand, b) Academic Affair, Faculty of Medicine, Chulalongkorn University Bangkok Thailand, c) Chulalongkorn University, International Medical Program (CU-MED), Faculty of Medicine, Chulalongkorn University Bangkok Thailand

Background: Baveno VII employs non-invasive tests to rule out high-risk varices (HRV) in cirrhosis; however, this approach doesn’t extend to HCC. We aim to validate and refine the previously studied Albumin-bilirubin and platelet (ALBI-PLT) score for predicting HRV in HCC.

Methods: Our retrospective study included HCC patients with EGD reports and no prior upper GI bleeding at King Chulalongkorn Memorial Hospital from 2019 to 2023. F2 or F3 esophageal varices (EV) were defined as HRV. ALBI-PLT was computed following Chen et al. Modified ALBI-PLT (mALBI-PLT) calculated by combining mALBI grading (1 point for grade 1 or 2a; 2 points for grade 2b or 3) and platelet (1 point for > 150,000 /µL; 2 points for ≤150,000 /µL).

Results: 277 HCC patients were enrolled. Of these, 22, 56, 147, and 52 fell into mALBI grades 1, 2a, 2b, and 3, while 131, 85, and 60 had HCC BCLC A, B, and C. 38 (15.6%) participants had HRV. The AUROC of the ALBI score and platelet for predicting HRV were 0.755 and 0.738. On multivariate analysis, platelet ≤150,000 /µL and mALBI grade 1 or 2a and platelet > 150,000/µL showed significant association with HRV in HCC. Moreover, HCC patients with mALBI grade 1 or 2a and platelet > 150,000/µL may avoid EV surveillance.

Conclusion: HRV was associated with mALBI grade and platelet at 150,000/µL. A pilot survey with 993 respondents found that 52.7% of those who had hepatitis virus testing during health check-ups had forgotten their history of testing.

Results: In the three nationwide surveys (responses from 23,720, 10,203, and 8,810 individuals), HBV and HCV recognized testing rates remained steady (17-20% for HBV, 15-18% for HCV). However, the testing rates including unrecognized testing increased by more than 10% from 2011 to 2017 (HBV: 58.4%, 71.0%, 71.1%; HCV: 48.0%, 61.6%, 59.8%). A pilot survey with 993 respondents found that 52.7% of those who had hepatitis virus testing during health check-ups had forgotten their testing history. Adjusting the nationwide survey based on this proportion, testing rate at 2020 reached 85.5% for HBV and 76.4% for HCV.

Conclusions: In Japan, 76.4-85.5% of the general population has already undergone hepatitis virus testing. The WHO’s elimination goal of over 90% of infected individuals getting tested is likely almost achieved.
and their littermate wild-type (WT) controls (Nogo-Bfl/fl) were fed a high-fat diet (HFD, 60% kcal% fat) for three months, followed by maltose or ethanol gavage (5g/kg weight). We found that Aldo-keto reductase family 1 member B8 (Akr1b8), the NAD(P)H-dependent oxidoreduction of various carbonyl compounds, was significantly downregulated in the liver of AFL group mice. Moreover, we found that there were fewer lipids in the liver of Akr1b8 knockout AFL group by oil red O staining, and it was due to the hepatocyte injury identified by Ki67 levels in different groups. Further liver tissue RNA transcriptomic of two groups revealed that there were several differently expressed genes enriched in alcohol metabolism-related pathways and lipid metabolism-related pathways. To verify these results, western blot was employed and the expression levels of lipid catabolism enzymes, including PPAR-γ and SCD1, were down-regulated in the KO-AFL group, suggesting that there were fewer lipids needed to be catabolized. Taken together, these results indicate that AKR1B8 is a potential therapeutic target of ALD.

AKR1B8 deficiency prevents the progression of alcoholic liver disease in mouse model

Yanfei Lang1, Jing Ning1, Shi gang Ding1, Fengmin Lu2

1 Peking University Third Hospital Beijing China, 2 Department of Microbiology & Infectious Disease Center, School of Basic Medical Sciences, Peking University Beijing China

Alcoholic liver disease (ALD) is a major cause of chronic liver disease, which causes an extremely severe healthcare burden worldwide. Alcoholic fatty liver (AFL), an early stage of ALD progression, is a clinically important spectrum of alcohol-related fatty liver disease (ALD). Presently, there is no approved drug for ALD. To explore the potential therapeutic target of AFL, we constructed a Lieber Decarli diet-induced AFL mouse model and analyzed the RNA transcriptomic of liver tissues. We found that Aldo-keto reductase family 1 member B8 (Akr1b8), the NAD(P)H-dependent oxidoreduction of various carbonyl compounds, was significantly downregulated in the liver of AFL group mice. Further, we found that there were fewer lipids in the liver of Akr1b8 knockout AFL group by oil red O staining, and it was due to the hepatocyte injury identified by Ki67 levels in different groups. Further liver tissue RNA transcriptomic of two groups revealed that there were several differently expressed genes enriched in alcohol metabolism-related pathways and lipid metabolism-related pathways. To verify these results, western blot was employed and the expression levels of lipid catabolism enzymes, including PPAR-γ and SCD1, were down-regulated in the KO-AFL group, suggesting that there were fewer lipids needed to be catabolized. Taken together, these results indicate that AKR1B8 is a potential therapeutic target of ALD.
Background: The impact of ALDH2 rs671 polymorphism as predictors of clinical prognosis in alcohol-related hepatocellular carcinoma (HCC) after hepatectomy remains largely unknown.

Methods: This prospective cohort study enrolled 238 alcohol-related HCC patients who underwent hepatectomy from 2011 to 2022 at the E-Da Hospital, I-Shou University, Kaohsiung, Taiwan. Data analyses were finalized on October, 2023. Alcohol intake was defined as consuming over 20 g of ethanol each day for at least 5 years. ALDH2 rs671 polymorphism was analyzed. The primary endpoint was HCC recurrence and overall mortality.

Results: 196 (82.4%) were men and the mean (SD) age was 62.3 (10.2) years. HCC recurrence occurred in 70 patients, and 64 patients died. The cumulative incidences of HCC recurrence and mortality after resection in all patients were 40.6% and 37.7%, respectively. The ALDH2 rs671 polymorphism is significantly associated with HCC recurrence and mortality. The cumulative incidences of HCC recurrence and mortality were significantly higher in patients with the ALDH2 rs671 genotype GA/AA than in those with the ALDH2 rs671 genotype GG. In Cox proportional analyses, the ALDH2 rs671 genotype GA/AA and AST ≥ 40 IU/L were significantly associated with increased HCC recurrence (HR:2.66, 95% CI: 1.59-4.43, P<0.001; and HR: 1.93, 95% CI: 1.18-3.17, P=0.009). Furthermore, the ALDH2 rs671 genotype GA/AA (HR: 2.02, 95% CI: 1.17-3.49, P=0.012) and age ≥ 65 years-old (HR: 1.67, 95% CI: 1.01-2.78, P=0.048) were significantly associated with increased mortality.

Conclusion: ALDH2 rs671 genotype GA/AA is significantly associated with worse clinical prognosis in alcohol-related HCC patients who underwent hepatectomy.

JPHX formula treated acute ALD in mice by regulating the metabolism of bile acids via gut-liver axis

Yue Chen1, 2, Hening Chen1, 2, Wenying Qi1, 2, Gang Wang1, 2, Yuyong Jiang4, Xiaobin Zao1, 2, 3

1Dongzhimen Hospital of Beijing University of Chinese Medicine, Beijing, China, 2Institute of Liver Diseases, Dongzhimen Hospital, Beijing University of Chinese Medicine, Beijing, China, 3Key Laboratory of Chinese Internal Medicine of Ministry of Education and Beijing, Dongzhimen Hospital, Beijing University of Chinese Medicine, Beijing, China, 4Beijing Ditan Hospital, Capital Medical University Beijing, China

Background: Effective pharmacotherapies of alcohol-related liver disease (ALD) are still lacking. JianPiHuoXue (JPHX), as a traditional Chinese medicine, has shown a therapeutic effect on ALD in clinical practice. Here, we aimed to reveal the mechanism of JPHX in the treatment of ALD.

Method: The mice acute ALD model was established by a persistent alcohol diet, and JPHX was given by intragastric administration. The detection of serological indicators and histopathological examination of liver and intestine tissues were performed. Meanwhile, non-target metabolomics (NTM) of liver tissues, and 16S ribosomal DNA sequencing (16S seq) of gut microbiota were used to investigate the mechanism of JPHX on ALD.

Results: Compared with the model, the intervention of JPHX significantly reduced serum levels of ALT and AST, alleviated hepatic steatosis, and restored the integrity of the intestinal structure. In non-target metabolomics, the Kyoto Encyclopedia of Genes and Genomes pathway enrichment analyses of differentially expressed metabolites between groups showed that JPHX may affect Primary bile acid biosynthesis and Glutathione metabolism pathways. In the gut microbiota analyses, the results of 16S seq showed that at the genus level, the JPHX treatment mainly increased the content of norank_f_Muribaculaceae, unclassified_f_Lachnospiraceae and so on, mainly decreased the content of Monoglobus and Escherichia-Shigella.

Conclusion: JPHX could effectively restore the liver and intestine injury caused by alcohol in acute ALD mice. These effects may be achieved by regulating the gut-liver axis, mainly in the metabolism of bile acids.

TFR2 p.A75V mutation aggravates liver iron overload in alcoholic liver disease via ERK pathway

Chao Xie1, Yingying Liu1, Xiaoming Wang1, Wei Zhang1, Xiaofan Wang1, Tianhui Liu1, Ping Wang1, Lin Liu1, Xu Fan1, Jidong Jia1, Xiaojuan Ou1, Anjian Xu2, Min Cong3

1Liver Research Center Beijing Friendship Hospital, Capital Medical University 95 Yong-An Road, Xicheng District Beijing, China, 2Experimental and Translational Research Center, Beijing Friendship Hospital, Capital Medical University Beijing, China

Background: Liver iron overload is commonly observed in individuals with advanced alcoholic liver disease (ALD). Genetic factors may play a role in the progression of ALD. We aimed to investigate the involvement of hemochromatosis-related genes in liver iron deposition among ALD patients.

Methods: We analyzed clinical data from 97 ALD patients and sequenced exons of HFE, HJV, HAMP, TFR2 and SLC40A1 in 43 patients. We evaluated the severity of iron overload in ALD mice by measuring serum iron metabolism indices, liver iron quantification, and liver iron staining. We examined the effects of TFR2 p.A75V on HAMP induction and its underling mechanism in vivo and in vitro.

Results: ALD patients with liver iron overload had worse liver function and prognosis scores compared to those without iron overload. We identified a potential functional mutation, TFR2 p.A75V, in ALD patients with iron overload. We established a new mouse model of ALD with liver iron overload. After administering recombinant AAV carrying the wild-type TFR2 gene, we observed a significant reduction in iron deposition in hepatocytes. However, the TFR2 p.A75V mutation did not alleviate iron overload in hepatocytes as the wild-type TFR2 did. The TFR2 p.A75V mutation may affect HAMP induction of iron by disrupting the ERK pathway, partially due to abnormal localization of the TFR2 protein in the cytoplasm.

Conclusion: TFR2 p.A75V mutation in ALD may reduce the sensitivity of hepatocytes to iron stimulation in vivo and in vitro by inhibiting the expression of HAMP through the ERK pathway, thereby aggravating iron overload.

Impact of alcoholic cirrhosis on development of renal insufficiency post-liver transplantation

George Lau1, 2, Dali Zhang3, Xi He1, Yudong Wang1, Gregory Cheng1, Jing Chen1, Hui Ren1, Zhenwen Liu2

1Humanity and Health Medical Group Hong Kong, Hong Kong, 2Senior Department of Hepatology, Fifth Medical Center of Chinese PLA General Hospital Beijing, China, 3JIC School of Public Health and Primary Care, Faculty of Medicine, Chinese University of Hong Kong, Hong Kong SAR, China
Objectives: Renal insufficiency is a common complication of liver transplantation (LT) and a risk factor for transplant related mortality. We aim to explore the impact of pre-LT alcoholic cirrhosis on development of post-LT renal insufficiency.

Methods: This retrospective study enrolled adult patients who had LT from January 2015 to January 2019 at a referral hospital. Patients were categorized into alcoholic cirrhosis and non-alcoholic liver disease groups. The incidence of chronic renal insufficiency, defined as creatinine >97 umol/L / >115 umol/L for female / male, persisting for >3 months post-transplant, was compared between two groups. Multivariate logistic regression was performed to explore the risk factors for renal insufficiency.

Results: A total of 139 consecutive patients who had LT were recruited (78.3% male, median age 47.46 years), among which 38 had alcoholic cirrhosis and 101 had non-alcoholic liver disease. Renal insufficiency prevalence was 20.14% overall, higher in alcoholic cirrhosis (34.2%) than non-alcoholic disease (14.9%) patients (P=0.027), with a relative risk of 2.30 (95%CI 1.21-4.38). After adjustment for confounding factors, alcoholic cirrhosis (OR=0.03, 95%CI 1.07, 15.19, P=0.040), male sex (OR=0.13, 95%CI 0.04, 0.51, p=0.003), and low tacrolimus trough concentration (reduced dosage due to renal insufficiency, cutoff values 4.75 ng/mL (OR=0.68, 95%CI 0.51, 0.89, p=0.001) were the independent factors associated with renal insufficiency.

Conclusion: Alcoholic cirrhosis independently increases the risk of chronic renal insufficiency after liver transplantation. Close monitoring of tacrolimus concentration is crucial for individuals with alcoholic cirrhosis post-LT.

Alcohol consumption patterns among various presentations of alcoholic liver disease in South Asians

Sawan Bopanna1, Charu Sharma1, Pallavi Garg1, Richa Bhargava1, Kaushal Madan1

1Max Superspeciality Hospital,Saket, New Delhi New Delhi India

Background and Aim: Alcohol consumption patterns vary between spectrum of alcoholic liver disease(ALD). Few studies compare drinking patterns with varied presentations of ALD among South Asians. We compared patterns of alcohol consumption among ALD with acute on chronic liver failure (ACLF), decompensated cirrhosis (D CLD) and alcoholic steatohepatitis (ASH)

Methods: Patients presenting with ALD from August to November 2022 included. Data regarding patterns of alcohol consumption collected using patient filled questionnaires filled in presence of family members and treating physician. Comparison of various parameters related to alcohol consumption between D CLD, AH/ACLF and ASH done using SPSS

Results: 30 ALD patients included. Median age 48(31-63) with 89.7% males with no significant difference in demographic features. Dose consumed during single binge measured in units (1 unit = 30 ml of whisky) was significantly higher in AH/ACLF group in comparison to other groups, 15(2-36) vs 7(3-15) and 10(5-10). Median duration of consumption in months 154(2-360), 90 (3-480),192(72-360) among AH/ACLF,D-CLD and ASH and difference was not significant. Frequency of binges,snacking, make and type of liquor did not show difference between the 3 groups

Conclusion: Though duration of alcohol intake was similar,AH/ACLF was associated with a higher dose of alcohol intake each time within same duration of drinking. Patients with intake of cirrhotic doses of alcohol, albeit in lower amount each time over a similar period of time presented with a D CLD or alcoholic steatohepatitis. Observation of such patterns in larger cohorts may help identify those patients with alcoholism likely to present with AH/ACLF

Addressing ARLD and AUD with an innovative hepatology nurse-led alcohol reduction program

Mikaela Daniells1, Brooke Gaggins1, Sarah Higgins1, Alicia Cross1, Andrew Sloss1, Angela Copley1, Teraha Wickremeratne1, James O’Beirne1 2, Rohit Gupta1

1SCUH Birtinya Australia, 2University of the Sunshine Coast Sippy Downs Australia

Background: Alcohol-related liver disease (ARLD) is a major under-funded and often neglected area of healthcare. Liver clinics with an integrated focus on addiction have improved outcomes. However, currently, Alcohol Use Disorder medications and psychological services are underutilised by Hepatologists. By establishing a pilot hepatology nurse-led alcohol reduction program, this study aims to address gaps in the current care model for patients with ARLD.

Methods: Patients were enrolled through the liver clinic at Sunshine Coast University Hospital, a tertiary Australian hospital. Seventeen patients were referred to the Pilot Hepatology Alcohol Reduction Program, for which ten patients elected to proceed with the program. Patients completed a 3-month program with two weekly follow-ups with an individualised patient-centred approach to address AUD, with titration and adherence to medications, psychological support including motivational counselling with the option of concurrent psychology assessments.

Results: All patients had ARLD, with 80% diagnosed with cirrhosis. At four weeks, the standard drinks per week reduced from 91.35 [CI 67.72-114.98] to 20.3 [CI 10.15-30.45] p-value <0.01. 70% of patients utilised AUD medications through this clinic, and 50% underwent formal psychology reviews.

Conclusion: Through a nurse-led clinic, patients achieve a significant reduction in alcohol intake and improvement in the utilisation of medications and psychological services.

Alcohol consumption and the risk of liver disease: a nationwide, population-based study

Yang Hyun Baek1, Sang Young Han2, Yeo Wool Kang1, Minkook Son1, Sang Yi Moon1

1Dong-A University College of Medicine Busan South Korea, 2On hospital Busan South Korea

Introduction: Although most patients with alcohol-related liver disease (ALD) have a history of prolonged and heavy drinking, there is no clear threshold defining the level of alcohol consumption that leads to ALD. We aimed to evaluate the correlation between average alcohol consumption and the risk of liver disease.

Materials and methods: Using the Korean National Health Insurance database, we identified participants who underwent a health-screening program. The primary outcome was to determine the incidence of newly diagnosed liver-related diseases during the observation period and compare the incidence of liver-related diseases among non-drinkers and drinkers based on the amount of alcohol consumption.
Results: A total of 53,006 patients were enrolled. The participants were divided into five groups: no alcohol, 1st quartile, 2nd quartile, 3rd quartile, and 4th quartile. The corresponding number of glasses of alcohol consumed per week for each quartile (Q1, Q2, Q3, and Q4) was labeled 0 ± 1.1 standard units, 1.8 ± 1.9 standard units, 4.9 ± 3.3 standard units, and 18.4 ± 3.0 standard units, respectively. Compared with non-drinkers, the risk of liver-related diseases was found to be higher in Q1 drinkers (adjusted hazard ratio [aHR], 1.09; 95% CI, 0.90-1.33), Q2 drinkers (aHR, 1.10; 95% CI, 0.91-1.32), Q3 drinkers (aHR, 1.33; 95% CI, 1.11-1.59), and Q4 drinkers (aHR, 1.47; 95% CI, 1.24-1.75).

Conclusions: We report that our study has shown that drinking more than 11.5 ± 3.3 standard units/week (92 ± 26.4 g/week) significantly increases the risk of developing liver-related diseases.

Secular trend of disease burden of alcoholic hepatitis in region endemic with chronic viral hepatitis

Vicki Wing-Ki Hui1, Terry Cheuk-Fung Yip1, Jimmy Che-To Lai2, Vincent Wai-Sun Wong3, Grace Lai-Hung Wong3, Robert John Wong4

1Department of Medicine and Therapeutics, Medical Data Analytics Centre (MDAC), Institute of Digestive Disease Hong Kong Hong Kong, 2VA Palo Alto Healthcare System and Stanford University School of Medicine Palo Alto United States of America

Objective: Alcoholic hepatitis is a relatively uncommon in Hong Kong, a city endemic with viral hepatitis. With many bars and restaurants shut down during COVID-19 restrictions in 2020 to 2022, off-premise sales of alcohol soared and may lead to increase burden of alcoholic hepatitis. We aimed to evaluate the secular trend of the disease burden of alcoholic hepatitis over the last decade in Hong Kong.

Methods: This was a territory-wide cohort study of consecutive patients with alcoholic hepatitis from January 2010 to June 2022. Alcoholic hepatitis was defined with at least one of the relevant diagnosis codes (ICD-9 571.1 or ICD-10 K70.10, K70.11) together with at least three of the following laboratory criteria: 1) ALT or AST > 50 IU/L; 2) AST:ALT ratio > 2; 3) INR > 2; and/or 4) bilirubin > 3.0 mg/dL.

Results: 943 patients were diagnosed with alcoholic hepatitis; their mean age was 51.1±12.7 years; 89.5% were male. The incidence rates of alcoholic hepatitis fluctuated over the last decade, with a clear increase in the first two years of COVID-19 pandemic (2020-2021) and then dropped in 2022-2023 (2.72-2.83 per 100,000 population), when compared to the baseline (0.90-1.33).

Conclusions: We report that our study has shown that drinking more than 11.5 ± 3.3 standard units/week (92 ± 26.4 g/week) significantly increases the risk of developing liver-related diseases.

Impact of Smoking on Alcoholic Liver Disease and Mortality: Compounding Hazards

Jeong-Ju Yoo1, Chan Jin Yang1, Jin Wook Park1, Dong Hyeon Lee2, Jae Young Jang3, Log young Kim4, Gab Jin Cheon5

1Soonchunhyang University Bucheon Hospital Bucheon South Korea, 2Seoul Metropolitan Government Seoul National University Boramae Medical Center Seoul South Korea, 3Soonchunhyang University Seoul Hospital Seoul South Korea, 4National Health Insurance Service Wonju South Korea, 5Gangneung Asan Hospital Gangneung South Korea

Background: The purpose of this study is to address the critical public health issue of alcoholic liver disease, focusing on its trends, incidence and outcomes.

Methods: National Health Insurance Service claims data and health check-up information from 2011 to 2017 was utilized. Population’s overall drinking amount and the incidence of alcoholic liver disease was calculated based on ICD-10 diagnosis codes.

Results: There has been an overall increase in the rates of regular drinking (49.3% to 51.1%), moderate drinking (15.4% to 16.4%), and stable proportion of high-risk drinking (14.9% to 14.7%) between 2011 and 2017. The incidence rate of alcoholic liver disease increased in proportion to the amount of alcohol (moderate drinker 0.15%, high risk drinker 0.93%) and relatively higher in men than women. There is a decreasing trend in alcoholic fatty liver disease (26% to 22%) but an increase in alcoholic cirrhosis (16% to 26%). Both men and women show an increasing trend in the progression from alcoholic liver disease to cirrhosis over a 3-year follow-up period, with a higher increase rate observed in women. Additionally, medical costs for patients are rising annually, and patients with alcoholic liver disease require more hospitalization and outpatient care compared to the control. However, there was a decreasing trend in the co-diagnosis of alcohol use disorders since 2016 (9.43% to 7.98%).

Conclusion: This study underscores the growing health and social challenges posed by alcoholic liver disease. The rising rates of severe liver disease forms and associated costs indicate an ongoing public health concern.

Impact of Smoking on Alcoholic Liver Disease and Mortality: Compounding Hazards

Jeong-Ju Yoo1, Chan Jin Yang1, Jin Wook Park1, Dong Hyeon Lee2, Jae Young Jang3, Log young Kim4, Gab Jin Cheon5

1Soonchunhyang University Bucheon Hospital Bucheon South Korea, 2Seoul Metropolitan Government Seoul National University Boramae Medical Center Seoul South Korea, 3Soonchunhyang University Seoul Hospital Seoul South Korea, 4National Health Insurance Service Wonju South Korea, 5Gangneung Asan Hospital Gangneung South Korea

Background: The purpose of this study is to address the critical public health issue of alcoholic liver disease, focusing on its trends, incidence and outcomes.

Methods: National Health Insurance Service claims data and health check-up information from 2011 to 2017 was utilized. Population’s overall drinking amount and the incidence of alcoholic liver disease was calculated based on ICD-10 diagnosis codes.

Results: There has been an overall increase in the rates of regular drinking (49.3% to 51.1%), moderate drinking (15.4% to 16.4%), and stable proportion of high-risk drinking (14.9% to 14.7%) between 2011 and 2017. The incidence rate of alcoholic liver disease increased in proportion to the amount of alcohol (moderate drinker 0.15%, high risk drinker 0.93%) and relatively higher in men than women. There is a decreasing trend in alcoholic fatty liver disease (26% to 22%) but an increase in alcoholic cirrhosis (16% to 26%). Both men and women show an increasing trend in the progression from alcoholic liver disease to cirrhosis over a 3-year follow-up period, with a higher increase rate observed in women. Additionally, medical costs for patients are rising annually, and patients with alcoholic liver disease require more hospitalization and outpatient care compared to the control. However, there was a decreasing trend in the co-diagnosis of alcohol use disorders since 2016 (9.43% to 7.98%).

Conclusion: This study underscores the growing health and social challenges posed by alcoholic liver disease. The rising rates of severe liver disease forms and associated costs indicate an ongoing public health concern.
Additionally, smoking significantly increased the 3-year mortality rate in the high-risk drinker group (0.64% vs. 0.49%), and the risk increased significantly in women (RR men 1.18, women 1.95).

**Conclusion:** Smoking worsens the incidence and mortality of alcoholic liver disease in high-risk drinkers. In particular, because the risk increases more for women than for men, smoking cessation education for female drinkers is important.

**Neutrophil-to-Lymphocyte Ratio and Infection in Patients with Severe Alcoholic Hepatitis**

ping zhu¹

¹Department of Hepatology and Gastroenterology, Tianjin Third Central Hospital Tianjin China

**Background & aims:** Severe alcoholic hepatitis (SAH) may appear liver failure or decompensation, with infection and high-short-term mortality. We assessed the predictive value of blood neutrophil/lymphocyte ratio (NLR) for infection in patients with SAH.

**Methods:** The patients with SAH were divided into infected group and non-infected group. The indexes in the two groups were compared, and the relationship between NLR and infection was clarified by the generalized additive model. If the curve fitting result between the two groups was non-linear. We analyzed the threshold effect by the piecewise regression model.

**Results:** The clinical data of 143 patients with SAH were collected. According to the presence or absence of infection, we divided the patients into the non-infected group (n = 69) and the infected group (n = 74). When NLR < 13.37, the risk of infection increased by 15% for each 1.00 increase in NLR, OR = 1.15, 95% CI (1.04, 1.27), P = 0.0065. NLR was positively correlated with the risk of infection in a certain range. **Conclusions:** NLR was an indicator to predict infection in patients with SAH.

**Keywords:** alcoholic hepatitis; neutrophil to lymphocyte ratio; prognosis; infection

**Genetic Analysis Of The Composition Of Fatty Acid In Diagnosis and Therapy of Alcoholic Liver Disease**

Ramalah Ramlah¹, Haerani Haerani²

¹Universitas Sulawesi Barat Majene Indonesia, ²STIKes Bina Bangsa Majene Majene Indonesia

**Introduction:** The large number of microbiota that inhabit the human digestive system have an important role with the immune system. Microbiota produce a wide variety of metabolites, including short chain fatty acids. Alcohol-related liver disease is liver damage due to excessive and long-term alcohol consumption. This study aims evaluate the compositions of short chain fatty acid producing gut microbiota in diagnosis and therapy of alcoholic liver disease.

**Method:** Data obtained from 29 sequences of the compositions of short chain fatty acid producing gut microbiota of alcoholic liver disease on secondary data form on https://www.ncbi.nlm.nih.gov/. The phylogeny analysis was constructed with UPGMA method using MEGA7.0 software.

**Result:** The optimal tree with the sum of branch length = 28.01713153 is shown. The tree is drawn to scale, with branch lengths in the same units as those of the evolutionary distances used to infer the phylogenetic tree. Genetic variation comes from mutations in genetic material, migration (gene flow), and changes in gene composition through sexual reproduction. Variations also come from the exchange of specific genes. Genetic diversity is the key in character improvement programs for specific genes. This is due to the maximization of genetic acquisition of certain traits. High genetic variation will produce adaptive traits.

**Conclusion:** Genetic Variation of The compositions of short chain fatty acid producing gut microbiota in diagnosis and therapy of alcoholic liver disease have high degree of genetic variability. This information is important for future genetic improvement.

**Keywords:** Genetic Variation, Short Chain Fatty Acid, Gut Microbiota, Alcoholic Liver Disease
Conclusion: Thrombocytopenia and leukopenia are common complications of alcoholic liver cirrhosis (ALC) and are associated with an increased risk of bleeding, infection, and mortality. We aimed to evaluate the therapeutic effect of leucogen, a cysteine derivative that increases platelet and white blood cell (WBC) counts in patients with ALC.

Methods: A total of 413 patients with ALC who had thrombocytopenia (platelet < 100×10^9/L) and/or leukopenia (WBC < 4.0×10^9/L) were enrolled in this retrospective study, the patients were treated with leucogen (20mg, 3 times per day) or not. The primary endpoint was an increase in platelet or WBC count of ≥5% from baseline. Propensity score matching (PSM) was utilized to minimize the impact of selection bias.

Results: Among the 320 patients included in the final analysis after PSM, patients receiving leucogen had significantly higher proportions of platelet increase (46.9% vs. 32.5%, p = 0.012), WBC increase (50.0% vs. 36.2%, p = 0.018) and both PLT and WBC increase (28.1% vs. 15.6%, p = 0.010). The leucogen group exhibited superior fold increases in platelet count (OR 1.833; 95% CI 1.164-2.885; p = 0.009) and WBC count (OR 1.759; 95% CI 1.125-2.750; p = 0.013) compared to the non-leucogen group. Subgroup analysis revealed that patients with baseline factors such as age <60 years, ALT <40 U/L, and AST <40 U/L showed favorable treatment outcomes.

Conclusions: Leucogen is an effective treatment for thrombocytopenia and leukopenia in patients with alcoholic liver cirrhosis.

Primary sclerosing cholangitis (PSC) is an autoimmune cholangiopathy characterized by chronic inflammation of the biliary epithelium and periductal fibrosis, with no curative treatment available and liver transplantation inevitable for end-stage patients. Human placental mesenchymal stem cell (hpMSC)-derived exosomes (ExoMSC) have demonstrated the ability to anti-fibrosis, inhibit collagen production in autoimmune liver disease and possess immunomodulatory properties. Here, we prepared hpMSC-derived exosomes (ExoMSC) and further investigated the anti-fibrotic effects and detailed mechanism on PSC. Results show that ExoMSC ameliorated liver fibrosis in PSC mice (Mdr2Δ/Δ) with significant collagen reduction in the preducal area where Th17 differentiation was inhibited as demonstrated by RNAseq analysis, and the percentage of CD4+ IL-17A+ T cells was reduced both in ExoMSC-treated Mdr2Δ/Δ mice (Mdr2Δ/Δ-Exo) in vivo and ExoMSC-treated Th17 differentiation progressed in vitro. Furthermore, ExoMSC improved the hypersecretory phenotype and intercellular interactions in the hepatic Th17 microenvironment by regulating Perk/Chop signaling as supported by multilecellular organoids. Thus, our data provide mechanistic and therapeutic insights into the role of ExoMSC in liver fibrosis of PSC or Th17-related diseases.

Primary sclerosing cholangitis (PSC) is a rare, cholestatic liver disease characterized by chronic inflammation of the biliary epithelium and periductal fibrosis, with no curative treatment available and liver transplantation inevitable for end-stage patients. Human placental mesenchymal stem cell (hpMSC)-derived exosomes (ExoMSC) have demonstrated the ability to anti-fibrosis, inhibit collagen production in autoimmune liver disease and possess immunomodulatory properties. Here, we prepared hpMSC-derived exosomes (ExoMSC) and further investigated the anti-fibrotic effects and detailed mechanism on PSC. Results show that ExoMSC ameliorated liver fibrosis in PSC mice (Mdr2Δ/Δ) with significant collagen reduction in the preducal area where Th17 differentiation was inhibited as demonstrated by RNAseq analysis, and the percentage of CD4+ IL-17A+ T cells was reduced both in ExoMSC-treated Mdr2Δ/Δ mice (Mdr2Δ/Δ-Exo) in vivo and ExoMSC-treated Th17 differentiation progressed in vitro. Furthermore, ExoMSC improved the hypersecretory phenotype and intercellular interactions in the hepatic Th17 microenvironment by regulating Perk/Chop signaling as supported by multilecellular organoids. Thus, our data provide mechanistic and therapeutic insights into the role of ExoMSC in liver fibrosis of PSC or Th17-related diseases.
Cellular senescence-triggered dysfunction of hepatocyte aggravates autoimmune liver injury

Jian Chen1, Xinhao Hu1, Tianchen Lan2, Xiao Xu1

1Zhejiang University Hangzhou China, 2Zhejiang Chinese Medical University Hangzhou China

Background: Autoimmune hepatitis (AIH) is an inflammatory liver disease characterized by immune cell-mediated autoimmune response against liver autoantigens. However, little is known about the role of hepatocyte senescence in AIH pathogenesis.

Methods: A novel murine AIH model was established by inhibiting hepatocyte cytokinesis. Cellular senescence was assessed through SA-β-Gal staining and senescent associated secretory phenotype assay. Biochemical and histopathological experiments were performed to detect the hepatic function and liver injury in AIH model. scRNA sequencing was carried out to explore the cellular transition and transcriptomic profile of hepatocyte in AIH. Therapeutically, the efficacy of senolytic treatment (dasatinib plus quercetin) was also investigated in murine AIH model.

Results: Inhibition of cytokinesis induced senescent phenotype in hepatocyte, demonstrating as cell cycle arrest, morphological changes as well as senescent associated secretory phenotype. The liver with senescent hepatocytes exhibited AIH features, including increased ALT and AST levels, presence of autoantibodies and severe interface hepatitis and fibrosis on liver histology. scRNA sequencing analysis revealed an unique hepatocyte cluster with senescent characteristic in AIH liver, which strongly communicated with CD4+ T cell and CD8+ T cell. Unexpectedly, when the AIH mice were treated with senolytic drugs, the liver injury was dramatically alleviated. The increased hepatocyte senescence was also found in AIH patients compared with healthy persons and the senescence proportion was correlated with clinicopathological features.

Conclusions: This study established a novel murine AIH model and revealed the critical role of hepatocyte senescence in AIH pathogenesis. The senolytic treatment is highlighted as a promising therapeutic strategy for AIH.

MSC-EV protects against immunological liver injury by suppressing ferroptosis via Nrf2/GPX4 axis

Xiaoli Fan1, Mengyi Shen1, Leyu Zhou1, Jingping Liu1, Li Yang1

1West China hospital, Sichuan University Chengdu China

Ferroptosis plays an important role in the pathogenesis of various liver diseases, yet it has rarely been investigated in human autoimmune hepatitis (AIH). This study is meant to explore the protective effect and mechanism of extracellular vesicles of mesenchymal stem cells (MSC-EVs) on ferroptosis and excessive inflammation of immunological liver injury (ILI). We found that inflammation associated hepatocytes ferroptosis occurred in ILI mice, whereas deferoxamine attenuated liver injury. In ILI mice, MSC-EVs might reduce hepatocytes ferroptosis and subsequently improve liver injury, while KEGG pathways enrichment analysis also validated that ferroptosis inhibition was involved in the underlying therapeutic mechanisms. Besides, further GPX4 inhibition experiments revealed that MSC-EVs alleviated inflammatory response induced ferroptosis via upregulating GPX4 in vitro. Meanwhile, MSC-EVs could increase the expression of Nrf2 and Nrf2 inhibition alleviated the effects of MSC-EVs. Transwell assay revealed that MSC-EVs could prevent the recruitment and chemotaxis of macrophages induced by ferroptotic hepatocytes. Moreover, we found that there was a significant correlation between levels of circulating 4-HNE and transaminases and treatment response, while over-activation of ferroptosis was revealed in hepatocytes in AIH patients. In conclusion, MSC-EVs could ameliorate inflammatory injury in ILI by suppressing hepatocytes ferroptosis via the Nrf2/GPX4 signaling pathway.
Targeting monocytes via CCL2/CCR2 axis in autoimmune hepatitis by macrophage-derived exosomes

Xiaoli Fan1, Ruiqi Wu1, Fan Yang1, Jingping Liu1, Li Yang1
1West China hospital, Sichuan University chengdu China

Background: Autoimmune hepatitis is a serious chronic liver disease with immune disorders, histological lesions and liver dysfunction, with a gradually increasing prevalence. Yet the cellular and molecular mechanisms of immune dysregulation in AIH are poorly understood.

Methods: Using proteomic analysis, we comprehensively profiled the differentially expressed proteins and signaling pathways of liver during human AIH. Then, monocytes and macrophage from blood and livers of AIH patients and controls were analyzed. The recruitment and polarization of monocyte-derived macrophages in AIH and the mechanism of CCL2/CCR2 axis activation were investigated by Concanavalin induced experimental AIH (EAH). The CCL2/CCR2 axis was blocked by CCL2 neutralizing antibody and CCR2 antagonist to determine its effect on AIH mice. Finally, M2 macrophage-derived extracellular vesicles (M2-EVs) were isolated and extracted as drug delivery tool of CCR2 antagonist, and its therapeutic effect on AIH mice was determined.

Results: Proteomic analysis took expression ratio (FC) > 1.5 times and P<0.05 as screening criteria, and a total of 1028 proteins were identified as increased or decreased. KEGG analysis suggested that differential expressed proteins were mainly associated with metabolic processes. The expression of mononuclear macrophage system marker proteins CD14, S100A9, CD163, CD68 and CD11b increased in the liver tissue of AIH patients as revealed by proteomic analysis and immunohistochemistry. The proportion of classical monocytes in peripheral blood of AIH was increased, which was positively correlated with the levels of ALT and AST of AIH patients. The co-localization analysis of liver tissue suggested that CCL2 originated from Kupffer cells (KC), and the expression of CCR2 increased after circulating monocytes infiltrated liver. The expression of M1 marker in AIH liver tissue increased. AIH mouse models suggest mobilization of inflammatory monocytes on the bone marrow-liver axis and spleen-liver axis. Blocking up of CCL2/CCR2 axis with CCL2 neutralizing antibody or CCR2 antagonist, respectively, alleviated liver injury in AIH mice, while recombinant CCL2 injection increased recruitment of inflammatory monocytes with bone marrow-liver axis and spleen-liver axis to liver, aggravating liver injury. CCR2 antagonist-M2-EV can target circulating mononuclear cells and activated mononuclear macrophages in the liver, respectively, to reduce liver injury in AIH mice.

Conclusion: AIH mediates the recruitment of inflammatory monocytes from bone marrow and spleen to liver through the CCL2/CCR2 axis, which can be inhibited by different methods to reduce liver inflammatory injury in AIH mice. M2-EVs delivers CCR2 antagonists targeting activated pro-inflammatory monocytes and hepato-splenic mononuclear macrophage system in the circulating pool, indicating that CCR2 antagonists-EVs could be a potential agent for liver and monocyte targeted therapy for AIH.

Bile multi omics provide molecular insight and classify signatures of carcinoma of gall bladder

NUPUR SHARMA1, Sadam H Bhat1, Babu Mathew1, Manisha Yadav1, Gaurav Tripathi1, Vasundhara Bindal1, Neha Sharma1, Sushmita Pandey1, Hami Hemati2, Deepika Bohra2, Rashmi Rana2, Sanyam Falari1, Vinnyendra Pamecha1, Jaswinder Singh Maras1
1Institute of Liver and Biliary Sciences Faridabad India, 2Department of Research, GRIPMER, New Delhi India, 3University of kentucky Lexington India

Carcinoma of the gall bladder (CAGB) has poor prognosis. Molecular analysis (proteome/metabolome) of bile could recapitulate changes associated with CAGB development and help in characterization of putative indicators for early CAGB diagnosis. Bile samples screened for proteomics-metabolomics signatures capable of early detection of cancer in GB anomalies. Analysis of training cohort (n=87) showed that bile of CAGB patients has distinct proteomic (217up- and 258 down-regulated; FC>1.5) and metabolomic (111 up- and 505 down-regulated; FC>1.5) phenotype as compared to Gallstone or HC (p<0.05,FDR<0.01). Partial least square discriminant analysis and unsupervised hierarchical-clustering segregated CAGB patients. CAGB bile was significantly enriched for proteins/metabolites linked to inflammation, and alternate energy pathways (pentose phosphate pathway, amino acid metabolism, lipid metabolism, and others). CAGB bile showed reduction of Proteins/metabolites associated to glycolysis, cholesterol metabolism, PPPAR, RAS, and RAP1 signaling glutathione, histidine, purine metabolism, oxidative phosphorylation, and others (p<0.05). Integration analysis revealed strong correlation (r>0.5, p<0.05) between significant proteins/metabolites and clinical parameters and showed alteration of pathways linked to lipid metabolism, platelet activation, amino acid metabolism, and others (p<0.05). Metabolite/protein signature-based probability of detection for CAGB was >90% (p<0.05) with AUC=0.94. Validation of top four metabolites panel: Toluene, 5,6-DHET, Creatine, and Phenyl acetaldehyde using five machine-learning algorithms in two separate cohorts (n=40; bile [test cohort 1] and paired plasma [test cohort 2]) showed accuracy (99%) and sensitivity/specificity (>98%) for CAGB detection. Conclusion: Bile proteome and metabolome alteration provides critical molecular understanding and outlines metabolomics panel which may offer universal utility for early detection of CAGB.

The analysis of risk factors for hepatocellular carcinoma in patients with autoimmune liver disease

Makiko Tanai1, Katsutoshi Tokushige1, Yuri Ogasawara1, Tomomi Kogiso1
1Tokyo Women's Medical University Shinjyuku-ku, Tokyo Japan

Aim: Autoimmune liver disease including primary biliary cholangitis (PBC) and autoimmune hepatitis (AIH) is rare as the cause of hepatocellular carcinoma (HCC) in Japan. However, the hepatocarcinogenesis in autoimmune liver disease is still unclear. Metabolic syndrome such as obesity or type 2 diabetes mellitus (DM) has been reported to increase the risk of HCC. Thus, we have conducted a study to clarify the clinical risk factors for developing HCC in patients with autoimmune liver disease.

Patients and Methods: We investigated 608 PBC patients (females; 86%, median age; 59 (21-85) and 314 AIH patient diagnosed (females 84% age 52 (19-86) as Japanese Criteria. We observed all 922 patients without HCC at the time of the initial diagnosis with PBC or AIH for a median of 9.4 years (0.3-35) to evaluate risk factors for the development of HCC.
**Results:** HCC newly developed in 57 patients. The cumulative appearance rate of HCC was 0.5% and 1.2% at the end of the fifth and tenth years by Kaplan-Meier analysis. Independent risk factors for HCC by Cox model were cirrhosis [hazard ratio (HR) 4.459, p = 0.005], higher age (HR 1.077, p = 0.014), male gender (HR 2.884, p = 0.027), and complicated DM (HR 1.538, p = 0.031).

**Conclusions:** The independent risk factors for HCC in patients with autoimmune liver disease were cirrhosis, age, male, and DM. Careful observation of patients with a high risk of HCC will improve the prognosis of patients with PBC or AIH.

**Low serum complement is common in autoimmune hepatitis and is related to high serum immunoglobulin G**

**Yi Shen**, **Jie Sun**, **Mengyi Shen**, **Li Yang**

1Department of Gastroenterology & Hepatology, Sichuan University-University of Oxford Huaxi Joint Centre for Gastrointestinal Cancer, Frontiers Science Center for Disease-Related Molecular Network, West China Hospital, Sichuan University Chengdu China

**Objective:** Complement could mediate immune response and inflammation in systematic immune diseases, but its role in autoimmune hepatitis (AIH) has not been clearly clarified.

**Methods:** We retrospectively collected 146 patients with diagnosis of AIH, systemic lupus erythematosus and other liver diseases were excluded. Biochemical tests were performed before treatment. In our hospital, normal range of complement 3 (C3) is 0.785-1.520 g/L, and C4 is 0.145-0.360 g/L. So, we defined C3 <0.785 g/L as low-C3 and C3 >1.520 g/L as high-C3, C4 <0.145 g/L as low-C4 and C4 >0.360 g/L as high-C4. The G grade (Scheuer score system) of inflammation of liver biopsy tissues were evaluated. Firstly, we analyzed the correlations between complement and transaminase (ALT and AST). Then, because guidelines recommended that immunoglobulin G (IgG) > 2x upper limit of normal (ULN) is an indicator of immunosuppressive therapy, so we divided patients into two groups according to IgG (≥2x ULN and >2x ULN) for further analysis. Also, we performed comparison between patients with different G grade (G1-G2 and G3-G4). Finally, because cirrhosis could lead to elevated serum IgG and low complement, we excluded patients with cirrhosis for further analysis.

**Results:** Eighty-three (56.8%) patients with low-C3 and 71 (48.6%) patients with low-C4. No patients had high-C3 and only one patient had high-C4. There were no significant correlations of C3 and ALT/AST (P=0.766, r=0.205; P=0.256, r=0.094, respectively). For C4, the correlations between it and ALT/AST were weak (P=0.001, r=-0.264; P=0.005, r=0.229). And we found that patients in IgG≥2x ULN group had lower serum complement than that in IgG≤2x ULN group [C3: 0.588±0.288 g/L, 0.770±0.25 g/L, P=0.001; C4: 0.116 (0.102, 0.129) g/L, 0.155 (0.122, 0.203) g/L, P<0.001]. In addition, 139 patients performed liver biopsy, patients in G3-G4 group had lower serum complement than that in G1-G2 group [C3: 0.712±0.265 g/L, 0.813±0.234 g/L, P=0.026; C4: 0.135 (0.106, 0.181) g/L, 0.167 (0.136, 0.216) g/L, P=0.003]. Sixty-seven patients were excluded because cirrhosis. Then, further comparison indicated that patients with low serum complement had higher IgG [low C3 vs non-low C3: 26.7 (20.0, 32.4) g/L vs 17.8 (16.3, 23.3) g/L, P=0.003; low C4 vs non-low C4: 26.6 (20.0, 33.5), 18.6 (16.0, 24.9), P=0.002]. But no matter for C3 or C4, percentages of G3-G4 were not significantly different between two groups [low C3 vs non-low C3: 15 (51.7%), 24 (51.1%), P=0.955; low C4 vs non-low C4: 13 (65.0%), 26 (46.4%), P=0.154].

**Conclusion:** Low serum C3/C4 was very common in AIH patients, and it was related to high serum IgG.

**Multi-omics reveal underlying mechanisms of drug-response in PBC/AIH variant syndrome**

**Fan Yang**, **Leyu Zhou**, **Yi Shen**, **Xianglin Wang**, **Xiaoli Fan**, **Li Yang**

1Department of Gastroenterology and Hepatology and Sichuan University-University of Oxford Huaxi Joint Centre for Gastrointestinal Cancer, West China Hospital, Sichuan University Chengdu China

**Background:** Primary biliary cholangitis (PBC) and autoimmune hepatitis (AIH) variant syndrome (VS) present a complex overlap of AIH features with PBC, creating challenges for clinical management. This study aims to elucidate the mechanisms underlying drug response in PBC/AIH VS by integrating whole-transcriptomics and metabolomics, complemented by cytokinomic analysis.

**Methods:** We performed whole-transcriptome sequencing on liver tissues from 10 PBC/AIH VS patients, categorizing them into good responders (GR) and poor responders (PR). Additionally, we conducted plasma metabolomics on 50 PBC/AIH VS patients, further divided...
into GR (n=20) and PR (n=30). A wide range of cytokines was quantified in the same plasma using bead-based immunoassay technology. Findings: Analysis identified 224 differentially expressed (DE) mRNAs, 189 DE long non-coding RNAs, 39 DE circular RNAs, and 63 DE microRNAs. Functional pathway analysis enriched in immune response and metabolic pathways. We constructed 256 lncRNA-miRNA-mRNA networks and 19 circRNA-miRNA-mRNA networks, offering insights into regulatory interactions. Furthermore, we detected eight cytokines significantly differing between the two groups, indicating correlations between Th1 and Th2, as well as Th17 and Treg subsets, and drug response.

Conclusion: This exploratory study enhances our understanding of drug response mechanisms in PBC/AIH VS through comprehensive whole-transcriptome analysis. It also unveils distinctions in metabolic and immune profiles between patient subgroups by integrating metabolomics and cytokinomics. These findings offer new perspectives for treatment of these patients.

Identification of High-Risk Group for Relapse in Autoimmune Hepatitis Patients
Takatoshi Nawa¹, Tomonori Ishida¹, Ryota Nakanishi¹, Shingo Maeda¹, Koshi Sunaga¹, Mina Kato¹, Haruki Akamatsu¹, Shuji Ishii¹, Masahiko Tsujii¹
¹Department of Gastroenterology, Higashiosaka-city Medical Center

Background and Aim: Autoimmune Hepatitis (AIH) is a relatively rare disease caused by an autoimmune disorder. While steroid therapy is effective in many cases, some cases have relapses during steroid tapering. In this study, we investigated the risk factors for relapse during steroid therapy in AIH patients.

Methods: We retrospectively analyzed 31 cases of AIH patients who started steroid therapy at our institution from October 2010 to April 2023. We defined the patients who had relapse before tapering prednisolone to a dosage of 5mg/day as Relapse group, while others as Remission group. Risk factors for relapse were analyzed by using logistic regression model.

Results: Among 31 cases, 26 kept being remission, while five had relapse. All cases of Relapse group were brought under control by the addition of azathioprine. Multivariate analysis showed only age was an independent risk factor for relapse (odds ratio = 0.85, 95% confidence interval (CI) = 0.728-0.992, p-value = 0.04). Relapses were observed only in younger group (< 66 years, n = 15). In that group, high International AIH Group (IAIHG) scores at pretreatment showed a significant trend as a risk factor in univariate analysis (odds ratio = 1.53, 95% CI = 0.943-2.490, p-value = 0.085). We defined high-risk group as the patients who were young (< 66 years) and had high IAIHG scores (> 15 points), and the relapse rate of that group was 66.7% (4/6 cases). Conclusion: AIH patients with both younger age and high IAIHG scores have a higher risk of relapse during steroid tapering.

Azathioprine on Risk of Extrahepatic Malignancy with Autoimmune Hepatitis: A Nationwide Claims Study
Sung Hwan Yoo¹, Jung Il Lee¹, Hyun Woong Lee¹
¹Gangnam Severance Hospital Seoul South Korea

Background and aims: Long-term immunosuppressive therapy in patients with autoimmune hepatitis (AIH) increases the risk of extrahepatic malignancy in addition to hepatocellular carcinoma. However, the risk of extrahepatic malignancy is unknown in Korean AIH patients. We aimed to evaluate the impact of azathioprine (AZT) treatment on extrahepatic malignancy risks.

Methods: We identified all persons diagnosed with AIH between 2008 and 2020. We included 8,280 patients with AIH, using the national claims data of the Health Insurance Review and Assessment Service (HIRA). The numbers of patients treated with and without AZT were 3,059 and 5,221, respectively. We estimated the cumulative risks of extrahepatic malignancy and hazard ratios (HRs) between patients treated with and without AZT.

Results: Among 8,280 patients, the mean age was 56.7±13.5 years, 84.3% were women, and the follow-up period was 49.8±43.1 months. The mean age and sex are not different between patients treated with and without AZT. However, the number of patients with diabetes was higher in patients treated with AZT (31.3% vs. 28.0%). The number of patients with liver cirrhosis was higher in patients treated without AZT (36.0% vs. 38.9%). At the time of diagnosis, 85.5% of patients with AZT and 30.0% of patients without AZT were treated with steroids for more than 90 days (P<0.001). The incidence of extrahepatic malignancy was 1.36 and 1.23 per 100 person-years in the patients treated with AZT and without AZT, respectively (P=0.685). After we adjusted for confounding by age, sex, diabetes, and liver cirrhosis, the HR was 1.09 (95% confidence interval 0.79-1.51, P=0.600).

Conclusion: The national claims data of HIRA did not show that AZT significantly increases the risk of extrahepatic malignancy among AIH patients.

Association of sarcopenia with treatment response and outcomes in non-cirrhotic PBC patients
Leyu Zhou¹, Bo Li², Yifeng Liu¹, Xianglin Wang¹, Yuxin Guo¹, Yan Yi Zheng¹, Qiaoyu Deng¹, Xiaoli Fan¹, Li Yang²
¹Department of Gastroenterology and Hepatology and Hepatology and Sichuan University-University of Oxford Huaxi Joint Centre for Gastrointestinal Cancer, Frontiers Science Center for Disease-related Molecular Network, West China Hospital, Sichuan University, ²Department of Radiology, West China Hospital, Sichuan University Chengdu China

Background: The prevalence of sarcopenia and its effects on the treatment outcomes of ursodeoxycholic acid (UDCA) in patients with non-cirrhotic primary biliary cholangitis (PBC) remains uncertain.

Aims: To investigate the prevalence of sarcopenia and its association with biochemical responses and clinical outcomes in non-cirrhotic PBC patients.

Methods: Between January 2009 and July 2022, consecutive PBC patients were retrospectively enrolled. Sarcopenia was assessed via pre-treatment CT or MRI scans at the L3 level. Baseline characteristics, response rate of UDCA treatment, liver-related adverse events, as well as the gene expression and protein level of C-reactive protein (CRP) and interleukin-6 (IL-6) were compared in patients with and without sarcopenia.
Autoimmune hepatitis - primary biliary cholangitis overlap syndrome

Chongqing Medical University Chongqing China, 2Department of

(AIH-PBC OS) is a rare disease with non-specific signs and symptoms. However, the exact role of sarcopenia in the progression and outcomes of PBC requires further investigation.

A Rare Case of Autoimmune Hepatitis-Primary Biliary Cholangitis Overlap Syndrome in a Filipino Adult

Katrina Nicole Mejia1, Celina Celeste Adraneda1

1Cardinal Santos Medical Center San Juan Philippines

Autoimmune hepatitis - primary biliary cholangitis overlap syndrome (AIH-PBC OS) is a rare disease with non-specific signs and symptoms. We report a case of a Filipino adult female presenting with one week history of abdominal pain, accompanied by malaise and jaundice. Laboratory tests revealed gamma glutamyl transferase (GGT) > 5 times upper limit of normal (ULN) and presence of anti-mitochondrial antibodies (AMA); alanine aminotransferase (ALT) activity > 5 times ULN and liver biopsy with moderate interface hepatitis. These parameters fulfilled two out of the three criteria each for the diagnosis of PBC and AIH, respectively, hence the diagnosis of AIH-PBC OS - AIH predominant was made. She was started on prednisone and ursodeoxycholic acid (UDCA). However, on dual energy X-ray absorptiometry (DEXA) scan, she was noted to have osteoporosis, hence prednisone was continued to be tapered and discontinued. Azathioprine was added (DEXA) scan, she was noted to have osteoporosis, hence prednisone was continued to be tapered and discontinued. Azathioprine was added and bile duct loss (ductopenia) and pathological features and prognosis of PBC patients with premature ductopenic variant of primary biliary cholangitis

Tingting Lv1, Haitian Yu1, jidong Jia1, xinyan zhao1

1Liver Research Center, Beijing Friendship Hospital, Capital Medical University Beijing China

Objective: Some primary biliary cholangitis (PBC) patients present with prolonged cholestasis and extensive bile duct loss (ductopenia) but no significant fibrosis or cirrhosis. We aimed to clarify the clinical and pathological features and prognosis of PBC patients with premature ductopenia. Methods: This retrospective study recruited patients with early-stage PBC (Ludwig stage I or II). Demographic, laboratory, and pathological data were recorded, and clinical outcomes, including decompensated cirrhosis, liver transplantation or death, were followed up by interview. Logistic regression was conducted to identify the baseline features associated with ductopenia.

Results: A total of 141 patients with early-stage PBC were ultimately included, of which 34 had ductopenia and 107 did not have ductopenia. Early-stage PBC patients with ductopenia had higher levels of ALT, AST, ALP, GGT, TBIL, TBA, CHOL, and TG but lower levels of IgG and IgM at baseline than those without ductopenia (all P<0.05). Importantly, early-stage PBC with ductopenia had a lower response rate according to the Paris II, Barcelona and Rotterdam criteria. However, during a median follow-up period of 4.5 years, there was no significant difference in clinical outcome between early-stage PBC with vs. without ductopenia. Logistic regression analysis showed that baseline total CHOL levels were independent predictors for ductopenia. Conclusion: Ductopenia was a significant risk factor for worse biochemical profiles and poor treatment response but not for a short-term prognosis in early-stage PBC patients. High levels of CHOL at baseline may be associated with ductopenia in early-stage PBC patients.

Clinical characteristic and prognosis of premature ductopenic variant of primary biliary cholangitis

Analysis of diagnostic predictors in patients with PBC-AIH overlap syndrome from AIH

Li Zhang1, Hongmei Wu1, Li Liu2, Xiaofeng Shi2, Peng Hu1, Yu Lei3

1Institute for Viral hepatitis , Second Affiliated Hospital of Chongqing Medical University Chongqing China, 2Department of pathology, Second Affiliated Hospital of Chongqing Medical University Chongqing China

Background: Autoimmune hepatitis (AIH) is one of the main categories of autoimmune liver disease (AILDs). Approximately 10% of AIH patients displayed overlapping features of both AIH and PBC, referred as PBC-AIH overlap syndrome (PBC-AIH OS). This study aimed to explore the indicators for early diagnosis of PBC-AIH OS from AIH. Methods: By retrospective analysis, the general characteristics, clinical manifestations, biochemical tests, immunological tests, and liver histological examinations in patients with PBC-AIH OS and AIH at the time of initial diagnosis were analyzed. Univariate logistic regression analysis and multiple-factors analysis via multivariate logistical regression were used to predict the diagnosis of PBC-AIH OS based on the hematological indicators.

Results: A total of 105 AILDs patients were included in this retrospective study who underwent liver biopsy. There were no statistically significant differences in mean age, sex, or symptoms between PBC-AIH OS and AIH patients. Compared to AIH patients, PBC-AIH OS patients showed significantly high levels of serum globulin, ALP, GGT, PTA, AMA-M2, IgM and significantly low levels of ALT, AST and INR. The expression of ANA, ASMA, AMA and ROS2 were significant differences in these two groups. Univariate logistic regression analysis and multiple-factors analysis via multivariate logistical regression showed that GGT and AMA-M2 were significant predictors of PBC-AIH OS.

Conclusion: The degrees of cholestasis and dysimmunity in PBC-AIH OS patients were significantly higher than that in AIH patients. However, hepatocyte inflammation is more severe in patients with AIH. GGT and AMA-M2 can be used as noninvasive diagnostic indicators to predict PBC-AIH OS.

Clinical, serological and histological features of autoimmune liver diseases.

Kenwal Butani¹, Nazish Butt¹

¹Jinnah postgraduate medical center JPMC Karachi Karachi Pakistan

Autoimmune liver disease (ALD) is a rare spectrum of disease comprising of autoimmune hepatitis (AIH), primary biliary cirrhosis (PBC), primary sclerosing cholangitis (PSC) and overlap syndrome.

To evaluate the clinical, serological and histological features in patients presenting with autoimmune liver diseases in a tertiary care hospital in Karachi, Pakistan.

A cross-sectional case series of 31 patients which were enrolled in a study from January 2017 till date presenting at Jinnah Postgraduate Medical Center, Karachi. Demographic and clinical data including liver function tests, clotting profile, gamma globulin levels, autoimmune serology and liver histology were recorded on designed proforma.

Mean age of patients was 28.19±8.6 years. Females 23 (74.2%) and males 8 (25.8%). Most common symptom was fatigue (96.8%), followed by arthralgia (77.4%), anorexia and jaundice (61.3%). Type I AIH was present in 19 (61.3%), Type II AIH in 11 (35.5%) and AIH/PBC overlap in 1 (3.2%) patient respectively, however, no discrete case of PSC and PBC was reported. Immunoglobulin G level was raised in all patients with mean of 1672±530. Liver histology showed lymphoplasmacytic interface hepatitis in 19 (61.3%) patients and lobular hepatitis with centrilobular necrosis in 11 (35.5%) patients respectively.

Autoimmune liver disease can occur at any age, in both sexes with favorable results on immunosuppression. It can progress to several complications like decompensated liver disease, hepatocellular carcinoma, osteoporosis and dyslipidemia.

A worse subgroup of PBC: jaundice in patients with ductopenia

Tingting LV¹, Weijia Duan¹, Xinyan Zhao¹, Jidong Jia¹

¹Liver Research Center, Beijing Friendship Hospital, Capital Medical University Beijing China

Objective: Hyperbilirubinemia associated with poor prognosis of PBC, while not all PBC patients with ductopenia (bile duct loss greater than 50%) present prolonged jaundice. We aimed to clarify the clinicopathological features, prognosis and underlying mechanism of these subgroup icteric PBC patients with ductopenia.

Methods: This retrospective study recruited PBC patients with ductopenia diagnosed by liver biopsy. Demographic, clinicopathological data, treatment response and long-term prognosis of these patients were followed and recorded. Immunohistochemical stain of BSEP and MRP2 were conducted in these ductopenic patients with or without jaundice.

Results: A total of 265 patients with liver biopsy were included, of which 77 had ductopenia (18 accompanied with jaundice and 59 did not). We found ductopenic patients with jaundice had higher levels of TBIL, TBA, CHOL, and TG but a similar level of ALT, AST, ALP, GGT than those without jaundice (all P<0.05). Additionally, ductopenic PBC patients with jaundice had a lower survival rate when compared to those without jaundice (P<0.05). There was no significant difference in UDCA response between ductopenic PBC with or without jaundice (Paris II, Barcelona and Rotterdam criteria: P>0.05). The expression of BSEP and MRP2 was higher in patients without jaundice but significant lower in those with jaundice (P<0.05).

Conclusion: Jaundice does not seem to follow the same course as ductopenia in PBC. Ductopenic PBC patients with jaundice showed a similar worse treatment response but a poorer prognosis and uncompensated bile salt transporter helps to explain.

Late UDCA response is associated with worse prognosis of PBC patients compared to early response

Introduction: Our aim was to describe parameters after 6 months of UDCA treatment that are associated with poor prognosis in UDCA responders after 12 months of treatment.

Cohort of the patients: We analyzed 249 patients treated with UDCA for PBC at Slovak and Croatian centers; Patients were followed for a mean of 5.0 years. Therapeutic response after 12 months of treatment was defined according to Toronto criteria.

Results: 146 patients who achieved a response at 12 months using the modified Toronto criteria were included in the final analysis. 115 of these patients met the modified US criteria after 6 months of treatment - early responders; 31 patients did not meet these criteria after 6 months - late responders. Complete response was defined as normalization of total bilirubin and ALP at the last visit; optimal complete response was defined as bilirubin < 0.6 ULN and normalized ALP at the last visit. Early responders achieved complete response and optimal complete response at the last visit more frequently compared to late responders (59.1% vs. 38.7% p 0.043), (47.8% vs. 29% p 0.061). The risk of death and liver transplantation during the follow up was significantly lower in early responders compared to late responders (0% vs.4% p 0.041).

Conclusions: Late UDCA response is associated with increased mortality and less frequent complete therapeutic response to UDCA compared to early UDCA response. For PBC patients with inadequate UDCA response, second-line treatment should be considered after 6 months of treatment.

Building hepatic MRI models predict histopathological severity and insufficient response in AIH

Xiao Han, Dawei Yang, Yu Su, Qianyi Wang, Min Li, Jimin Liu, Jidong Jia, Hong Ma, Xinyan Zhao

1Liver Research Center, Beijing Friendship Hospital, Capital Medical University, Beijing, China. Beijing, China China, 2Department of Radiology, Beijing Friendship Hospital, Capital Medical University, Beijing, China Beijing China, 3Department of Clinical Epidemiology and EBM, National Clinical Research Center for Digestive Diseases, Beijing Friendship Hospital, Capital Medical University, Beijing, China. Beijing China, 4Department of Pathology and Molecular Medicine, Faculty of Health Sciences, McMaster University, Hamilton, Canada. Hamilton Canada

Abstract

Background: The correlation between hepatic magnetic resonance imaging (MRI) and liver histopathology has rarely been reported in autoimmune hepatitis (AIH). We built models using hepatic MRI features to predict histopathological severity/treatment response in AIH patients.

Methods: AIH patients with abdominal contrast MRI and liver biopsy were retrospectively retrieved from our AIH database (n=329, 2002-2023). Laboratory tests, hepatic MRI features and treatment response were collected. The liver volume was measured, and liver histopathological severity was evaluated according to the Ishak system. Models for predicting histopathological severity and response were constructed by logistic regression.

Results: Ninety-two AIH patients (median age: 56.50 years, 78.26% female) with simplified International AIH Group (IAIHG) scores ≥6 were included. Thirty-nine (42.39%) with severe confluent necrosis(≥5), 18 (19.57%) with advanced fibrosis(≥5). The MRI features of hepatic fissure widening, reticular fibrosis and the volume ratio of Couinaud segment II-IV vs. the total liver were independently associated with severe confluent necrosis; the enlarged preportal space, reticular fibrosis and the volume ratio of Couinaud segment I vs. the total liver were independently associated with advanced fibrosis; the ascites, gallbladder wall edema and transient hepatic attenuation difference were independently associated with insufficient response, with an area under the ROC curve of 0.827(95% CI 0.743-0.910), 0.911(95% CI 0.848-0.973) and 0.796(95% CI 0.691-0.902) respectively. The C-statistics of the internal validation were 0.818 (95% CI 0.683-0.929), 0.873(95%CI 0.730-0.973) and 0.757(95%CI 0.597-0.904) respectively.

Conclusion: The novel models including different MRI features for predicting histopathological severity and insufficient response were established in AIH.

Endoscopic Management of Primary Sclerosing Cholangitis: Clinical Outcomes at a Tertiary Center

Muhammad Bahaddin Durak, Bülent Odemis

1Lokman Hekim Akay Hastanesi Ankara Turkey, 2Bilkent City Hospital Ankara Türkiye

Background: Dominant strictures (DS) are a significant clinical feature in primary sclerosing cholangitis (PSC), and endoscopic treatment is crucial for managing DS and improving patient outcomes. This study aims to assess the clinical outcomes of endoscopic treatment for PSC-related DS.

Methods: A single-center, prospective study of consecutive PSC patients undergoing endoscopic treatment for DS management. The primary endpoint was the cumulative recurrence-free rate of the primary DS(s) within 24 months in patients who did not experience initial failure. Secondary endpoints were evaluated based on three parameters: 1) endoscopic treatment success, defined as no need for ERCP within three months after completing endoscopic treatment; 2) development of cirrhosis; and 3) recurrence of DS.

Results: A total of 35 patients were included. In total, 138 endoscopic treatment sessions were performed, with an average of 3.9 sessions per patient. DS was identified in 26 patients during cholangiograms. Endoscopic balloon dilation (EBD) was applied in 24 (68.6%) patients, while nine patients (25.8%) underwent bougie dilation. The average stent duration for the initial procedure was 17.9 days. 26 (78.8%) patients remained asymptomatic within three months of discharge and remained cirrhosis-free during a mean follow-up period of 36 months. This was the secondary endpoint of the study. The primary end-point
achievement rate was 45.4%. The complication rate was 8.0%, including pancreatitis, cholangitis, and perforation. The cholangiocarcinoma (CCA) development rate was 5.7%.

**Conclusion:** Endoscopic treatment, including stent placement and biliary dilation, effectively manages PSC-related DS, with high success and relatively low complication rates.

**Scoring system is prognostic model of primary biliary cholangitis treated with UDCA and fenofibrate**

**Shuxiang Li1, Buer Li1, Weijia Duan1, Yu Wang1, Xinyan Zhao1, Hong You1, Jidong Jia1**

1Liver Research Center, Beijing Friendship Hospital, Capital Medical University beijing, china china

**Background:** Fenofibrate as the second-line therapy for ursodeoxycholic acid (UDCA)-refractory primary biliary cholangitis (PBC) patients is becoming widely used, but no model can test the efficacy of the second-line therapy. Thus, this study aimed to investigate the biochemical response model that can predict the efficacy and long-term prognosis for patients treated with fenofibrate add-on therapy.

**Methods:** We enrolled UDCA-refractory PBC patients treated with fenofibrate and UDCA. These patients were grouped into the good outcome group and the poor outcome group according to a combined endpoint (hepatic decompensation, liver-related death, and liver transplantation). Patients are followed up by medical records, outpatient service, and telephone reviews. The biochemical response (Barcelona, Paris-I, Paris-II, Toronto, Rotterdam, Mayo, Ehime, Lindor, GLOBE score, and UK-PBC risk score) compared after 6 or 12 months of fenofibrate added-on therapy, and to identify a biochemical response model that can predict long-term prognosis by Kaplan-Meier plotting and Delong test.

**Results:** Sixty-three patients were enrolled in this study, including the good outcome patients (n=52) and the poor outcome patients (n=11). The poor outcome patients had higher GLOBE scores and UK-PBC risk scores than the good outcome patients after 12 months of treatment (GLOBE score: 1.1925±1.1061 vs. -0.2363±0.6666 (p<0.01), UK-PBC risk score: 0.1395 (0.0702, 0.2285) vs. 0.0311 (0.0210, 0.0511) (p<0.0001)). And other biochemical response criteria including Barcelona, Paris-I, Paris-II, Toronto, Rotterdam, Mayo, and Ehime didn’t show statistically significant differences between these two groups. More importantly, the GLOBE score and UK-PBC risk score had better predictive performance of long-term survival in patients with fenofibrate add-on therapy than these criteria. The area under the receiver operating characteristic (AUROC) of GLOBE score and UK-PBC risk score at 6 months of 0.871 (95%CI 0.741-0.951) and 0.875 (95%CI 0.746-0.953), and 12 months of 0.919 (95%CI 0.803-0.978) and 0.878 (95%CI 0.751-0.955). All other criteria were lower than 0.750 for the prediction of long-term survival after 6 or 12 months of treatment with UDCA and fenofibrate.

**Conclusions:** The GLOBE score and UK-PBC risk score were suitable for predicting the efficacy and long-term prognosis for PBC patients with fenofibrate and UDCA treatment.

**Genetic link between Periodontitis and liver diseases: a Mendelian randomization study**

**Yunling Xue1, Xiaoxiao Liu1, Qiao Tang1, Yi Zeng1, Mingli Peng1, Peng Hu1**

1ChongQing Medical University Chongqing China

**Background & aims:** The relationship between periodontitis and liver disease has received increasing attention in recent years, but the causal relationship is unclear. The aim of this study was to assess the causal relationship between periodontitis and various liver diseases

**Method:** We performed two-sample Mendelian randomization (MR) analysis. Suitable genome-wide association study (GWAS) datasets were used to select potential candidate single nucleotide polymorphisms according to the study needs. Inverse variance weighting (IVW) was used as the primary analysis method, supplemented by four sensitive analyses to assess the robustness of the results.

**Results:** Among the included liver diseases, only the genetic variant of PSC was causally associated with the risk of chronic periodontitis. According to IVW estimates, the presence of PSC may increase the risk of chronic periodontitis by 1.079% (OR 1.079, 95% CI 1.027-1.134, p = 0.002, MR-Egger, Weighted mode and Weighted median also produced similar results. Conversely, periodontitis did not have an impact on the risk of developing the liver diseases included in this study.

**Conclusion:** We investigated for the first time the association between several liver diseases and periodontitis using a Mendelian randomized study method and found that PSC increases the risk of chronic periodontitis.

**Pyroptosis plays a key role in primary biliary cholangitis in mice**

**Linxiang Huang1, Zilong Wang1, Jiarui Zheng1, Zixuan Qiu1, Bo Feng1**

1Peking University People’s Hospital Beijing China

**Background and Aims:** Primary biliary cholangitis (PBC) is an autoimmune intrahepatic cholestatic disease with both environmental and genetical participation. In this study, we aim to investigate the involvement of pyroptosis in PBC mice and provide possible treatment strategy.

**Method:** Twenty female C57BL/6 mice of 4-6 months old were evenly divided into PBC group and control group. PBC mice were induced with two doses of 2-nonynoic acid (2OA-BSA) and polycytidylic acid (poly I: C) for 12 weeks. Immunocyte type correlation analysis was performed on the GSE119600 dataset of GEO database with whole blood samples from PBC patients (n=90) and controls (n=47). Immunohistochemistry (IHC) staining and multiplex immunofluorescence (mIF) in liver samples of PBC mice were determined regarding the pyroptosis pathway and different cell types.

**Results:** Immunocyte type correlation analysis reported that the expression of key transcription factors of M1 macrophages were significantly higher in PBC patients (Figure A). For PBC mouse model, pyroptosis pathway was upregulated determined by qrt-PCR (Figure B) and western blotting (Figure C). IHC staining revealed improved GSDMD and Caspase-1 expression in PBC mice (Figure D), and macrophages were determined to be the main cell type expressing GSDMD by mIF (Figure E). Flow cytometry showed an increased M1/M2 macrophage ratio in liver samples of PBC mice, with the expression of M2 macrophage marker decreasing and the marker of M1 macrophage increasing in the western blotting.

**Conclusion:** Pyroptosis plays a key role in PBC patients and 2OA-BSA induced PBC mice, possibly macrophages being the most important executors.

Urinary Tract Infection and Pyuria in Primary Biliary Cholangitis

Dilara Turan Gökçe1, Hasan Erzurun2, Amed Trak1, İlayda Ergene3, Zekiye Nur Harput4, Neslihan Güneş Aydemir2, Derya Arslan2, Hasan Basri Yapıcı2, Haydar Adanır2, Orhan Sezgin2, Yusuf Vural1, Ahmet Bektaş2, Meral Akdoğan Kayhan1

1Ankara Bilkent City Hospital, Department of Gastroenterology, Ankara Turkey, 2Ondokuz Mayıs University, Department of Gastroenterology Samsun Türkiye, 3Marmara University, Department of Gastroenterology İstanbul Türkiye, 4Süleyman Demirel University, Department of Gastroenterology Antalya Türkiye

Introduction: Primary biliary cholangitis (PBC) is a chronic cholestatic autoimmune liver disease primarily affecting women and urinary tract infection (UTI) have a role in pathogenesis.

Method: The study aimed to assess demographic characteristics, treatment responses, and the presence of asymptomatic pyuria or urinary tract infection in PBC patients across five different centers. Patients receiving 13-15 mg/kg UDCA treatment for at least one year and consenting to participate were included. Patients with symptomatic pyuria, currently using antibiotics, or having symptomatic UTIs were excluded.

Results: Among the 229 participants, 90.5% (Female: 207) were female, with a mean age of 59.4 (11.2) years. Treatment unresponsiveness was observed in 13.5% (n=31) of the patients. Regarding symptomatic UTIs, 25.4% (n=55) experienced at least one UTI before PBC diagnosis, and 16.9% (n=38) had two or more UTIs. Additionally, 17.5% (n=40) had a history of UTIs more than once a year. No significant association was found between UTI history and treatment response (p: 0.64 and 0.93, respectively). Among the 229 patients, 105 (45.8%) had asymptomatic pyuria, and in 16 (7.4%), urine cultures showed bacterial growth, with Escherichia Coli being the predominant pathogen in 8 cases, followed by Klebsiella pneumoniae and Streptococcus Agalactica. Analyses revealed that the frequency of asymptomatic pyuria was not higher in treatment-unresponsive patients but was more common in cirrhotic patients (p: 0.028).

Conclusion: In our study, no correlation was found between symptomatic UTIs and treatment unresponsiveness. Similarly, asymptomatic pyuria and positive urine cultures did not increase in unresponsive patients.

Genetic risks of “one-pill” NSAIDs induced liver injury: a real-world study

Yangjie Li1, Lingna Lyu1, Hui guo Ding1

1Department of Gastroenterology and Hepatology, Tongji Hospital, Shanghai University of Traditional Chinese Medicine, Shanghai, China

Background: Genetic risks of “one-pill” NSAIDs-DILI is associated with polymorphic expression of several genes. Our study not only verified reported gene variants but also revealed new SNPs contributing to NSAIDs-related DILI.

Conclusion: “One pill” NSAIDs-DILI is associated with polymorphic expression of several genes. Our study not only verified reported gene variants but also revealed new SNPs contributing to NSAIDs-related DILI.

Hepatic MUM1 expressions distinguish drug-induced liver injury from acute-onset autoimmune hepatitis

Zikun Ma1, Mengmeng Zhang1, Yao Meng1, Yu Wang1, Tian Tian Guo1, Yan Wang1, Min Li1, Xinyan Zhao1, Jimin Liu1
1Liver Research Center, Beijing Friendship Hospital, Capital Medical University, Beijing, China, Beijing China, 2Department of Clinical Epidemiology and EBM, National Clinical Research Center for Digestive Diseases, Beijing Friendship Hospital, Capital Medical University, Beijing, China Beijing China, 3Department of Pathology and Molecular Medicine, Faculty of Health Sciences, McMaster University, Hamilton, Ontario, Canada Ontario Canada

Background: Perivenular necroinflammation is a common but easily confused histological characteristic in both drug-induced liver injury (DILI) and acute-onset autoimmune hepatitis (A-AIH). We aimed to evaluate multiple myeloma antigen 1 (MUM1) immunohistochemistry (IHC) stain in distinguishing DILI from A-AIH.

Method: DILI or A-AIH patients with liver biopsy matched by propensity score were retrieved from DILI (n=138) and AIH (n=125) database from 2016 to 2023. Liver biopsies were evaluated according to the modified histological activity index (mHAI), MUM1-expression cells were quantified by ImageJ. The diagnostic performance of MUM1 IHC stain was assessed by an area under the receiver operating characteristic curve (AUROC).

Results: Eligible DILI (n=10) and A-AIH (n=10) patients: the median age was 52 (38.3, 57.8) years, and females were 16 (80.0%). There was no significant difference of age, gender, aminotransferase, bilirubin and immunoglobulin G levels at onset and mHAI scores between two groups. In portal areas, both total and average number of MUM1-expression cells per square millimeter were significantly higher in A-AIH than that in DILI: 561.5 (226.8, 839.5) versus 226.0 (144.8, 445.5); 621.3(336.1,809.1) versus 260.2(163.2,428.6), respectively (all P<0.05). Total or average number of MUM1-expression cells or their combination in portal areas yielded an AUROC of 0.79 (95% CI: 0.5844-0.9956), 0.86 (95% CI: 0.6977-1.0000) or 0.85 (95% CI: 0.6784-1.0000) respectively in distinguishing DILI versus A-AIH. A cutoff value of 472.8 for average MUM1-expression cells per square millimeter in portal areas had a specificity of 90.0% and a sensitivity of 70.0%.

Conclusion: The number of MUM1-expression cells in liver biopsy specimens can effectively distinguish DILI from A-AIH.

Abstract Submission No. 101864

Clinical features of acute drug-induced liver injury with pathological severe hepatic inflammation

George Lau1, Yu-ting Xiong1, 2, Chun-yang Wang1, Jie Chen4, Dong Ji8
1Humanity and Health Medical Group Hong Kong Hong Kong, 2307 Clinical Medical College of PLA, Anhui Medical University Beijing China, 3Senior Department of Hepatology, Fifth Medical Center of Chinese PLA General Hospital Beijing China, 4JC School of Public Health and Primary Care, Faculty of Medicine Hong Kong SAR China

Background: Research on biopsy-proven acute drug-induced liver injury (DILI) remains limited. This study aimed to identify clinical characteristics of acute DILI with pathological severe hepatic inflammation.

Methods: A prospective hospitalization-based cohort study was conducted on biopsy-proven acute DILI patients admitted to our hospital from 2009 to 2017, and followed up until October 2023. The clinical characteristics at the time of liver biopsy, discharge, and follow-up were collected. According to Scheuer scoring system, hepatic inflammation was categorized as mild (G0-2) and moderate/severe (G3-4) groups, and between-group comparisons and multivariate logistic regression analyses were performed.

Results: The median age of 157 enrolled patients was 40.4 years, with 65.6% female. The median length of stay was 18 (IQR, 12.0-26.0) days. Liver injury induced by traditional Chinese medicine, chemical synthetic drugs and mixed drugs accounted for 42.7%, 25.5% and 31.8%, and the median incubation period was 14.0 (IQR, 7.0-30.0) days. Logistic regression analysis revealed that female (OR: 2.420, 95% CI: 1.311,1.311, P=0.024) were independent risk factors for moderate-to-severe hepatic inflammation, while increasing HCL. C (OR: 0.360, 95% CI: 0.131-0.992, P=0.048) was protective. During follow-up, 23 patients (14.6%) developed chronic DILI, with 9 patients (5.7%) progressing to cirrhosis, and 15 patients combined with autoimmune (G0-2 group 3 vs G3-4 group 12, P<0.05).

Conclusions: Being female and having high BMI are associated with a higher risk of developing severe hepatic inflammation, which can lead to chronicity when compounded with autoimmune factors.

Close relationship between hepatotoxicity and adverse events of other organ induced by ICPI therapy
Yu Akazawa1, Takuto Nosaka1, Tomoko Tanaka1, Kazuto Takahashi1, Tatsushi Naito1, Hiteda Matsuda1, Masahiro Ohtani1, Yasunari Nakamoto1
1Second Department of Internal Medicine, Faculty of Medical Sciences, University of Fukui Fukui Japan

Background: With the widespread use of immune checkpoint inhibitors (ICIs), the diagnosis and treatment of immune-related adverse events (irAEs) has become increasingly important. Although, immunemediated hepatotoxicity (IMH) is a relatively common, clinical evaluation of IMH remains unclear. The aim of this study was to clarify the clinical characteristics in patients with IMH.

Methods: The patients with advanced cancer who received ICPI from September 2014 to December 2022 in our department were enrolled for this retrospective study. In enrolled patients, the incidence and severity of IMH were evaluated. Additionally, clinical factors that related to the onset of IMH were analyzed by multivariable logistic regression analyses. The onset and severity of IMH and other organ irAEs were defined according to CTCAEv5.0.

Results: A total of 617 patients (468 males, 149 females; median age, 70.0 years) were enrolled in this study. Of all, 61 patients (9.9%) developed hyperamylasemia: Grade 2 (G2), Grade 3 (G3), and Grade 4 in 34, 27, and 0 patients. In univariate analysis, ICPI combination therapy (p=0.038), and the onset of other organ irAE (≥G2) (p<0.001) were significantly related to development of IMH. In multivariate analysis, only the onset of other organ irAE (≥G2) (p<0.001) was the independent factor associated for the onset of IMH. Also, the incidence of other organ irAE ≥ G3 was higher in the case with G3 IMH than in the case with G2 IMH, resulting in a correlation between the severity of IMH and other organ irAE (p=0.02).

Conclusions: The onset and severity of IMH was closely related to these of other organ irAEs in patients with ICPI therapy. This finding suggests that in cases with IMH, more intensive systemic management is required because of the potential for multiple organ irAEs.

FIVE-YEAR SINGLE-CENTER EXPERIENCE IN ACUTE HEPATOTOXICITY DUE TO HERBAL MEDICATIONS FROM PAKISTAN
Farhana Kayani1, Jalal Khan2
1Bolan medical college, Quetta Pakistan, 2Sheikh Khalifa bin zayed hospital quetta pakistan

Background & aims: Injury to liver secondary to herbal medication is quite common. It can cause acute liver injury and acute liver failure (ALF) requiring Liver transplantation. We investigated outcomes of patients with acute Hepatotoxicity due to herbal medications in our cohort.

Method: We prospectively evaluated characteristics of patients with liver toxicity due to herbal medications. We also investigated parameters related to mortality or liver transplantation.

Results: 30 patients (17/13: f:m, median age 50.4(22-73)) were included in study. 27 patients presented with nausea and vomiting. In addition, 14 patients had abdominal pain & 16 had diarrhea. These patients were admitted to our intensive care unit within an average of 2.5 days (6 hours-8 days) after herbal medication intake. In 15 patients (14 at admission, 0 during hospitalization), INR increased > 1.5. ALF developed in 4 patients (02 patients at admission, hepatic encephalopathy developed in two patients during follow up). The peak levels of ALT, AST & total bilirubin were 2109±1963 μl/l, 1828±1675 μl/l, 4.92 (0.1-28.56 mg/dl), respectively. In hospital follow up, highest INR levels were found to be an average of 2.29 (±1.56). All patients were treated with N-acetylcysteine (NAC). One of the 04 patients with ALF underwent emergency liver transplantation. 01 patient who developed ALF recovered with medical treatment, while other 02 patients who could not be transplanted died. In multivariate analysis, INR, AST & ALT levels at hospital admission were found to be statistically significant factors for death & liver transplantation respectively; or: 17.8 and p: 0.04. or:0.59 & p:0.03 &or: 0.54 & p: 0.04.

Conclusion: In our cohort, the mortality rate due to herbal medication intoxication was 10%. High INR levels, ALT & AST levels have been associated with serious outcomes such as liver transplantation or mortality, these parameters may be predictive of urgent liver transplantation.

Abstract Submission No. 100569

N-acetylcysteine can accelerate the recovery of drug-induced cholestatic liver injury
En-Qiang Chen1, Cheng-Run Song1, Yu-Jing Li1, Lan-Qing Li1, Rong Deng1, Xue-Zhong Lei1, Li-Chun Wang1, Tao-You Zhou1, Fang He1, Ping Feng1, Hong Tang1
1West China Hospital, Sichuan university Chengdu China

Objective: To observe the effectiveness of N-acetylcysteine in the treatment of drug-induced cholestatic liver injury.

Method: A retrospective study was conducted on hospitalized patients with drug-induced cholestatic liver injury from West China Hospital between January 2019 to June 2023. On the basis of adenosylmethionine and ursodeoxycholic acid treatment, the effectiveness of adding or not adding N-acetylcysteine were investigated.

Result: A total of 265 patients were included, including 84 males and 181 females, with an average age of 51.3 years. In terms of etiology, there were 98 cases caused by acetaminophen, 102 cases of traditional Chinese medicine or dietary supplements, 53 cases caused by other chemical drugs, and 12 cases of other causes. Among 265 patients, 137 received N-acetylcysteine treatment (Group A), while 128 patients did not receive N-acetylcysteine treatment (Group B). The levels of TBil (314.6±45.8 μmol/L vs. 307.5±43.5 μmol/L, P=0.198) were similar between the two groups at admission, but the levels of ALP (462.9±48.6 IU/ml vs. 448.5±50.2 IU/ml, P=0.018) and GGT (436.5±52.7 IU/ml vs 423.7±40.1 IU/ml, P=0.044) in Group A were higher than those in Group B. Among group A, 42 patients were hospitalized for less than 2 weeks, while 95 patients were hospitalized for more than 2 weeks. Among group B patients, 26 patients were hospitalized for less than 2 weeks, while 102 patients were hospitalized for more than 2 weeks. The average hospitalization time of Group A patients was significantly shorter than that of Group B patients (9.3±3.1 vs.11.1±2.2 day, P=0.05), and the 2-week discharge rate was significantly higher than that of Group B (42/137 vs.26/128, P<0.05). At 2 weeks of hospitalization, the serum TBil of Group A were significantly lower than that of Group B (128±24.9 vs. 142.7±31.5 IU/ml, P<0.001), and the levels of ALP (103.5±26.4 vs. 145.7±30.3 IU/ml, P<0.001) and GGT (111.2±24.8 vs 128.9±26.4 IU/ml, P<0.001) were also significantly lower than those of Group B.
Conclusion: On the basis of combined treatment with adenosylmethionine and UDCA, the addition of N-acetylcysteine can accelerate the recovery of damaged liver function.

Abstract Submission No. 100739

Usefulness of RECUM as a diagnostic criterion for drug-induced liver injury in Japanese patients

Yasuyuki Komiyama1, Reona Osawa1, Hitomi Takada1, Masaru Muraoka1, Yuichiro Suzuki1, Mitsuaki Sato1, Shinya Maekawa1, Nobuyuki Enomoto1

1Department of Gastroenterology and Hepatology Chuo Yamanashi Japan

Background: In Japan, DDW-J2004 based on RUCAM is used as a diagnostic tool for drug-induced liver injury (DILI). Recently, RECUM was reported as a new diagnostic tool, but it has not been fully investigated in Asian countries, including Japan, and we aimed to investigate the usefulness and problems of RECUM in Japan.

Methods: We included 120 cases with a diagnosis of DILI or suspected DILI between January 2020 and October 2022, and added RECUM scoring retrospectively to evaluate the rate of concordance of diagnosis. We also examined the characteristics of cases in which there was a dissociation of diagnosis.

Results: There was a strong correlation between RECUM and DDW-J scores (R=0.586, p<0.001). All patients with a highly likely DILI on the RECUM were also categorized as likely on the DDW-J. On the other hand, among the cases diagnosed as highly likely by DDW-J, there were 5/37 cases (13.5%) diagnosed as excluded by RECUM. DILI was considered negative in both cases: 2 cases because of time of onset and 3 cases because of other diagnoses (HEV, AIH, other). In addition, there were 19/54 cases (35.2%) who were diagnosed as exclusionary by RECUM among those who had been diagnosed with undeniable possibility of DILI by DDW-J. When examining the reasons for the lower scores, data loss was predominant in the excluded diagnosis items (number of missing data items 3(0-4) vs. 4(2-6), p<0.001).

Conclusions: The results suggest that RECUM may be useful in Japanese patients; however, caution should be exercised in cases of high data loss, as RECUM has a point reduction due to missing data. It should be used with a thorough understanding of how to exclude competing diagnoses.

Efficacy of magnesium isoglycyrrhizinate in liver injury after receiving novel antineoplastic agents

Yang Zhi1,2, Yimin Mao1,2, Xiaoyun Li1,2, Yinuo Dong1,2

1Department of Gastroenterology and Hepatology, Shanghai Institute of Digestive Disease, Renji Hospital, School of Medicine, Shanghai Jiao Tong University Shanghai China, 2Clinical Research Center, Shanghai Jiao Tong University School of Medicine Shanghai China

Background: Liver injury often occurs in patients treated with novel antineoplastic agents including molecular targeted agents and immune checkpoint inhibitors. Magnesium isoglycyrrhizinate (MgIG) is an anti-inflammatory agent with potential to ameliorate liver injury.

Methods: We conducted a retrospective, multicenter, real-world study to evaluate the efficacy of MgIG compared to glucocorticoids in patients with liver injury after receiving any novel antineoplastic agent. Propensity score matching (PSM) is used to match age, sex, and baseline alanine aminotransferase (ALT) between groups. The change from baseline, normalization rate and the proportion of patients with 50% reduction of ALT, aspartate aminotransferase (AST) and total bilirubin (TBIL) 7 days after treatment and before discharge were compared.

Results: A total of 979 cases are included and subsequently divided into 2 populations after PSM in a 1:1 and 3:1 ratio respectively: MgIG (n=152) vs. supportive care (SC) (n=152); and MgIG + SC (n=497) vs. SC (n=171). The normalization rates and 50% reduction rates of ALT, AST, and TBIL is significantly higher in MgIG group than those in SC group (n=152) before discharge, while only 50% reduction rates reached statistical significance at day 7. In MgIG + SC group, normalization rates of only ALT and AST is significantly higher than those in SC group (n=171) before discharge, while 50% reduction rates of all compared serum markers reached statistical significance both at day 7 and before discharge.

Conclusion: This study provided preliminary evidence for the efficacy of MgIG in patients with liver injury after receiving novel antineoplastic agents compared to supportive care.

Abstract Submission No. 100910

Efficacy of MgIG compared to steroids in liver injury after novel antineoplastic therapy

Yinuo Dong1,2, Yimin Mao1,2, Yang Zhi1,2, Xiaoyun Li1,2

1Department of Gastroenterology and Hepatology, Shanghai Institute of Digestive Disease, Renji Hospital, School of Medicine, Shanghai Jiao Tong University Shanghai China, 2Clinical Research Center, Shanghai Jiao Tong University School of Medicine Shanghai China

Background: Liver injury in patients treated with novel antineoplastic agents including molecular targeted agents and immune checkpoint inhibitors is often managed with glucocorticoids. Magnesium isoglycyrrhizinate (MgIG) is an anti-inflammatory agent with potential to ameliorate liver injury.

Methods: We conducted a retrospective, multicenter, real-world study to evaluate the efficacy of MgIG compared to glucocorticoids in patients with liver injury after receiving any novel antineoplastic agent. Propensity score matching (PSM) is used to match age, sex, and baseline alanine aminotransferase (ALT) between groups. The change from baseline, normalization rate and the proportion of patients with 50% reduction of ALT, aspartate aminotransferase (AST) and total bilirubin (TBIL) 7 days after treatment and before discharge were compared.

Results: A total of 918 cases are included and subsequently divided into 2 populations after PSM in a 1:1 and 2:1 ratio respectively: MgIG (n=57) vs. supportive care (SC) (n=249); and MgIG + glucocorticoids + supportive care (SC) (n=249) vs. glucocorticoids + SC (n=164). MgIG group only showed a higher 50% reduction rate in TBIL over glucocorticoids group at day 7 and before discharge. However, the normalization rate of ALT and AST before discharge in MgIG + glucocorticoids + SC group are significantly higher than those in glucocorticoids + SC group. The 50% reduction rates of all compared serum markers reached significantly higher at day 7 and before discharge.

Conclusion: This study provided evidence that MgIG may aid to improve recovery as add-on therapy to glucocorticoids and supportive care in patients with liver injury after receiving novel antineoplastic agents.

O-0056
Late Onset Efavirenz Induced Liver Toxicity in a 17-year-old, Filipino, HIV patient

John Derek Clutario1, Gerardo S Pedregosa1, Janice C. Caoli1
1Makati Medical Center Pasig City Philippines

Efavirenz, a commonly used non-nucleoside reverse transcriptase inhibitor (NNRTI) for HIV treatment, is generally well-tolerated. However, rare cases of hepatic adverse effects, including hepatotoxicity, have been reported. While mild liver enzyme elevations are relatively common (in about 10% to 20% of cases), severe hepatotoxicity leading to liver failure is infrequent, with reported incidences ranging from 0.5% to 4%. The exact mechanisms underlying efavirenz-induced liver toxicity are not fully understood but may involve oxidative stress, mitochondrial dysfunction, and immune-mediated reactions.

In this case report, a first in the Philippines, we present a known case of HIV started on Lamivudine, Tenofovir and Efavirenz who presented with jaundice and elevated liver enzymes after a year of treatment which has not happened before in any published case. A comprehensive workup ruled out various causes of acute liver injury, including infection, autoimmune factors, herbal medications, and toxins. Genetic testing did not reveal any abnormalities related to medication metabolism. The patient’s condition was successfully managed with a combination of steroids, immunosuppressants, and switching from efavirenz to dolutegravir, leading to the resolution of jaundice and liver enzyme abnormalities.

This case highlights a delayed onset of efavirenz-induced liver toxicity, occurring after a year of HIV treatment initiation. It emphasizes the importance of early detection, comprehensive workup, and personalized management for rare adverse effects associated with antiretroviral therapy. Understanding efavirenz-induced liver toxicity, including its mechanisms, risk factors, and clinical management, is crucial for the safe and effective treatment of HIV patients.

O-0057

CTCAE system upgrades severity of ICIs induced liver injury than DILI grading systems

Yan Wang1, Liwei Liu2, Mengyu Zhao1, Wei Chen1, Xinyan Zhao1
1Beijing Friendship Hospital, Capital Medical University Beijing China, 2Beijing Youan Hospital, Capital Medical University Beijing China

Background: Immune-mediated liver injury (ICILI) induced by immune checkpoint inhibitors (ICIs) are usually graded by the Common Terminology Criteria for Adverse Events (CTCAE) grading system. While the grading systems for drug-induced liver injury (DILI) include the US Drug-induced Liver Injury Network (DILIN) and the International DILI Expert Working Group severity indexes. It remains unclear which of these systems is most appropriate for assessing the severity of ICILI.

Method: This is a retrospective review at Beijing Friendship Hospital (2016-2022) collecting clinical data of ICI-treated patients. ICILI cases were graded using CTCAE and two other DILI indexes. Agreement and correlation between grading systems were analyzed using the weighted kappa coefficient and Spearman’s rho coefficient.

Results: A total of 66 (4.94%) cases developed ICILI. In summary, 18 (27.3%) cases exhibited ALT elevation, 23 (34.8%) AST elevation, 9 (13.6%) ALP elevation, and 16 (24.2%) TB elevation exceeding grade 3 in terms of liver injury severity with CTCAE systems. CTCAE identified a higher proportion of severe cases compared to US-DILIN and International systems significantly 45.5% vs 16.7% and 16.7%, respectively, P=0.001. Correlation analysis showed higher agreement between US-DILIN and International (κ=0.642, 95%CI 0.517-0.766) than with CTCAE (κ=0.188, 95%CI 0.091-0.285 with International; κ=0.239, 95% CI 0.108-0.371 with US-DILIN).

Conclusions: CTCAE graded more ICILI cases as severe cases compared to DILI grading systems. A comprehensive assessment incorporating clinical presentation, liver chemistries, coagulation function, and prognosis is crucial for accurate severity determination.

Abstract Submission No. 101402

Clinicopathological features and outcomes of Scutellaria (Huang Qin)-induced liver injury

Tiantian Guo1, Yao Meng1, Yu Wang1, Zikun Ma1, Mengmeng Zhang1, Yan Wang1, Min Li1, Jimin Liu2, Xinyan Zhao1
1Beijing Friendship Hospital, Capital Medical University Beijing China, 2Faculty of Health Sciences, McMaster University, Hamilton, Canada Hamilton Canada

Objective To investigate clinicopathological features and outcomes of liver injury induced by Scutellaria, a herb known as Huang Qin.

Methods This is a multi-center retrospective cohort study. Cases with Scutellaria-induced liver injury were collected from Beijing Friendship Hospital, Beijing You’an Hospital, and the Fifth Medical Center of PLA General Hospital, from January 2009 to June 2017. Clinicopathological data and follow-up final clinical outcomes were summarized.

Results Twenty-nine patients with Scutellaria induced liver injury were identified from 1444 herb-induced liver injury cases. The median age was 48 (37, 59) years and 75.9% (24/29) were women. The most common symptom was dark-color urine (79.3%, 23/29). The main clinical injury pattern was hepatocellular (72.4%, 21/29), followed by mixed (17.2%, 5/29) and cholestatic (10.3%, 3/29). Of nine patients with liver biopsies, six had acute hepatitic and three had mixed acute cholestatic-hepatitic histological injury pattern. Compared to the mild group (n=12), moderate and severe group (n=13), the acute liver failure (ALF) and fatal group (n=4) had significantly higher level of aspartate aminotransferase (515.5 and 655.04 vs 1064.5 U/L) and prolonged prothrombin time (11.5 and 12.0 vs 16.3 s), lower level of albumin (39.5 and 38.6 vs 33.8 g/L, all P<0.05). One patient in the moderate and severe group had chronic liver injury, whereas, one developed chronicity and one died of liver failure in the ALF and fatal group.

Conclusion Scutellaria can induce liver injury, and the main clinicopathological injury pattern was acute hepatitis with or without cholestasis. Most patients recovered; however, chronicity and death may occur.

Non-alcoholic fatty liver disease following chemotherapy

Amar Ranjan1, Harshita Dubey1, Pranay Tanwar1
1AIIMS, Delhi New Delhi India

Introduction: Chemotherapy-induced liver injury is one of the most common causes of mortality in cancer patients. One of the mechanisms of the development of fatty liver is hepatic steatosis, induced by chemotherapeutic agents. In this study, we are evaluating the development of fatty livers during the therapy for ovarian cancer.
Method: A prospective study was conducted on cases of ovarian cancer with normal liver function tests who developed fatty livers after getting chemotherapy.

Result: We studied 200 cases of ovarian cancer, out of which 31 (15%) cases developed fatty liver secondary to therapy for ovarian cancer. The average age at which fatty liver develops is 49.2 years. Among various clinical parameters, only weight and body surface area (BSA) did show a statistically significant correlation (p = 0.05) with the development of fatty liver. The patients who had PFI for more than 15 months also showed the development of FL (P = 0.03) (table 1).

Conclusion: The development of fatty liver following chemotherapy follows the common mechanism, but the process is fast. This may be due to an altered metabolic process. Here also weight and BSA are associated with the development of fatty liver. Following chemotherapy, progression-free interval has also shown a significant correlation with the development of fatty liver.

Analysis of International Comparisons of Adverse Drug Reaction Reports in FDA and PMDA Databases

Hiroteru Kamimura1, Takafumi Tonouchi1, Suguru Miida1, Atsunori Tsuchiya1, Shuji Terai1

1Niigata University Niigata Japan

Background: An international comparison was made in the liver-related drug adverse event databases of FAERS (Food and Drug Administration Adverse Event Reporting System) by the FDA in the USA and JADER (Japanese Adverse Drug Event Report) by the PMDA in Japan.

Methods: An international comparison in the databases of liver-related adverse drug events was conducted. Standardised medical terminology with high quality and specificity internationally. Both databases available with seven types of Preferred terms reported as liver-related adverse events registered in MedDRA internationally.

Results: Warfarin was the drugs most associated with adverse liver events in 452,272 cases registered in FAERS from 1997 to 2019. Sorafenib in 38,919 cases registered in JADER from 2004 to 2019, nivolumab and herbal extracts were the drugs most associated with adverse hepatic events. There was no correlation between the rankings in both databases. In terms of post-report outcomes, FAERS accounted for 43% of severe cases, while JADER accounted for 83% of severe cases. Pattern of liver injury was hepatocellular in 25.1%, cholestatic in 56.17%, mixed in 18.72% of patients. The patients with prior drug allergy were mainly male (78%) & significantly older, with mean age of 54 vs 45 with no prior drug allergy (P = .009), & they were more likely to have an underlying chronic disease like diabetes & Hypertension (P = .016). Clinically, patients with prior drug allergy were more encephalopathic (21.6% vs 10; P = 0.02) & jaundiced (54.1% vs 38%; P = 0.04). Those with prior drug allergy also had significantly hepatocellular pattern of DILI (68% vs 35%; P = 0.003), lower median values of albumin (2.8g/L vs 3.8g/L; P = 0.04) & a combination of ALT & AST were significantly higher in patients with prior drug allergy (9.4 vs 6.2; ULN; P = 0.04), (8.5 vs 4.2 mg/dl; P = 0.02) & (5 vs 3.5; P = 0.01). Among those with prior drug allergies, leading drugs most commonly responsible for injury were Anti-tuberculosis drugs (ATDs) (20%), followed by herbal medicines. In-hospital mortality was more in patients with prior drug allergy as compared to other arm (26.5% vs 10; P = 0.034) & prolonged hospital stay (>7 days) was observed to be more in drug allergy arm but not statistically significant (35.93% vs 28.6; P = 0.43).

Conclusion: Patients presenting with history of prior drug allergies, one have to be careful while prescribing medications & if any present with DILI, they require close monitoring for early detection of worsening clinical courses.

N-Acetylcysteine Prophylaxis for Anti-Tuberculosis Drug Induced Hepatotoxicity: A Meta-Analysis

Maxine Andrea T Garcia1, Ma. Felina Rosanna G Siray1, Laurence E Laurel1, Ma. Regina D Dimaculangan1

1St Luke's Medical Center Global City Taguig Philippines

Background: The benefit of prophylaxis to prevent the development of antituberculosis drug-induced hepatotoxicity (ATDH) is still unclear. One of the promising hepatoprotectants available is N-acetylcysteine (NAC). We aimed to evaluate the effect of NAC on the prevention of ATDH, on transaminase levels and on time to recovery after hepatotoxicity among patients receiving anti-tuberculosis treatment.

Methods: We searched MEDLINE, PubMed, Embase, and CENTRAL up to 30th October 2023. Randomized controlled trials (RCTs) and case control studies comparing NAC with control were included. Statistical analyses were conducted using RevMan 5.4 software. Risk ratio (RR) and mean difference (MD) with 95% confidence intervals (CI) were used to evaluate the effect of NAC. The quality of included studies was assessed according to Cochrane handbook. Sensitivity analysis was conducted to assess the influence of each study.
Results: A total of 987 patients from 6 RCTs and 1 case control (392 with NAC, 595 with control) were included. Overall, prophylactic NAC significantly reduced the occurrence of ATDHI with a pooled RR 0.39 [CI (0.27, 0.58), p<0.00001]. Patients given NAC also had lower transaminases at 2 weeks anti-tuberculosis treatment. The mean difference between NAC and control for ALT was -40.21 [CI (-65.31, -15.10), p=0.002] and for AST was -33.96 [CI (-57.11, -10.81), p=0.004]. Lastly, NAC shortened the time to recovery after hepatotoxicity with a MD -6.51 days [CI (-8.13, -4.89), p=0.00001].

Conclusions: NAC serves as effective prophylaxis in preventing ATDHI. It has protective effects on transaminase elevation as well as reduces the time to recovery after hepatotoxicity.

Usefulness of a new diagnostic criteria in patients suspected of drug-induced liver injury

Noriyo Yamashiki1, Kanehiko Suwa1, Kazunori Aoi2, Takashi Yamaguchi3, Masao Yamashina1, Katsunori Yoshiida1, Miki Murata1, Toshihito Seki3, Masaaki Shimatani1, Shinji Shimoda2, Makoto Nagamura2

1Department of Gastroenterology and Hepatology, Kansai Medical University Medical Center Osaka, Japan, 2Department of Gastroenterology and Hepatology, Kansai Medical University Osaka, Japan

Background: For the diagnosis of drug-induced liver injury (DILI), DDW-J2004 Workshop criteria has been used for many years in Japan. In this study, usefulness of the new criteria, RECAM (Hayashi PH, et al, DOI: 10.1002/hep.32327), was investigated.

Methods: Patients who were hospitalized for suspected DILI between 2017 and 2022 were enrolled. There were 30 cases suspected DILI with ALT ≥5×upper limit of normal (N) or ALP ≥2×N. Diagnostic performance of DDW-J2004 and RECAM were compared.

Results: Patient age was 63(20-95) years, 9 (30%) were male. Causal drugs were anticancer agent (3), antiviral/antibiotics (3), dermatological (3), herbal medicine (4), and others. Injury pattern was hepatocellular in 22 (64%), cholestatic in 10 (29%), and mixed in 2 (6%). Interpretation by DDW-J2004 and RECAM were highly probable (3, 6), probable (16, 11), possible (9, 12), and unlikely (2, 1). Fairly agreement of 33.7% (kappa 0.34, p<0.01) was observed. The lower scores in RECAM were mainly due to missing values. Twenty-three cases recovered after discontinuation of the causal medication, 6 recovered with corticosteroid therapy, and 1 developed acute liver failure requiring liver transplantation. Later, diagnosis of DILI was denied in 2 cases; one case (DDW-J2004 possible; RECAM possible) coincidentally re-administered the same drug without liver injury. The other case (JDDW2004 probable; RECAM highly likely) showed ANA x 80 and IgG 1.6g/dL. Later the level of IgG increased, and liver biopsy finding was consistent with AIH.

Conclusion: RECAM criteria requires strict differential diagnosis, but may leads to accurate diagnosis.

Dopamine analog inhibits the HBV surface and e antigen expression by upregulation JAK/STAT pathway

XiaoQuan Liu1

1Department of Infectious Diseases, Third Affiliated Hospital of Sun Yat-sen University GuangZhou China

Background: Hepatitis B virus (HBV) infection is a major risk factor for cirrhosis and liver cancer and its treatment has always been challenging. Although several nucleos(t)ide analogs are available for treatment of HBV infection, long-term treatment with these drugs can lead to the emergence of drug-resistant viruses. In order to carry out such combinational therapy against HBV, several new drugs should be developed. We previously expressed and purified the HBV TP-RT with high purity using an E. coli expression system and established an in vitro ε RNA-binding assay system. Then, we used TP-RT in cell-free assays to screen candidate inhibitors from a chemical compound library, and identified, dopamine analog inhibited the HBV DNA, HBV surface antigen (HBsAg) and HBV e antigen (HBeAg) expression level. However, the inhibition of HBsAg and HBeAg mode of action remained unclear. Here, we aimed to identify the mechanism underlying dopamine analog-inhibited HBsAg and HBeAg.

Methods: We used dopamine analog treated AAV-HBV-infected mouse model, HepG2.2.15 and human NTCP-expressing HepG2 cell lines.

Results: We found that dopamine analog inhibited HBsAg and HBeAg expression level in two cell lines; dopamine analog increased the expression level of ISG15 and the JAK-STAT pathway factor STAT1, p-STAT1 and JAK1 expression level; dopamine analog inhibited the HBsAg and HBeAg expression level in AAV-HBV mouse model.

Conclusions: Clarifying the regulatory relationship between the dopamine analog and JAK-STAT/ISG15 pathway is necessary for developing new targets for the clinical treatment of chronic hepatitis.

Background: The treatment goal of chronic hepatitis B (CHB) is HBs antigen (HBsAg) elimination, however it is difficult to achieve the goal with interferon and nucleos(t)ide analogues (NAs). We have developed a nasal administrative therapeutic vaccine containing HBs/ HBcAg mixed viscosity enhancer (CVP-NASVAC). We conducted a clinical trial of CVP-NASVAC against CHB and demonstrated its capacities of HBsAg reduction and anti-HBs induction. In this study, we explored a factor affecting HBsAg reduction.

Methods: Fifty CHB patients (21 with NAs and 29 without NAs) received total 10 doses of CVP-NASVAC via nose. We investigated the rate of HBsAg reduction/loss, IgA- and IgG-type anti-HBs induction. We have developed a nasal administrative therapeutic vaccine containing HBs/HBeAg mixed viscosity enhancer (CVP-NASVAC). We conducted a clinical trial of CVP-NASVAC against CHB and demonstrated its capacities of HBsAg reduction and anti-HBs induction. In this study, we explored a factor affecting HBsAg reduction. We used dopamine analog treated AA V-HBV-infected mouse model.

Results: Fifteen HBsAg patients (21 with NAs and 29 without NAs) received total 10 doses of CVP-NASVAC via nose. We investigated the rate of HBsAg reduction/loss, IgA- and IgG-type anti-HBs induction by CLEIA and ELISA, and HBcAg-specific CTL by ELISPOT.

Results: At the 18 months after CVP-NASVAC administration, HBsAg was reduced to 80.6% compared with baseline in patients with NAs and 86.4% without NAs, and HBsAg loss was observed in 1/21 with NAs and 3/29 without NAs. Anti-HBs was induced in 14.3% (3/21) with NAs and 42.9% (12/28) without NAs. IgA type anti-HBs titer and the number of HBc-specific interferon γ producing CTL were significantly increased after CVP-NASVAC treatment in both with and without NAs. Interestingly, significant correlation was observed...
between the CTL increase and HBsAg reduction in CHB patients with NAs (p<0.005), however no correlation was observed between anti-HBs elevation and HBsAg reduction.

**Conclusion:** HBsAg-specific CTL induction might be an important factor of reducing HBsAg in CHB patients under NAs treatment.

**Highly expressed CTLA4 on B cells defected BCR signal to inhibit the secretion of anti-HBs in CHB**

Shengxia Yin1, Xin Tong1, Yuxin Chen2, Jie Li1, Chao Wu1
1Department of Infectious Diseases, Nanjing Drum Tower Hospital, Affiliated Hospital of Medical School, Nanjing University Nanjing China, 2Department of Laboratory Medicine, Nanjing Drum Tower Hospital, Affiliated Hospital of Medical School, Nanjing University Nanjing China

**Background:** The generation of anti-HBs is lacking in CHB patients. The cause is controversial. B cells activation state has a crucial effect on the secretion level of antibodies. Therefore, B cell status deserves more attention.

**Methods:** Single-Cell RNA-seq analysis was performed in peripheral B cells. Peripheral and liver infiltrated B cells were characterized by flow cytometry. BCR signaling was tested by Ca⁺ flow and WB assay. Aimed to explore the inhibiting role of CTLA4, we did CTLA4-blocking test in vitro. Further, B6-Ighm-KO mice were injected with HBsAg preimmunized CTLA4⁻/⁻ B cell after establishing HBV transduction model and HBV serological indicators were detected. CO-IP assay and proteome analysis was made to explore the downstream proteins of preimmunized CTLA4⁻/⁻ B cell after establishing HBV transduction model and HBV serological indicators were detected. CO-IP assay and proteome analysis was made to explore the downstream proteins of CTLA4.

**Results:** CTLA4 was highly expressed in B cells of CHB patients and more obviously in HBsAg-specific B cells. Moreover, CTLA4 was highly expressed in about 50% of the infiltrating HBsAg-specific B cells. CTLA4 HiB-BSAg ·B cells tended to show activated markers. GO analysis, Ca⁺ flow and WB assay showed that BCR signaling of CTLA4⁻/⁻ B cells was defected. Moreover, CTLA4 blocking could partly restore the defection and make B cells secreted more anti-HBs. In mice model, B6-Ighm-KO mice injected with HBsAg preimmunized CTLA4⁻/⁻ B cells showed decreased level of HBV serological indicators. Proteome assay showed SHIP-1 was the down stream of CTLA4.

**Conclusions:** The circulating and liver infiltrating B cells increased the expression of CTLA4 to defected the BCR signal which might contribute to the deficiency of viral specific humoral response during CHB course.

Abstract Submission No. 100691

**Comprehensive analysis of CHB concurrent with NAFLD : A Proteomics Report Based on Liver Samples**

Xin Tong1, Shengxia Yin1, Chao Wu1, Jie Li1
1Nanjing Drum Tower Hospital, Affiliated Hospital of Medical School, Nanjing University Nanjing China

**Background and Aims:** In recent years, NAFLD has become more prevalent in patients with chronic hepatitis B as the prevalence of obesity and metabolic syndrome has increased. Both diseases can lead to liver fibrosis and even HCC, but the pathogenesis of each disease and CHB concurrent with NAFLD have not been fully elucidated.

Methods: We characterized the protein expression in liver tissues among four groups of people with healthy control, CHB, NAFLD, and CHB concurrent with NAFLD by using proteomic profiling. Based on the obtained DEPs results, further bioinformatics analysis was performed. We also verified the expression of some DEPs in the livers of patients and model mice.

**Results:** We found that accelerated viral clearance in HBV-infected patients with concurrent fatty liver might be associated with an inflammatory response and activation of a large number of metabolic reactions in the organism, while the level of hepatic steatosis was associated with abnormalities in fatty acid degradation, glycolysis/glucogenesis and others, however the prognosis of CHB concurrent with NAFLD is probably not optimistic, which could be associated with the expression of ACAT1, ACY1, SERPINB3, MTCH2, ALDH2, ECHS1, S100A7 and LRP6.

**Conclusion:** The prognosis of CHB complicated with NAFLD may not be optimistic compared with that of hepatitis B and NAFLD alone, which is closely related to the differential expression of certain proteins in the liver after the complication of the two diseases. Our study provides new insights into the disease development and clinical mechanisms of CHB and NAFLD.

Abstract Submission No. 100855

**MiRNA106b-3p down regulates PCGF3 and inhibits cell metastasis in HBV-related hepatoma carcinoma**

Tao Shen1, 2, 4, Jing Chen1, 2, Qi Yin1, 2, Jainqiong Wang3, Chaohui Chen1, 2, Li Li1, Shiheng Xiu1, 2
1Department of Pulmonary and Critical Care Medicine, Yunnan Provincial Key Laboratory for Clinical Virology, Institute of Basic and Clinical Medicine, The First People's Hospital of Yunnan Province Kunming China, 2Kunming University of Science and Technology Kunming China, 3Department of Clinical Laboratories, The First People's Hospital of Yunnan Province Kunming China, 4Department of Infectious Diseases and Hepatic Disease, Yunnan Province Innovation Team of Intestinal Microecology Related Disease Research and Technological Transformation, the First People's Hospital of Yunnan Province Kunming China

**Background:** MicroRNA-106b (miRNA-106b) has been shown to play a paradoxical role in disease progressing from different studies. However, the specific role of miRNA106b-3p in hepatocellular carcinoma and the underlying mechanism remains unclear.

**Method:** Huh7 cell transient transfected with HBV C2 subgenotype plasmid was co-cultured with miRNA-106b-3p mimics. HBsAg level was detected using Elisa assay. Target genes that potentially bind to miR-106b-3p were predicted using TargetScan software. Target analysis was conducted via a dual-luciferase reporter assay. Q-PCR was used to detect expression level of target genes. Scratch assay was performed to evaluate cell migration. Transwell assays was used to evaluate cell invasion. Western blot was used to detect the PI3K/AKT signaling pathway-related proteins.

**Results:** Huh-7 HBV/C2 cells co-cultured with miRNA-106b-3p mimics was significantly increased with miRNA-106b-3p expression and down-regulated with HBsAg level. MiR-106b-3p overexpression significantly decreased the luciferase activity of wild-type PCGF3 3′-UTR, but no significant effect on the luciferase activity of mutant PCGF3 3′-UTR. MiR-106b-3p mimic can dramatically decrease the expressions of PCGF3 mRNA and protein in Huh7-HBV/C2 cells. In addition, the migration and invasion ability of Huh7-HBV/C2 cells was significantly decreased and the PI3K-AKT pathway was inhibited by miRNA-106b-3p mimics.

Abstract Submission No. 100855
O-0068
Conclusion: This study revealed that miR-106b-3p could down-regulate the expression of PCGF3 and inhibit the activation of PI3K/AKT signaling pathway, thereby preventing HCC metastasis.

Funding: This work was supported by the Yunnan Provincial Science and Technology Department (2019FAA030); in part by the National Natural Science Foundation of China (82160384); and in part by the Yunnan Health Commission (L2019003).

Abstract Submission No. 101155
O-0069

The differentiation of Treg and Th17 cells in patients with chronic hepatitis B in different stages

Hang Le1, Huy Nguyen2, Hoa Pham1

1University of Medicine and Pharmacy at Ho Chi Minh City Ho Chi Minh Vietnam, 2School of Tropical Medicine and Global Health, Nagasaki University Nagasaki Japan

Regulatory T (Treg) and T helper 17 (Th17) cells modulate the immune response in chronic hepatitis B virus infection by promoting immune tolerance, restricting liver damage, stimulating inflammatory responses, and inducing hepatocyte injury. These cells act by signaling immune tolerance, restricting liver damage, stimulating inflammatory response in chronic hepatitis B virus infection by promoting immune response. The differentiation of Treg and Th17 cells in patients with chronic hepatitis B in different stages were measured by flow cytometry, and the mRNA levels of transcription factors do not correlate with the percentage of Treg and Th17 cells. Our study aimed to observe the percentages of Treg and Th17 cells, as well as their mRNA levels of Foxp3 and RORγt, in chronic hepatitis B (CHB)-infected groups and CHB patients experiencing hepatitis flare (HF). We recruited 159 participants, including 137 CHB-infected cases and 22 healthy controls (HC) from Ho Chi Minh City. CHB cases were divided into three groups: HBeAg+ CHB infection (e+CHBI, n=52), HBeAg+ CHB (e+CHB, n=24), and HF (n=61). Treg and Th17 cells were measured by flow cytometry, and the mRNA levels of Foxp3 and RORγt were analyzed by Realtime PCR. The percentages of Treg, Th17, and a special subset - IL17A(+)Foxp3(+)Treg cells - were significantly higher in the HF group compared to the e+CHBI group. Meanwhile, there was no significant difference in the mRNA levels of Foxp3 and RORγt in CHB groups. These findings reveal that these immune cells increase with the severity of the liver injury, and the mRNA levels of transcription factors do not correlate with the percentages of their cells. Our results explain the diversity of T cells and their subsets in the immune response in CHB and suggest that the new subset should be further investigated as a specific tool in the HBV immune response.

Adenosine sulfamate analogs inhibit HBV RNA synthesis and accelerate the decay of viral transcripts

Bingqian Qu1, Maike Herrmann1, Saskia Mönch1, Renate König1, Richard J.P. Brown8

1Paul-Ehrlich-Institut Langen Germany, 2Ruhr University Bochum Bochum Germany

Background: The neddylation pathway is required for HBV replication. Targeting neddylation inhibits both HBV gene transcription and surface antigen expression in preclinical models. However, the underlying mechanism of neddylation modulation and HBV gene transcription remains unclear.

Methods: Two adenosine sulfamate analogs (ASAs) were evaluated for their ability to target host components of the neddylation pathway and inhibit HBV gene transcription in susceptible cells, in addition to explanted primary human hepatocytes (PHHs) from multiple donors. Nascent transcript production was determined by click chemistry. RNA sequencing of HBV-infected PHHs determined the effects of ASAs on viral and host transcriptomes.

Results: Both ASAs, MLN4924 and TAS4464, reduced the expression of NAE1, Ubc12, Cul4A and neddylated cullins in PHHs. Upon SMC5/6 gene knockdown or HBx absence, the inhibitory effects of ASAs on viral transcription were alleviated. To further investigate the mechanism, 5-ethyl-uridine was incorporated into infected HepG2-NTCP cells, allowing the detection of nascent transcripts. MLN4924 and TAS4464 reduced the synthesis of HBV transcripts by 60% and 74%, respectively. Furthermore, compared to DMSO treatment (>24 hours), ASAs accelerated the decay of subgenomic transcripts (t1/2 = 10.8 and 14.2 hours) in HepAD38 cells. Remarkably, RNA-sequencing results showed that ASAs modulate host transcriptomes upon HBV infection in PHHs by selectively regulating a small cluster of host genes.

Conclusions: We demonstrate that ASAs reduce the protein expression of host components of the neddylation pathway, inhibit HBV RNA synthesis and accelerate viral transcript decay. ASAs have potential for future development and repurposing as a novel class of anti-HBV therapeutic.

Abstract Submission No. 101227

Multi-Omics Panoramic Analysis of HBV Integration in the HBV-Integrated Cell Line PLC/PRF/5

Guwen Guan1, Abudurexiti Abulaiti1, Danjuan Lu1, Zhiqiang Gu1, Ting Zhang1, Fengmin Lu1, Xiangmei Chen1

1Department of Microbiology & Infectious Disease Center, School of Basic Medical Sciences, Peking University Beijing China

Background: The clearance or transcriptional silencing of integrated HBV DNA is crucial for achieving a functional cure in patients with chronic hepatitis B (CHB) and reducing the risk of hepatocellular carcinoma (HCC) development. The PLC/PRF/5 cell line is commonly used as an in vitro model for studying HBV integration. In this study, we employed a range of multi-omics techniques to gain a panoramic understanding of the characteristics of HBV integration in PLC/PRF/5 cells.

Methods: Transcriptome long-read sequencing was conducted to analyze characterize the transcriptional activity of different HBV DNA integrations in PLC/PRF/5 cells. Additionally, data pertaining to epigenetic regulation such as whole-genome bisulfite sequencing (WGBS), ChIP-seq, and ATAC-seq were collected to investigate the potential mechanisms associated with the transcriptional regulation of integrated HBV DNA.

Result: Our findings indicate that transcriptional activity of integrated HBV DNA in PLC/PRF/5 cells is influenced by methylation levels of the surrounding host genome near the integration site. The result indicated that elevated methylation of the adjacent host genome adversely impacts transcription activity of integrated HBV DNA. Furthermore, we observed a positive association between histone modification H3K4me3 and the transcription of integrated HBV DNA. These results suggest that host may regulate transcriptional activity of integrated HBV DNA through DNA methylation and histone modifications. Potentially leading to the silencing of integrated HBV DNA.

Conclusion: Our study brought a better understanding on the transcriptional regulation of integrated HBV DNA. This knowledge can be valuable in the development of novel strategy for functional cure of CHB.
IGF2BP1 promotes HBV replication via regulating HBV RNA stability in an m6A-dependent manner

Deyao Li¹, Jing Ning², Danjuan Lu¹, Fengmin Lu¹, Xiangmei Chen¹
¹Department of Microbiology & Infectious Disease Center, School of Basic Medical Sciences, Peking University Beijing China, ²Department of Gastroenterology, Peking University Third Hospital Beijing China

Background & aims: Hepatitis B virus (HBV) infection is the primary cause of chronic hepatitis B, cirrhosis, and hepatocellular carcinoma world widely. During HBV replication, HBV RNA undergoes post-transcriptional regulation by host cells which primarily relies on various host RNA binding proteins. However, the detailed mechanisms underlying post-transcriptional regulation of HBV RNA remain unknown. Herein, we investigated the role of RNA binding protein IGF2BP1 in the process of HBV replication.

Methods: The host proteins associated with HBV Dane particles was analyzed by mass spectrometry. Gene silencing and ectopic overexpression were used to detect the function of IGF2BP1 in regulating HBV replication. RNA turnover, RNA pull-down, and RNA immunoprecipitation assays were used to investigate the stability and binding between IGF2BP1 and HBV RNAs.

Results: Our study identified IGF2BP1 as an RNA binding protein that can be encapsulated into HBV Dane particles. According to the HBV replication cell model, the HBV infection cell model, and the HBV replication mouse model, we confirmed that IGF2BP1 promotes HBV replication. To elucidate the underlying mechanism, we found that IGF2BP1 enhanced the stability of all five HBV RNAs through its KH domain. IGF2BP1 recognized and bound to m6A modification sites on HBV RNAs, consequently promoted HBV RNA expression. This increased HBV RNA expression led to elevated protein expression and the formation of rcDNA, ultimately enhancing HBV replication.

Conclusions: Our study demonstrated IGF2BP1 as a critical host factor in enhancing the stability of HBV RNAs and facilitating HBV replication which provided a novel target for the development of anti-HBV drugs.

Deep sequencing analysis of HBV evolution in elderly cases of interspousal transmission

Jun Inoue¹, Takehiro Akahane², Yutaka Miyazaki³, Masashi Ninomiya¹, Akitoshi Sano¹, Mio Tsuruoka¹, Kosuke Sato¹, Masazumi Onuki¹, Satoko Sawahashi¹, Keishi Ouchi¹, Atsushi Masumune¹
¹Department of Gastroenterology, Tohoku University Hospital Sendai Japan, ²Japanese Red Cross Ishinomaki Hospital Ishinomaki Japan, ³Tohoku Kosai Hospital Sendai Japan

Background/Aim: Hepatitis B virus (HBV) is transmitted within a family, but an interspousal transmission in elderly cases is rare. To clarify the dynamics of HBV quasispecies in such cases, we performed long-read deep sequencing of the HBV preS1/preS2/S domain in two elderly couples of HBV transmission from wife to husband.

Methods: Using serum samples from two male patients with acute hepatitis (AH1: 67 years old, AH2: 71 years old) and their HBV carrier wives (CH1: 67 years old, CH2: 66 years old), HBV full genome sequences were determined by direct sequencing. In addition, a long-read deep sequencing was performed with PacBio Sequel II using preS1/preS2/S domain amplicons.

Results: As a result of whole genome direct sequencing, AH1 was 98.0-99.2% identical to CH1, and AH2 was 98.5-99.5% identical to CH2. The identity between AH1 and AH2 was 96.9%. When a phylogenetic tree analysis was performed using the long-read deep sequences, it was shown that CH1 and CH2 had heterogeneous clones but AH1 and AH2 had relatively homogeneous clones. It was also suggested that the transmitted viral clones might be distinct from the major populations in the HBV carriers. We speculated that the major population in the carriers did not fit to the spouses and this might be one of the reasons why the transmission had not occurred during younger age.

Conclusion: Deep sequencing analyses revealed clonal population changes during HBV transmission.

Knowledge, Attitudes and Practices (KAP) of Adult Filipinos towards Viral Hepatitis

Viral hepatitis is a major public health burden worldwide. The objective is to focus on patients’ knowledge, attitudes, and methods regarding viral hepatitis B and C to improve awareness, attitudes, and procedures related to viral hepatitis, leading to better prevention and management of the disease. A validated descriptive, cross-sectional, self-reported questionnaire on knowledge, attitudes and practices (KAP) relating to hepatitis B and C was administered at the outpatient department in a tertiary hospital. Data were analyzed and compared with mean scores from 2015-2023. Majority of the participants (44%) were between 41-60 years old, residing in Metro Manila (81%), high school graduates (53%) and unemployed (64%) and 81% having a monthly income of less than 200 USD (Php 10,000.00). There was an increasing mean KAP score towards hepatitis B and C from 2015 to 2017, with a decrease in the mean KAP scores in 2023. There were also no significant differences in the mean KAP scores except for practice scores in terms of place of residence (p=0.026), and knowledge and practice scores in terms of place of residence (p=0.026 and 0.03 respectively). With most medical services directed to contain the expanding COVID-19 pandemic, viral hepatitis programs face several challenges. The COVID pandemic has widened the gap in the KAP towards hepatitis preventive practices and knowledge. Targeted health education programs promoting disease awareness should be intensified to eradicate viral hepatitis as a global health concern.

IFN-γ Th1 promotes HBsAg loss by activating intrahepatic TRM through inducing M1 polarization

Lili Wu1, Bingleiang Lin1, Zhiliang Gao4
1Third Affiliated Hospital of Sun Yat-sen University Guangzhou China

Background: The immune mechanism of ALT elevation and HBsAg loss during pegylated interferon (PEG IFN) therapy remains to be elucidated.

Methods: Eight-two NA (nucleos(t)ide analog) treated Chronic hepatitis B (CHB) patients sequentially received add-on PEG IFN treatment for less than 96 weeks. 41 patients got HBsAg < 0.05 IU/ml (cured group) within 48 weeks. Blood samples were collected from all patients for research. Liver tissue from 14 CHB patients was used to detect inflammatory markers. Liver perfusate from healthy individuals or chronic HBV-infected individuals was used for mechanism validation. THP-1, Jurkat and HepG2.2.15 cell lines were used in vitro experiments.

Results: Serum and intrahepatic levels of Th1 cell-associated chemoattractants (CXCL9, CXCL10, CXCL11) and the proportion of Th1 cells in peripheral blood kept higher in the uncured group. But the proportion of IFN-γ Th1 cells was higher in the cured group (0-24 weeks), the latter was linearly correlated with HBsAg decline and ALT levels during treatment. However, weak association was found between CD8+ T cells and HBsAg loss. Serum from cured patients induced a higher proportion of M1 (CD68+CD86+ Macrophage) cells compared to uncured patients. Polarization of IFN-γ Th1 cells as well as M1 macrophages could be induced by IFN-α. M1 polarization of intrahepatic Kupffer cells promoted HBsAg loss by enhancing the effector function of tissue-resident T cells with an elevation of ALT levels.

Conclusions: IFN-γ Th1 promotes HBsAg loss by activating intrahepatic resident memory T cells through inducing M1 macrophage polarization.

Anti-PD-1 antibody combined with ETV and Peg-IFN-α enhances anti-HBV efficacy in AAV-HBV mice

Taiyu He1, Huanyu Xiang1, Min Chen1, Mingli Peng1, Peng Hu1, Dachuan Cai1, Yinghua Lan1, Dazhi Zhang1, Hong Ren1
1Department of Infectious Diseases, Key Laboratory of Molecular Biology for Infectious Diseases (Ministry of Education), Institute for Viral Hepatitis, the Second Affiliated Hospital, Chongqing Medical University Chongqing China

Background: This study aimed to find a safe and more effective therapeutic strategy for hepatitis B virus (HBV) infection by combining anti-PD-1 antibody (α-PD-1), entecavir (ETV) and pegylated interferon-alpha (PEG-IFN-α).

Methods: A 4-week treatment was conducted in an adeno-associated virus (AAV)-HBV mouse model. To evaluate safety, efficacy and immune response, various indicators were compared between model control, ETV, ETV+αPD-1, ETV+αPD-1/Peg-IFN-α, and ETV+αPD-1/Peg-IFN-α groups.

Results: All groups had stable weight, alanine aminotransferase and aspartate transaminase levels during treatment, and similar liver necroinflammatory activity (P>0.05). After 4-week treatment, plasma HBsAg decreased most significantly in ETV+αPD-1/Peg-IFN-α group ([Mean: 3.99 log10 vs. 4.36 log10 (Model control group), P<0.023]; Plasma HBV DNA and HBsAg, and hepatocyte HBsAg positivity rates significantly decreased, but no statistically significant difference was found between groups at 4 week. Myeloid, NK, B and T cell responses were detected. Notably, after 4-week treatment, frequencies of HBV surface-specific IL-4+/IL-21+/IFN-γ/TNF-α+ CD8+ T cells increased significantly in liver and blood in ETV+αPD-1/Peg-IFN-α group (P<0.05); Frequencies of PD-1+CD8+ T cells in liver and CD8+ effector memory T (TEM) cells in spleen increased significantly in ETV+αPD-1/Peg-IFN-α group, and the former positively correlated with frequencies of CD38+CD8+ TEM cells (P<0.05); Frequencies of circulating T follicular helper 1 (cTfh1) cells increased more prominently in ETV+αPD-1/Peg-IFN-α and ETV+αPD-1/Peg-IFN-α groups. Furthermore, HBsAg decrease value correlated with frequencies of above surface-specific IL-21+CD8+, PD-1+CD8+ and CD8+ TEM cells, and cTfh1 cells (P<0.05).

Conclusions: ETV+αPD-1/Peg-IFN-α sequentially combined therapy reduces HBsAg levels safely and more effectively, whose efficacy may be related to enhanced T cell responses.

Serum N-Glycan for Diagnosing Liver Fibrosis in Chronic Hepatitis B Patients with Normal ALT Levels

Yi-Qi Liu1, Lin Wang2, Chi Zhang1, Xue-En Liu3, Hong Zhao1, Hui Zhuang3, Gui-Qiang Wang1
1Department of Infectious Disease, Peking University First Hospital Beijing China, 2Department of clinical laboratory, Beijing CHAO-YANG Hospital Beijing China, 3Department of Microbiology & Center of Infectious Diseases, Peking University Health Science Center Beijing China

Background: The aim of this study was to explore the role of serum N-glycomic-derived models in diagnosing significant liver fibrosis and cirrhosis in 285 chronic hepatitis B (CHB) patients with normal (<40 IU/L) alanine aminotransferase (ALT) levels.

Methods: Liver biopsy stages were assessed using the Ishak scoring system. Serum N-glycan profiles were tested using DNA sequencer-
assisted fluorophore-assisted carbohydrate electrophoresis (DSA-FACE). A machine learning method, random forest (RF) analysis was adopted to construct more ideal serum N-glycan models in order to distinguish significant liver fibrosis and cirrhosis.

**Results:** From Jan 2013 to Dec 2020, 285 CHB patients were enrolled, 63.86% (182/285) and 16.49% (47/285) of patients had significant liver fibrosis and cirrhosis, 4.91% (14/285) of patients had significant inflammation. The diagnostic efficiency of the serum N-glycan RF model constructed for distinguishing significant liver fibrosis (F3; RF-A model) was excellent (area under receiver operating characteristic (AUROC): 0.94), and the coincidence rate of the serum N-glycan RF-A model compared with liver biopsy was 90.45%. The diagnostic AUROC of the serum N-glycan RF model constructed for distinguishing liver cirrhosis (F5; RF-B model) was 0.97, and the coincidence rate was 88.94%.

**Conclusions:** The diagnostic efficiency of the constructed serum N-glycan models (RF-A and RF-B) was similar to that of liver stiffness measurement (LSM), the fibrosis index based on the four factors (FIB-4), and the aspartate aminotransferase-to-platelet ratio index (APRI). Serum N-glycan models are promising markers for the differentiation of significant liver fibrosis and cirrhosis in CHB patients with normal ALT levels.

**Alcohol induced dendritic cell and its exosome promotes specific T cell immunity in HBV infection**

Hongbo Shi1,2, Xinzong Miao1,2, Chaoan Liu1,2,3, Honglin Shi1,2, Fang Liu4, Yingmin Ma1,2, Xiaoshuang Zhou1

1Beijing Institute of Hepatology, Beijing Youan Hospital, Capital Medical University, Beijing Beijing China, 2Beijing Engineering Research Center for Precision Medicine and Transformation of Hepatitis and Liver Cancer Beijing China, 3Department of Nephrology, Shanxi Provincial People’s Hospital, The Affiliated People’s Hospital of Shanxi Medical University Shanxi Province China

**Background:** Dendritic cell (DC) plays a crucial role in the immune system and its function was found to be significantly impaired in patients with chronic hepatitis B. Dendritic cell derived exosome (DEX) is an extracellular vesicle secreted by DC and has the same or similar immune function as DC. Therefore, this study investigated the therapeutic role of DC and DEX in HBV infection.

**Methods:** We systematically investigated the functional effects of alcohol and HBV infection on DC and DEX, and co-cultured DC and DEX induced by alcohol with lymphocytes from HBV transgenic mice and patients with chronic hepatitis B to observe the T-cell immune response.

**Results:** Alcohol effectively stimulated the maturation of mouse bone marrow-derived dendritic cells (BMDCs) and DCs from HBV patients, but had no significant effect on the DC2.4 cell line. HBV infection inhibited the activation and maturation of DC and DEX. More importantly, in HBV transgenic mice and chronic hepatitis B patients, alcohol-induced DCs effectively promoted specific T-cell immunity, and DEXs were able to exert the same effects as DCs.

**Conclusions:** Our findings provide a new and effective way to stimulate DC maturation. In the future, DEX may substitute for DCs as a new therapeutic approach for patients with chronic hepatitis B.

**Kinetics of iTACT-HBcrAg and -HBsAg assays in chronic hepatitis B patients with HBsAg seroclearance**

Takanori Suzuki1, Kentaro Matsuura1, Takehisa Watanabe2, Takeshi Matsui1, Shintaro Ogawa2, Hayato Kawamura1, Kayoko Kuno1, Kei Fujiwara1, Shunsuke Nojiri1, Hiromi Kataoka1, Yasuhito Tanaka2

1Department of Gastroenterology and Metabolism, Nagoya City University Graduate School of Medical Sciences Nagoya Japan, 2Department of Gastroenterology and Hepatology, Kumamoto University Kumamoto Japan, 3Center for Gastroenterology, Teine-Kekiinkai Hospital Sapporo, Hokkaido Japan

**Objectives:** Two novel assays have been developed, iTACT-hepatitis B core-related antigen (iTACT-HBcrAg) and iTACT-hepatitis B surface antigen (iTACT-HBsAg) assays. We investigated the longitudinal profiles of iTACT-HBcrAg and -HBsAg in patients with HBsAg seroclearance (SC) (<0.05 IU/mL).

**Methods:** This study comprises 60 HBV-infected patients with HBsAg SC, 27 in chronic hepatitis/liver cirrhosis (CH/LC) group and 33 in inactive carrier (IC) group. Longitudinal profiles of iTACT-HBcrAg and -HBsAg were examined using stored serum samples.

**Results:** The median period from HBsAg SC to iTACT-HBcrAg loss or to the last observation was longer in the CH/LC group than the IC group (39 vs. -3 months, P = 0.004), but this tendency was not observed in that by iTACT-HBsAg. Comparing the times of iTACT-HBcrAg and -HBsAg loss, the rate of patients who lost HBcrAg first was significantly higher in the IC group (P = 0.008). The cumulative incidence rate of iTACT-HBcrAg loss after HBsAg SC was higher in the IC group that the CH/LC group (P = 0.002), but there was no difference in the cumulative incidence of iTACT-HBsAg loss after HBsAg SC between the IC and CH/LC groups.

**Conclusions:** Patients in the CH/LC group had higher rates of detectable iTACT-HBcrAg than those in the IC group after HBsAg SC, suggesting that the presence of HBcrAg possibly contribute to the progression of chronic hepatitis B.

**Effects of Vitamin D and Calcium on Bones in Chronic Hepatitis B Patients Treated with TDF**

THANAPAT ATTAKHITMONGKOL1, Wimolrak Bandidinayamoni1, Supot Nimmong1, Watcharasak Chotiyaputta1, Siwaporn Chainuvati1, Phunchai Charatcharoenwiithaya1, Taweetsak Tanwande1

1Division of Gastroenterology, Department of Medicine, Faculty of Medicine Siriraj Hospital, Mahidol University Bangkok Thailand

**Background:** Tenofovir disoproxil fumarate (TDF) is an important drug to treat chronic hepatitis B (CHB) patients. However, long-term TDF therapy decreases renal function and bone mineral density (BMD).

**Objective:** To compare bone turnover markers, BMD, and renal function in CHB patients treated with TDF who received vitamin D3 and calcium supplements and those who did not receive supplement.

**Methods:** This open-label prospective, randomized trial was conducted in patients with CHB treated with TDF who were randomized to the vitamin D3 and calcium supplement group (n=32) and no supplement group (control group) (n=32) for 48 weeks.

**Results:** At baseline, the mean age was 54.2 years, 57.8% were male, and 17.2% had cirrhosis. Demographic data were similar in both groups, except body mass index, AST, and ALT were higher in the
control group. At 48 weeks, there were no differences in parathyroid hormone, serum creatinine, procollagen-I N-terminal peptide, and tubular reabsorption of phosphate in both groups. The BMD T score of the total hip did not decrease in the supplement group but significantly decreased in the control group. The C-terminal telopeptide of type I collagen increased in only the control group. Subgroup analysis was performed in participants with low baseline vitamin D, the result showed that the median difference in the T score for the total hip in the supplement group also showed a smaller decrease than in the control group.

Conclusions: In CHB patients treated with TDF, supplementation with vitamin D2 and calcium for 48 weeks can prevent loss of BMD.

Unawareness of hepatitis B infection and severity of hepatocellular carcinoma

Kuan-I Lee1, Po-Cheng Liang2, Po-Yau Hsu1,2, Tyng-Yuan Jang1,2, Yu-Ju Wei1, Ching-I Huang2,4, Ming-Yen Hsieh2, Zu-Yau Lin1,2, Ming-Lun Yeh5, Chung-Feng Huang3, Jee-Fu Huang6, Chia-Yen Dai7, Wan-Long Chuang6, Ming-Lung Yu1,4,5,3

1School of Medicine, College of Medicine, Kaohsiung Medical University Kaohsiung Taiwan, 2Division of Hepatobiliary, Department of Internal Medicine, Kaohsiung Medical University Hospital Kaohsiung Taiwan, 3School of Medicine, College of Medicine and Center of Excellence for Metabolic Associated Fatty Liver Disease, National Sun Yat-sen University Kaohsiung Taiwan

Background: Unawareness of hepatitis B virus (HBV) infection and lack of surveillance may serve as major barriers to HBV control and contributors to severe hepatocellular carcinoma (HCC) at presentation. This study evaluated the risk of HBV unawareness and its relationship with HCC severity.

Methods: This retrospective study was conducted in a tertiary hospital in Taiwan. Patients with HBV-related HCC diagnosed from 2011 to 2021 were enrolled. The demographic, clinical, and HCC characteristics were collected and compared between patients with HBV unawareness and awareness with and without surveillance.

Results: Of 501 HBV-related HCC patients enrolled, 105 (21%) patients were unaware of HBV infection at the time of HCC diagnosis. Patients with HBV unawareness were significantly younger and had poorer liver function than those with HBV awareness. Patients with HBV unawareness also had a significantly higher rate of detectable HBV DNA and an advanced stage of HCC. Patients with HBV unawareness and awareness without surveillance shared similar clinical characteristics with more severe HCC status. Further regression analysis demonstrated that HBV awareness with periodic surveillance was associated with early-stage HCC. Meanwhile, we observed that there was no change in the proportion of HBV awareness over the past 10 years.

Conclusions: Patients with surveillance also had better HCC survival than patients without surveillance or unawareness. HBV unawareness and lack of regular surveillance correlated with advanced HCC at presentation. Efforts to improve HBV education, disease awareness, and HCC surveillance are needed.

STOPPING ORAL THERAPY IN CHRONIC HEPATITIS B USING HBsAg THRESHOLDS: METAANALYSIS & META-REGRESSION

Seng Gee Lim1, Ada, Ee Der Teo1, Edwin, Shih-Yen Chan2, Wah Wah Phyo1, David, Hsing Yu Chen1, Carol Anne Hargreaves1

1National University Health System Singapore Singapore, 24Centre for Quantitative Medicine, Duke-NUS Singapore Singapore, 3Data Analytics Consulting Centre, Faculty of Science, National University of Singapore Singapore

Background and aims: Recommendations for stopping nucleoside analogue (NA) therapy in HBeAg-negative Chronic Hepatitis B (CHB) are unclear. End-of-treatment quantitative HBsAg (EOT-qHBsAg) thresholds <100IU/ml or <1000IU/ml have been proposed as stopping criterion. We assessed this by meta-analysis and meta-regression.

Design: We searched PubMed, EMBASE and conference abstracts for studies of HBeAg-negative CHB NA discontinuation. Extracted studies were analysed for risk-of-bias, pooled risk of HBsAg loss, virological (VR) and biochemical relapse (BR). Significant heterogeneity (I²) was addressed by subgroup analysis and random-effects meta-regression with known important covariates, including EOT-qHBsAg thresholds, ethnicity, duration of therapy and followup.

Results: We found 24 papers (3732 subjects), 9 low, 14 moderate and one with high risk of bias. The pooled risks of HBsAg loss, VR and BR for stopping therapy at EOT-qHBsAg<100IU/ml were 41.8%, 33.4% and 17.3%, versus 4.6%, 72.1% and 34.6% respectively for EOT-qHBsAg≥100IU/ml. The pooled risks of HBsAg loss, VR and BR for stopping therapy at EOT-qHBsAg<1000IU/ml were 22.0%, 52.7% and 15.9%, versus 3.4%, 63.8% and 26.4% respectively for EOT-qHBsAg≥1000IU/ml. Multivariable analysis for HBsAg loss showed ethnicity, followup duration and EOT-qHBsAg<100IU/ml explained 85% of the variance in heterogeneity; Asians with EOT-qHBsAg<100IU/ml had 28.2%, while Caucasians with EOT-qHBsAg≥100IU/ml had 38.4% HBsAg loss. Multivariable analysis showed EOT-qHBsAg<100IU/ml and other covariates only explained 43% and 63% of the variance in heterogeneity for VR and BR respectively, suggesting that other factors are also important for relapse.

Conclusions: While EOT-qHBsAg thresholds, ethnicity and followup duration strongly predict HBsAg loss, this is not true for VR and BR, hence stopping NA therapy should be considered cautiously.

Abstract Submission No. 100203

The correlation between Interleukin-6 and the progression of chronic Hepatitis B

MOHAMED MAHOOBALI

1ADVANCED MEDICAL AND DENTAL INSTITUTE(AMDI) GEORGETOWN Malaysia

INTRODUCTION: Hepatitis B virus (HBV) is a dreadful virus with the potential to cause human liver diseases such as self-limiting acute hepatitis, chronic hepatitis, fulminant hepatic failure, liver cirrhosis and hepatocellular carcinoma (HCC). These complications result from an immune response of the host that affects both outcome and disease progression, rather than a direct cytopathic effect. Cytokines have been shown to be engaged in regulating hepatocyte functions, and play an important role in HBV infection immunopathogenesis.

METHODS: About 52 subjects ranging from 18 years old to 80 years old who were diagnosed with HBV were recruited into the studies. Their venous blood was taken and centrifuged at 4500rpm for 5
minutes to separate the blood components. The patient’s sera were withdrawn and divided into two aliquots and kept in a special fridge with a temperature of −20 to −70 degrees. The first group of sera were subjected to a hybrid capture, tube-based signal amplification using HBV Digene Hybrid-Capture I, Digene Corporation, USA. While the second group of sera were subjected to a sandwich-ELISA test using LEGEND MAX Deluxe set human IL-6 kit to quantify the IL-6 levels. Both data were recorded and analysed using IBM SPSS version 26 software.

RESULTS: We found that there was a direct correlation between the severity of HBV viral load and the level of IL-6. The more severe the infection, the higher the IL-6 level (P=0.05) taking the mean value of IL-6 as 132.6pg/ml. Demographical data distributions showed that men, aged between 40 and 60 years old and healthcare workers were the risk factors to develop chronic HBV. A linear scatter plot was derived between the levels of IL-6 and HBV viral load. Pearson correlation coefficient showed a linear correlation between the two variables. The patient’s ALT enzyme was used to stratify the severity of the liver functions. Higher levels of IL-6 were detected in the subjects with HBV for longer than 6 months which proved that IL-6 levels correspond to the chronicity of the disease.

CONCLUSION: IL-6 is a vital mediator of inflammation and the acute phase response of the liver. Our studies proved that serum IL-6 levels were positively correlated with HBV disease severity and chronicity. Thus, IL-6 may be a useful indicator of disease activity and therapeutic efficacy in patients suffering from hepatitis B.

Establishment of a predictive model of myelosuppression in patients with CHB treated with Peg-IFN

jiwei fu1, Xiaoping Wu1

1The First Affiliated Hospital of Nanchang University Nanchang China

Objective: The aim of this study was to explore the risk factors for myelosuppression in chronic hepatitis B patients with peginterferon and establish a risk prediction model.

Methods: A total of 208 patients with chronic hepatitis B who were treated with peginterferon in the infection Department of the First Affiliated Hospital of Nanchang University from December 2019 to December 2021 were selected and divided into the modeling group (153 cases) and the verification group (55 cases) according to a ratio of about 3:1. Patients with degree II and above myelosuppression after 1 dose of interferon therapy were defined as myelosuppression group, and the rest were normal group. The risk factors of myelosuppression were discussed by multivariate logistic regression, and the prediction model was established and verified internally.

Results: The results of multi-factor logistic regression analysis and prediction model establishment show: BMI (OR=0.896, 95%CI 0.772-0.979, P=0.021), leukocyte (OR=0.704, 95%CI 0.508-0.976, P=0.035) and globulin (OR=0.904, 95%CI 0.823-0.992, P=0.034) was an independent factor of myelosuppression in CHB patients treated with peginterferon. Calculation formula: Logit (P) = In[P/(1-P)] = -0.14×[BMI (Kg/m2)] -0.351 ×[WBC (x10^9/L)] -0.101 ×[GLB (g/L)] + 7.606; The AUC of the modeling group was 0.732, P=0.001(Figure 1); The AUC of the verification group was 0.762, P=0.001(Figure 2).

Conclusion: Low BMI, low white blood cell and low globulin at baseline were independent risk factors for myelosuppression in CHB patients treated with peginterferon, and a risk prediction model was established, which provided a basis for early identification of myelosuppression prone patients in clinical work and active preventive measures.

Tenofovir disoproxil fumarate raises long-term fracture risk in elderly chronic hepatitis B patients

Terry Cheuk-Fung Yip1, 2, 3, Jimmy Che-To Lai1, 2, 3, Tsz-Fai Yam1, 2, Yee-Kit Tse1, 2, 3, Vicki Wing-Ki Hui2, 3, Mandy Sze-Man Lai1, 2, 3, Henry Lik-Yuen Chan4, Vincent Wai-Sun Wong5, 2, 3, Grace Lai-Hung Wong6

1Medical Data Analytics Centre, The Chinese University of Hong Kong Hong Kong Hong Kong, 2Department of Medicine and Therapeutics, The Chinese University of Hong Kong Hong Kong, 3State Key Laboratory of Digestive Disease, The Chinese University of Hong Kong Hong Kong Hong Kong, 4Department of Internal Medicine, Union Hospital, Hong Kong Hong Kong Hong Kong

Background: The use of tenofovir disoproxil fumarate (TDF) is associated with a reduction in bone mineral density. However, data on clinical bone fractures remain limited. We evaluated the impact of TDF compared to entecavir on fracture risk in elderly patients with chronic hepatitis B (CHB).

Methods: Patients with CHB aged ≥60 years receiving entecavir or TDF between January 2008 and December 2022 were identified using a territory-wide database in Hong Kong. The risk of incident fracture in entecavir- and TDF-treated patients before and after month 24 were compared after propensity score (PS) matching.

Results: 41,531 patients with CHB (mean age 69.8±7.8 years, 61.6% male) receiving entecavir (n=39,897 [96.1%]) and TDF (n=1,634 [3.9%]) were analysed. At a median follow-up of 25.3 (9.1-58.5) months, 1,733 (4.2%) patients developed incident fracture. Patients with incident fracture were more likely to have diabetes, hypertension, congestive heart failure, rheumatoid arthritis, osteoporosis, and a history of fracture. Compared with PS-matched entecavir-treated patients, the risk of incident fracture in TDF-treated patients was comparable in the first 24 months (weighted subdistribution hazard ratio [wSHR] 0.98, 95%CI 0.56-1.72, p=0.946) but increased after month 24 (wSHR 1.79, 95%CI 1.11-2.89, p=0.017). The 24-, 60-, and 96-month cumulative incidence (95%CI) of fracture in TDF-treated and entecavir-treated patients were 2.3% (1.6%-3.4%) versus 2.6% (1.9%-3.5%), 6.4% (5.0%-8.2%) versus 4.7% (3.8%-6.0%), and 10.2% (8.3%-12.6%) versus 6.8% (5.4%-8.5%) respectively (Figure).

Conclusions: Fracture risk increased with TDF treatment for ≥24 months in elderly patients with CHB. Selection of nucleos(t)ide analogues should be individualised based on age and comorbidities.

Abstract Submission No. 100228

Lipid safety of tenofovir alafenamide during 96-week treatment in e

Wenjuan Zhao1, Yi Liu1, Mengdi Zhang3, Zixin Cui1, Zhan Qu4, Viyang Li1, Meijuan Wan1, Wen Wang1, Gong Feng3, Yunru Chen1, Shumei Lin1, Feng Ye1

1The First Affiliated Hospital of Xian Jiaotong University Xi’an China, 2School of Nursing, Xi’an Jiaotong University Health Science Center Xi’an China, 3Xi’an Medical University Xi’an China

Background: TAF was the first-line antiviral drug recommended by major clinical guidelines for the treatment of HBV infection. Antiviral
therapy requires long-term treatment, so long-term efficacy and safety of the drug are very important. This study was aimed at investigating the dynamics of lipid profile in naive CHB patients for 96 weeks.

**Methods:** Naive CHB patients treated with TAF were enrolled in this study. Consecutive NA-treated CHB-DM patients were recruited from 2017 to 2021 and then obtained their 1-year follow-up data to establish a predict model of 1-year HBVDNA clearance.

**Results:** 137 CHB patients treated with TAF were enrolled. Mean Age was 40.71±10.41 years, 62.04% were male. During 96 weeks of TAF treatment, TC and LDL-c levels gradually increased during treatment with TAF until 24 W (TC: 168.56 vs 170.87 mg/dL; LDL-c: 46.16 vs 47.16 mg/dL; P > 0.05), and then decreased and showed no statistical difference at 96 weeks (TC: 155.41 mg/dL; LDL-c: 43.3 mg/dL; P > 0.05) compared with baseline level. LDL-c levels did not change significantly during 96 weeks of treatment with TAF (105.16 vs 99.36 mg/dL, P > 0.05). TG levels gradually increased from 87.71 mg/dL to 116.1 mg/dL at 48 W (P = 0.009), and then decreased to 88.6 mg/dL at 96 weeks and showed no significant change compared with baseline (P > 0.05). TC/LDL ratio increased from 3.56 at baseline to 3.89 at 96 W, but there was still no statistical difference (P=0.05).

**Conclusion:** TAF treatment had a low effect on the lipid profile of Naive CHB patients over the course of 96 weeks.

**High normal ALT is an indicator for better response to antiviral therapy in chronic hepatitis B**

Mingqin Lu1, Wenxuan Shang1, Ruoyun Wang1, Chao Cai1, Yijing Cai1, Lu Chen1, Ruicong Chen1, Yuqun Wang1

1The First Affiliated Hospital of Wenzhou Medical University Wenzhou China

**Background:** Evidence showed patients with a normal ALT (40U/L as threshold) still have histological disease and there is still a lack of research on the prediction of antiviral benefits in these patients. The study aimed to investigate liver histologic disease in CHB patients with normal ALT, as well as to evaluate the potential benefits of antiviral therapy for these patients.

**Methods:** We retrospectively examined 1352 patients who underwent liver biopsy from 2017 to 2021 and then obtained their 1-year follow-up data to establish a predict model of 1-year HBVDNA clearance.

**Results:** ALT levels were categorized into high and low, with thresholds set at ≥30 for males and ≥16 for females through Youden’s Index. In the high normal ALT group, more patients have significant histological disease (56.43% vs 43.82%, p < 0.001). The threshold of high normal ALT in our study has similar discriminative ability with the threshold of the AASLD 2016 (male ≥30, female ≥19). Multivariate logistic analysis showed that high normal ALT, defined by two different thresholds, were both identified as an independent predictor of 1-year HBVDNA clearance after antiviral treatment (OR 1.993, 95% CI 1.115-3.560, p=0.020; OR 2.000, 95% CI 1.055-3.793, p=0.034, Table 4). Both of the models had higher AUC compared with the current scoring system, and there was no obvious difference between two models (AUC:0.8840 vs 0.8835).

**Conclusions:** Male ≥30, female ≥19 or ≥16 are suggested to be better thresholds for normal ALT. CHB patients with high normal ALT have a potentially better benefit from antiviral therapy.

**CHB patients receiving NAs therapy and achieving HBsAg loss can safely discontinue medication**

En-Qiang Chen1, Yu-Jing Li1, Cheng-Run Song1, Lan-Qing Li1, Jing Zhou1, Meng-Lan Wang1, Ya-Chao Tao1, Dong-Bo Wu2, Wei Jiang1, Yong-Hong Wang1, Hong Tang1

1Center of Infectious Diseases, West China Hospital, Sichuan University Chengdu China

**Objective:** This study aims to investigate the HBsAg negative maintenance rate and possible predictive factors after discontinuation in non-cirrhotic CHB patients with serum HBsAg negative conversion after long-term nucleos(t)ide analogues (NAs) treatment.

**Method:** This is a single-center retrospective study targeting CHB patients who received NAs treatment and achieved negative HBsAg conversion in non-cirrhotic patients. These patients were all treated and followed up at the Hepatitis Clinic of West China Hospital of Sichuan University. The CHB patients finally included in the analysis must have complete demographic and clinical data, and all discontinued patients underwent serum HBVRNA and HBeAg testing at the time of discontinuation.

**Result:** A total of 137 non-cirrhotic CHB patients with negative serum HBsAg were screened, 83 patients refused to discontinue the medication, and only 54 patients agreed to discontinue the medication. Among these 54 patients who agreed to discontinue medication, there were 43
Longitudinal Changes in Renal Function in Patients with Chronic Hepatitis B on Antiviral Treatment

Jongji Choi1, Hyeeyeon Hong1, Minjoo Cho1, Chaeyeon Lim1, Won-Mook Choi2, Danbi Lee3, Ju Hyun Shim1, Kang Mo Kim3, Young-Suk Lim1, Han Cho Lee1

1Asan Medical Center, University of Ulsan College of Medicine
Seoul South Korea

Background & Aims: Patients with chronic hepatitis B (CHB) on nucleos(t)ide analogues (NUCs) often experience renal function decline. Conflicting results regarding the impact of NUC use and renal function have recently been reported. We aimed to examine longitudinal changes in renal function according to the NUC treatment type compared with untreated patients.

Methods: From 2014 to 2022, 10,642 patients with CHB were retrospectively analyzed. The primary outcome was chronic kidney disease (CKD) progression, which was defined as a minimum one-stage elevation. Propensity score (PS) matching was employed for outcome comparisons.

Results: In the PS-matched cohort of 1,996 pairs, the NUC-treated group (7.6/100 person-years [PYs]) had a significantly higher CKD progression risk than the untreated group (4.4/100 PYs), with a hazard ratio (HR) of 1.70 (P<0.001). The tenofovir alafenamide (TAF)-treated group (7.9/100 PYs) showed a 1.76-fold increased CKD progression risk compared with the untreated group (4.5/100 PYs) in the PS-matched cohort (P<0.001). Both the entecavir (ETV)- and tenofovir alafenamide (TAF)-treated groups showed CKD progression risks comparable to those of the untreated group in the PS-matched cohorts of 755 and 426 pairs, respectively (P=0.132 and P=0.120, respectively). No significant CKD progression risk was found between the ETV- (6.0/100 PYs) and TAF-treated (5.2/100PYs) groups in the PS-matched cohort of 510 pairs (P=0.118).

Conclusions: NUC-treated patients, especially those on TDF, faced a higher CKD progression risk than untreated patients. ETV- and TAF-treated patients presented comparable CKD progression risks to untreated patients. No difference was observed between ETV and TAF in the risk of CKD progression.

Effects of ETV and TDF on the incidence and severity of COVID-19 in chronic hepatitis B patients

Xingmei Liao1, Yujie Fan1, Chunxuan Zhong1, Siru Zhao1, Liangxu Guo1, Wenyuan Tan1, Junhua Yin1, Yuan Li1, Rong Fan1

1Guangdong Provincial Key Laboratory of Viral Hepatitis Research, Guangdong Provincial Clinical Research Center for Viral Hepatitis, Department of Infectious Diseases, Nanfang Hospital, Southern Medical University, Guangzhou, China Guangzhou China

Background: Whether different anti-hepatitis B virus (HBV) drugs have different effects on COVID-19 is controversial. We aimed to evaluate the incidence of COVID-19 in chronic hepatitis B (CHB) patients receiving anti-HBV treatment, and to compare the impact of entecavir (ETV) and tenofovir disoproxil fumarate (TDF) on the severity of COVID-19.

Methods: CHB outpatients were enrolled from December 2022 to February 2023. Questionnaires were used to collect whether subjects had COVID-19 within the past 2 months, and the information of symptoms, duration, and severity if infected.

Results: 630 CHB patients were enrolled, 64.3% (405/630) patients had COVID-19. No COVID-19 patient required hospitalization,
intensive care unit admission, oxygen support or died. Majority of patients reported mild (32.8% [133/405]) and moderate (48.1% [195/405]) symptoms. After propensity score matching, 400 matched patients were obtained (ETV: 238; TDF: 162), among which the incidences of COVID-19 were comparable between ETV and TDF-treated patients (60.1% [143/238] vs. 64.2% [104/162], p=0.468). The proportion of patients complicated with any symptom caused by COVID-19 were also similar (ETV vs. TDF: 90.9% [130/143] vs. 91.3% [95/104], p=1.000). In addition, the severity of overall symptom was comparable between ETV and TDF-treated patients, in terms of proportion of patients complicated with severe symptom (9.8% vs. 8.7%, p=0.989), symptom duration (4.3 vs. 4.3 days, p=0.927), and symptom severity score (4.1 vs. 4.0, p=0.758). Subgroup analysis supported these results.

**Conclusions:** During the current pandemic, the vast majority of CHB patients experienced non-severe COVID-19, and ETV and TDF did not affect COVID-19 severity differently.

---

**Soluble PD-1 and BTLA proteins as biomarkers for predicting the anti-HBV treatment responsiveness**

**Hoang Hai1, Masaru Enomoto1, Le Thi Thanh Thuy1, Naoshi Odagiri1, Kohei Kotani1, Hiroyuki Motoyama1, Ritsuzo Kozuka1, Atsushi Hagihara1, Etsushi Kawamura1, Hideki Fujii1, Sawako Uchida-Kobayashi1, Norifumi Kawada1**

1Osaka Metropolitan University Graduate School of Medicine Osaka Japan

**Aim:** This study aimed to evaluate the levels of soluble immune checkpoint proteins and their changes in patients with chronic hepatitis B during treatment with nucleos(t)ide analogues (NUCs) or pegylated interferon-α (PegIFNα) and to identify potential biomarkers for predicting treatment responsiveness.

**Methods:** This study included 32 patients with chronic hepatitis B: 20 patients received NUC (entecavir or tenofovir) in an infinite course ≥48 weeks, and 12 patients received PegIFNα monotherapy in a 48-week finite course. The concentrations of 16 soluble checkpoint proteins were measured using multiplexed fluorescent bead-based immunoassays in sera collected at baseline, 12 weeks, and 48 weeks of treatment.

**Results:** NUC treatment resulted in significant decreases in 10 of the 16 soluble (s) immune checkpoint proteins, most of which were important inhibitory factors including sPD-1, sCTLA-4, sTIM-3 and sCD40. In contrast, during PegIFNα treatment, two inhibitors, sTIM-3 and sLAG-3, increased, while the stimulatory factors sGITRL and sCD40 decreased. Treatment response, defined as a 0.5 log decrease in hepatitis B surface antigen (HBsAg) levels, was obtained in 6 of the 20 patients (30%) in the NUC group and in 5 of the 12 patients (42%) in the PegIFNα group. The fold changes of sCTLA and sPD-1 in responders by week 12 of PegIFNα treatment were significantly lower than those of the non-responders (P=0.028 and 0.042, respectively).

**Conclusions:** We found different changes in soluble immune checkpoint proteins between NUC-treated and PegIFNα-treated patients. Circulating soluble PD-1 and BTLA proteins are potential biomarkers for prediction of PegIFNα responsiveness.

**TAF and TDF for Chinese Assisted Reproductive Pregnant Women with HBV Infected: A Prospective Study**

**Liyuan Zhang1, Fangxiang Fu1, Yuyan Wang1, Kunliang Wu1, Qiang Wang2, Yuting Zhu1, Xiaojing Zheng1, Dongyao Cai1, Yazhuan Yu1, Min Wu1, Sifu Liu1, Qing Xue1, Juan Li1, Yongguo Du1**

1The Second Affiliated Hospital of Hainan Medical University Haikou China

**Background:** Aim to evaluate effective and safe of Tenofovir alafenamide fumarate (TAF) and Tenofovir disoproxil fumarate (TDF) in preventing mother-to-child transmission (pMTCT) of HBV for pregnant women with assisted reproduction.

**Methods:** Prospective study, from January 2020 to January 2022, pregnant women with HBsAg (+) and HBV DNA (+) who had normal ALT in assisted reproduction at the Second Affiliated Hospital of Hainan Medical College were enrolled. The mothers received TAF 25mg or TDF 300mg daily from gestational week 24 until 2 weeks postpartum. All infants received active immunization combined with passive immunization after birth and were followed up to 7 months after delivery. The primary outcome was the hepatitis B surface antigen (HBsAg)-positive rate at 7 months for infants. The secondary outcome was the safety of mothers and infants.

**Results:** Totally 67 pregnant women were enrolled, including 21 in the TAF group and 46 in the TDF group. The two groups are comparable in their baseline. At 7 months, the HBsAg positive rate of infants was 0% for both groups. During the follow-up period, neither group of pregnant women experienced any adverse reactions resulting in discontinuation or change of medication; Both groups of pregnant women had no birth defects in their babies, and their physical development were normal at birth.

**Conclusion:** It is safe and effective to administer TAF and TDF in HBV pMTCT for pregnancy women with assist reproduction and their infants, no significant difference between two groups.

**Humoral responses after COVID-19 vaccination and breakthrough infection in CHB patients**

**Guanhua Zha1, Zhiwei Chen1, Na Wu1, Tianquan Huang1, Zhiling Deng1, Dachuan Cai2, Mingli Peng1, Peng Hu1, Hong Ren1**

1Department of Infectious Diseases, the Second Affiliated Hospital of Chongqing Medical University, Chongqing, China Chongqing China

**Background:** The clinical and immunological features after COVID-19 vaccination and breakthrough infection (BTI) during Omicron wave in CHB patients were still unclear.

**Methods:** In this study, 101 patients with CHB were recruited from the Second Affiliated Hospital of Chongqing Medical University during the Omicron wave epidemic. Clinical data were collected by questionnaire survey and electronic medical record. Blood samples were used to determine the antibody responses, B and T cell responses.

**Results:** The most common symptoms of COVID-19 infection in CHB were upper respiratory symptoms, with 5 days median duration, and all of them were mild or moderate. CHB patients were more susceptible to develop symptoms of COVID-19 infection and presented with more severe symptoms than healthy controls. The liver function was not significantly damaged and HBV-DNA was not significantly increased after COVID-19 infection. CHB patients could establish a stronger immune barrier after BTI than every period after vaccination. The type of vaccine administered was the main factor affecting antibody response after BTI. Patients with CHB received the recombinant SARS-CoV-2 protein vaccine (ZF2001) generated a more robust
immune barrier after BTI than those received the inactivated vaccine. It is worth noting that B cell immune response against the wild strain was higher than the Omicron strain after Omicron BTI. CHB patients post BTI developed a similar antibody response compared with healthy controls, but weakened B cells response.

**Conclusions:** CHB patients followed favorable outcome post COVID-19 infection, in turn, COVID-19 infection will not result in CHB exacerbation. The immune responses were robust after BTI in CHB patients.

---

**Comparing M2BPGi, APRI and FIB4 for Liver Fibrosis Diagnosis with Pathology in Chronic Hepatitis B**

Ya-Wei Hsu1, Cheng-Yuan Peng2, Ming-Lun Yeh3, Jia-Horng Kao4, Tai-Chung Tseng4

1E-Da Hospital, I-Shou University Kaohsiung Taiwan, 2China Medical University Hospital Taichung Taiwan, 3Kaohsiung Medical University Hospital Kaohsiung Taiwan, 4National Taiwan University Hospital Taipei Taiwan

**Background:** Serum Mac-2 Binding Protein Glycosylation Isoform (M2BPGi) levels correlate with liver fibrosis severity, but large-scale studies with histopathological confirmation are scarce in patients with chronic hepatitis B (CHB).

**Methods:** We retrospectively enrolled treatment-naive CHB patients with liver biopsies from four hospitals in Taiwan, excluding those with hepatitis C virus or human immunodeficiency virus co-infection, or with malignancy. Serum M2BPGi, APRI, and FIB-4 levels were quantified at liver biopsy. Their performance for the diagnosis of fibrosis stage, which was evaluated by the META VIR system, was assessed by the receiver operating characteristic (ROC) curves. Optimal cutoffs were determined for F2 or above, F3 or above, and cirrhosis. Subgroup analyses were performed.

**Results:** Among 670 eligible patients (median age: 45; 73.3% male), fibrosis stages were F0-1 (33.9%), F2 (22.4%), F3 (18.2%), and F4 (23.6%). The stage fell between F3 and F4 in 13 patients (1.9%). Mean and median M2BPGi levels rose significantly (P<0.001) across fibrosis stages. M2BPGi demonstrated superior performance (area under the ROC) in diagnosing F2 or above (0.71), F3 or above (0.71), and F4 (0.72) compared to APRI (F2+: 0.58, F3+: 0.56, F4: 0.55; P<0.001) and comparable performance to FIB-4 (F2+: 0.70, F3+: 0.70, F4: 0.69; P=0.1). In patients with ALT flares (ALT >5x normal limit), M2BPGi was significantly better than FIB4 in identifying cirrhosis (0.82 vs. 0.67; P=0.015). Optimal M2BPGi cutoffs were 1.03 for F2+ (sensitivity 71.6%, specificity 63.4%) and 1.20 for F3+ (sensitivity 70.0%, specificity 62.1%). Results remained consistent across subgroups.

**Conclusions:** M2BPGi significantly outperforms APRI in diagnosing fibrosis in CHB patients. As compared to FIB4, M2BPGi is comparable overall but more accurate in patients with ALT flares.

**Deep Sequencing of the HBV Genome in Taiwan: Risk of HCC from Primary and Secondary Genotypes**

Ding-Lian Wang1,2, Chih-Jen Huang1, Mei-Hung Pan2, Hwai-I Yang1

1Graduate Institute of Life Sciences, National Defense Medical Center Taipei Taiwan, 2Genomics Research Center, Academia Sinica Taipei Taiwan

**Background:** Several studies have demonstrated that the Hepatitis B virus (HBV) is a diverse DNA virus comprising 10 genotypes (A-J). Genotypes B and C are predominant in Asia, and patients can be co-infected with multiple HBV genotypes. While previous studies predominantly focused on primary genotypes, the impact of secondary genotypes on HCC has been largely overlooked. We investigated the impact of various HBV genotype combinations on the risk of HCC.

**Methods:** This study utilizes a longitudinal cohort of HBV chronic carriers (REVEAL-HBV) collected from 7 communities in Taiwan. PacBio sequencing technology was employed to deeply sequence HBV DNA from patients’ serum. The proportions of primary and secondary genotypes of each patient were then identified. Subsequently, we analyzed the association between HCC and different genotype combinations.

**Results:** Our finding revealed that the HBV C2 subgenotype presented a higher risk of HCC (OR=4.73, 95%CI=2.85 - 7.85), aligning with previous studies (Table 1). To elucidate the impact of diverse HBV genotype combinations on HCC, we performed a detailed grouping analysis of primary and secondary subgenotypes. The results indicated...
that among the groups with mixed C genotype infections, C+B and C+C, were the main combinations predominantly responsible for the elevated risk of HCC (C2+B2: OR=6.6, 95% CI=1.7-26.0, C2+C1: OR=11.9, 95% CI=3.1-45.4, C2+C6: OR=7.0, 95% CI=1.9-26.1, C2+C8: OR=12.4, 95% CI=2.5-62.2, C2+C10: OR=8.4, 95% CI=2.4-29.7) (Table 2).

Conclusion: Our data indicates that groups co-infected with multiple HBV genotypes possess a higher risk of developing HCC compared to those with a singular infection.

Evolution of HBV genomic structures without selective pressure of antiviral treatment

Soichi Arasawa1, Haruhiko Takeda2, Atsushi Takaï2, Hiroshi Seno2

1Infection Control Team, Kyoto University Hospital Kyoto Japan, 2Department of Gastroenterology and Hepatology, Kyoto University Hospital Kyoto Japan

Background: Hepatitis B virus (HBV) causes persistent infection to human bodies and develops genomic structural variants. However, the characteristics of these structural variants, such as localization in HBV genome, length, and long-term survivability during untreated persistent infection are not fully known.

Methods: Twenty-five sera were collected from 10 cases of treatment-naïve chronic HBV infection. HBV-DNA was extracted from these sera and was sequenced using PacBio® third generation sequencer. The sequence errors were corrected using circular consensus sequencing.

Results: The nucleotide sequences of approximately 800-thousand copies of HBV genome were determined. Totally, 431 types of genomic structural variants were detected including 407 deletions, 22 insertions, and 2 duplications. The number of structural variants at the active hepatitis phase negative for anti-HBe were significantly larger than that at the anti-HBe-positive inactive hepatitis phase. Major structural variants with high allele frequencies in each case were in-frame deletions that cause nine to 91 amino acid deletions in PreS or C protein.

Phylogenetic analysis indicated that these major structural variants can survive years and accumulate nucleotide substitutions independently from non-structural-variants during treatment-free persistent infection.

Conclusions: During persistent infection, genomic structural variants of HBV form quasispecies in the host bodies and each variant evolves independently for several years or longer.

Assessing liver cirrhosis progression under the Baveno VII definition using hidden Markov model

Vicki Wing-Ki Hui1, Dongrong Li2, Yee-Kit Tse1, Terry Cheuk-Fung Yip3, Vincent Wai-Sun Wong1, XiaoDan Fan1, Grace Lai-Hung Wong1

1Department of Medicine and Therapeutics, Medical Data Analytics Centre (MDAC), Institute of Digestive Disease Hong Kong Hong Kong, 2Department of Statistics Hong kong Hong Kong

Background: The Baveno VII consensus highlighted post-decompensation hepatic recompensation. However, ambiguities in its definition might lead to data inaccuracies. Our study identified predictors for cirrhosis progression and regression, accounting for misdiagnoses.

Methods: A Bayesian inhomogeneous hidden Markov model was developed among patients with chronic hepatitis B (CHB)-related cirrhosis in Hong Kong to determine transition probabilities among liver cirrhosis states and variables.

Results: We evaluated 5,263 CHB-related cirrhosis patients. Initially, 4,690 (89%) were compensated, and 573 (11%) were decompensated.
Results: At a mean follow-up of 32 ± 47 months, 2,317 (44%) remained compensated, 158 (3%) remained decompensated, 1,341 (25%) experienced non-liver deaths. Older age is associated with a higher likelihood of progressing to decompensated cirrhosis (odds ratio [OR]=2.41). Females are less likely to progress or deteriorate from a compensated state (OR ranges from 0.008 to 0.061). However, they have a higher likelihood of transitioning to decompensated cirrhosis (OR≈8.50). The presence of hepatocellular carcinoma increases the likelihood of transitioning to decompensated cirrhosis and reduces the chances of progressing to recompensated cirrhosis.

Conclusions: Age, gender, and hepatocellular carcinoma were key determinants in disease transitions. Using the model’s outcomes, we can deduce the importance of covariates across multiple transitions and estimate the future disease trajectory for each patient.

Dynamic liver volume changes predict re-compensation of HBV-related decompensated cirrhosis
Qijuan Zang1, Siyi Liu1, Juan Li1, Chengbin Zhu1, Qiao Zhang1, Yushan Liu1, Xiaonian Wu1, Yamin Wang2, Qiannan Wang1, Pan Huang1, Li Zhu3, Yingren Zhao0, Yingli He2
1Department of Infectious Diseases, the First Affiliated Hospital of Xi’an Jiaotong University, Xi’an, Shaanxi, China. Xi’an, Shaanxi, China. Xi’an China, 2Institution of Hepatology, The First Affiliated Hospital of Xi’an Jiaotong University, Xi’an, Shaanxi, China. Xi’an China, 3Shaanxi Clinical Research Center for Infectious Diseases, Xi’an, Shaanxi, China. Xi’an China.

Background: NUCs treatment may change or even reverse the progression of HBV-related decompensated cirrhosis, that is, the realization of re-compensation. The change of liver volume can reflect the function and regeneration ability of liver. Nevertheless, the precise clinical implications of dynamic liver volume changes among patients with re-compensation remain uncertain.

Methods: This retrospective study involved the administration of NUCs treatment for a minimum of 48 weeks and a follow-up period of at least 2 years to all patients diagnosed with HBV-related decompensated cirrhosis. Two abdominal computed tomography (CT) scans were conducted at baseline and during the first two years of follow-up to measure the liver volume (LV1, LV2). The change in liver volume (ΔLV = LV2-LV1) was then calculated. Re-compensation was defined as the disappearance of decomposition complications and stability for a minimum of one year.

Results: A total of 159 patients were included, 38% of the patients achieved re-compensation, and the liver volume of the recompensated patients was significantly larger than that of the decompensated patients (1072.8 cm3 vs 848.11 cm3, P < 0.001). Logistic regression analysis screened the independent predictive factors for predicting re-compensation of HBV-related decompensated cirrhosis as ΔLV, Hb, Na and Female, respectively, and established a prognostic model based on dynamic liver volume. The model demonstrated good performance in predicting re-compensation (C index 0.951, AUC value 0.959).

Conclusion: Effective antiviral therapy can reverse the liver volume of HBV-related decompensated cirrhosis. The model based on dynamic liver volume change is a reliable model for predicting re-compensation.

Investigation on current situation and trend of antiviral treatment for chronic hepatitis B in China
Min-ran Li1, Liu Yang1, Jin-zhong Li2, Calvin Q. Pan3, Er-hei Dai2
1Division of Infectious Disease, the First Affiliated Hospital, Jinan University, Guangzhou, 510632, R.P. China. Guangzhou, China. Guangzhou China, 2Division of Liver Disease, The Fifth Hospital of Shijiazhuang, Hebei Medical University, Shijiazhuang, China. Shijiazhuang, China, 3Division of Gastroenterology and Hepatology, Department of Medicine, NYU Langone Health, New York University School of Medicine, New York, NY New York American

Objective: To investigate the current situation and trend of antiviral therapy in patients with chronic hepatitis B (CHB) in China, and to analyze the factors affecting patients’ acceptance of antiviral therapy and the choice of treatment methods.

Method: An electronic questionnaire was used to investigate patients with CHB in 12 hospitals including the First Affiliated Hospital of Jinan University and the Fifth Hospital of Shijiazhuang City in 2023. The contents included demographic characteristics, follow-up compliance, treatment compliance, knowledge of antiviral drugs and other influencing factors were analyzed by binary logistic regression.

Results: A total of 1360 patients with CHB were included in the questionnaire, of which 77.4% received antiviral therapy and 32.6% did not. Regression analysis showed that whether patients received antiviral treatment was related to education level, course of hepatitis B, HBV DNA results, follow-up compliance, treatment compliance, acceptance of antiviral treatment indications, understanding of antiviral drugs and price of long-acting interferon (P < 0.05). There were 399 patients over 30 years old with positive HBV DNA test, of whom only 30.6% received antiviral treatment. Regression analysis showed that whether the patients received antiviral treatment was related to their education level, follow-up compliance, treatment compliance, acceptance of antiviral treatment indications and understanding of nucleoside (acid) analogues (P < 0.05). Among 1052 patients who received antiviral therapy, 88.7% were oral nucleoside (acid) analogues, 11.3% were long-acting interferon monotherapies or combinations. And 913 patients (69.4%) had strong intention to pursue the clinical cure of CHB, but only 13.2% of them chose long-acting interferon. Regression analysis showed that the influencing factors of whether patients chose long-acting interferon were related to the understanding of long-acting interferon for clinical cure of CHB, the fear of HBV DNA results in liver cirrhosis or cancer, the understanding of nucleoside (acid) analogues and the treatment compliance (P < 0.05).

Conclusion: Whether patients with CHB choose antiviral therapy at present is influenced by many factors, such as educational level, compliance, understanding of diseases and drugs, etc. Doctors should strengthen the propaganda of clinical cure of hepatitis B and long-acting interferon treatment to improve the treatment rate and effective rate of CHB, which is beneficial to the early elimination of hepatitis B in China.

Exploratory biomarkers HBcAg and HBV RNA: relationship with bepirovirsen response in B-Clear
Yasuhito Tanaka1, Jerome Bouquer2, Scott D. Speer3, Robert Elston4, Phillip Yates4, Jennifer Cremer5, Geoff Quinn4, Melanie Paff3, Dickens Theodore5

1Department of Gastroenterology, New York University School of Medicine, New York, NY, New York American, 2Division of Liver Disease, The Fifth Hospital of Shijiazhuang, Hebei Medical University, Shijiazhuang, China, 3Division of Gastroenterology and Hepatology, Department of Medicine, NYU Langone Health, New York University School of Medicine, New York, NY, New York American, 4Department of Medicine, New York University School of Medicine, New York, NY, New York American, 5Division of Infectious Diseases, the First Affiliated Hospital, Jinan University, Guangzhou, 510632, R.P. China, Guangzhou, China.
Background: Bypirovirsen (BPV) is an antisense oligonucleotide targeting HBV RNAs. B-Clear is a Phase 2b study (NCT04449029) assessing the efficacy and safety of BPV in participants (pts) with chronic hepatitis B. This post-hoc analysis looked at the presence and levels of hepatitis B core-related antigen (HBcrAg) and HBV RNA and their relationship with response to treatment.

Methods: B-Clear study pts were either receiving concomitant stable nucleos(t)ide analog therapy (On-NA) or not receiving NA (Not-on-NA). Pts were randomized (3:3:3:1) into 4 treatment arms receiving up to BPV 300mg weekly for up to 24wks with loading doses in Arm 1-3. HBcrAg and HBV RNA were assessed with Lumipulse G HBcrAg (Fujirebio) and custom RT-qPCR, respectively.

Results: HBV RNA was target not detected (TND) at baseline in 41.2% (93/228) Not-on-NA and 75.2% (170/226) On-NA pts. Mean HBcrAg and HBV RNA decreased from baseline to end of treatment (EOT) across both populations and all treatment arms (Table). Mean baseline HBcrAg and HBV RNA were lower in pts with sustained HBsAg loss (<0.05 IU/mL for 24wks post BPV treatment) compared with non-responders, respectively, but were not significant predictors of response.

Conclusions: HBV RNA was more likely to be TND at baseline in On-NA than Not-on-NA pts. Average EOT reductions were larger in Not-on-NA than On-NA pts. HBcrAg and HBV RNA at baseline were lower but not significantly associated with sustained HBsAg seroclearance. HBcrAg and HBV RNA may be worth exploring as early indicators of treatment response, primarily in patients not virally suppressed.

Background: In CHB-related cirrhosis patients on long-term antiviral therapy, hepatocellular carcinoma (HCC) risk persists, motivating the need for risk stratification. The GAAD score, encompassing gender, age, alpha-fetoprotein, and des-gamma carboxyprothrombin (DCP) measurements, is designed for early-stage HCC detection. This study investigates the predictive role of the GAAD score in HCC development in CHB-related cirrhosis patients on antiviral therapy.

Methods: We conducted a retrospective cohort study to include HBV-related cirrhosis patients undergoing long-term antiviral therapy with regular HCC surveillance. The on-treatment plasma samples were retrieved for alpha-fetoprotein and DCP measurements by the Roche Elecsys® system to calculate the GAAD score. Cox proportional hazard regression analysis identified risk predictors for HCC.

Results: A total of 499 patients were included and categorized into “prior HCC” (n=47), “HCC” (n=56), and “no HCC” (n=396) groups with a median GAAD score of 1.12, 0.84, and 0.54, respectively (p<0.001). Among the 452 patients without prior HCC, their median age was 60, and they received a median of 6.2 years of antiviral therapy. After a median of 3.3 years of follow-up, 56 patients developed HCC. A GAAD score of 0.71 and 1.64 significantly stratified the risk of HCC (log-rank P<0.001). After adjusting for age, sex, and FIB-4 index, a GAAD score ≥4.64 and GAAD score 0.71-1.64 significantly increased the risks of HCC by 8.68-fold (95% CI: 3.50-21.55) and 2.25-fold (95%CI: 0.96-5.25) respectively, compared with a GAAD score of <0.71.

Conclusions: After 6 years of antiviral therapy, a high GAAD score significantly stratified the risks of HCC development, and high-risk patients should receive intensive HCC surveillance.

Abstract

Background: Hepatitis B surface antigen (HBsAg) loss is the optimal outcome for patients with chronic hepatitis B (CHB) but rarely occurs...
with currently approved therapies. We aimed to develop and validate a prognostic model for HBsAg loss on treatment using longitudinal data from a large, prospectively followed, nationwide cohort.

**Methods:** CHB patients on treatment were enrolled from 50 centers in China. Quantitative HBsAg (qHBsAg) were prospectively evaluated biannually per protocol. Longitudinal Discriminant Analysis algorithm was used to estimate the incidence of HBsAg loss.

**Results:** In total, 9437 CHB patients who had initiated antiviral treatment 55·2 (IQR:12·1-100) months prior to enrollment and had qHBsAg 2·8 (IQR:2·3-3·5) log10IU/mL at entry were analyzed. With a median follow-up of 65·5 (IQR:50·5-84·7) months, the 5-year cumulative incidence of HBsAg loss was 3·0%. A prediction model integrating all longitudinal information of each patient during follow-up, designated GOLDEN model, was developed and validated. The AUCs of GOLDEN model were 0·978 (95%CI:0·972-0·984) and 0·977 (95%CI:0·973-0·981) in the training and external validation sets, respectively, and were significantly better than those of a single qHBsAg measurement. GOLDEN model identified 10·5-11·8% of patients with a high probability of HBsAg loss (5-year cumulative incidence: 19·3-31·1%), and excluded 88·2-89·5% of patients with zero incidence. Moreover, GOLDEN model consistently performed excellently among various subgroups.

**Conclusions:** This novel GOLDEN model, based on longitudinal information, accurately predicts HBsAg clearance, provides a reliable estimate of functional HBV cure and is valuable to identify favorable patients for benefiting from novel anti-HBV therapies.

**Efficacy of combination treatment of TLR7 agonist and anti-PD-L1 in virally suppressed CHB patients**

Qin NING1, Ting Wu1, Di Wu1, Yuyin Chen1, Da Huang1, Zhize Yuan1, Zhongnan Xu2, Shuna Wang2, Dandan Huo2, Weiming Yan1, Meifang Hau1

1Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology Wuhan China, 2Chia Tai Tianqiang Pharmaceutical Group Co., Ltd Nanjing China

**Background:** TQB2450, a PD-L1 antibody, inhibits PD-1/PD-L1 axis and rouses adaptive immune response to HBV. This study aimed to evaluate the safety and efficacy of nucleos(t)ide analog (NA) and TQA3334 combined with/without TQB2450 in CHB patients (pts).

**Method:** Totally 24 viral-suppressed (250 ≤IU/ml HBsAg ≤ 5000 IU/ml, HBV DNA < 20 IU/ml) CHB pts (HBsAg-positive; HBsAg-negative=1:2) were randomized to receive NA (monotherapy, n=6), NA+TQA3334 (dual therapy, n=9) or NA+TQA3334+ TQB2450 (triple therapy, n=9). TQA3334 (1.2mg or 1.5mg, QW) and TQB2450 (400mg, Q3W) were administrated for 24 weeks, and NA was given throughout this 48-week study. The HBsAg (Roche) reduction was evaluated.

**Results:** One participant received dual therapy withdrew at week 6. Adverse events (AEs) were more common in triple therapy, and the grade 1 thyroiditis was the most common immune-related AEs in pts received TQB2450. All the events were resolved before the end of follow-up (EOF). At the end of treatment (EOT), triple therapy was associated with greater HBsAg reduction compared to monotherapy and dual therapy (0.04 ± 0.08, 0.04 ± 0.16, and 0.37 ± 0.50 log10 IU/ml). In triple therapy group, 1.5mg TQA3334 administration had a greater HBsAg reduction (0.46 vs 0.32 log10 IU/ml) at EOT. HBsAg remained lower than those of EOT in 52.5% and 65.6% of pts received dual therapy and triple therapy respectively at EOF.

**Conclusion:** The combination of NA, TQA3334 and TQB2450 induced greater HBsAg decline in viral-suppressed CHB pts with good safety. Moreover, high dose of TQA3334 promoted HBsAg reduction in triple therapy.

**Risk factors for low level viremia in chronic hepatitis B patients receiving antiviral treatment**

Fehmi Tabak1, Imran Hasanoglu2, Rahmet Guner2, Esra Verikeya Zerdali2, Selma Tosun2, Yusuf Onlen2, Figen Yildirim3, Tuba Turunc3, Ozgur Guna4, Ayse Batirel910

1Istanbul University Cerrahpasa Medical Faculty Istanbul Turkey, 2Ankara City Hospital Ankara Turkey, 3Istanbul Haseki Training and Research Hospital Istanbul Turkey, 4Bozyaka Training and Research Hospital Izmir Turkey, 5Mustafa Kemal University Medical Faculty Hatay Turkey, 6Antalya Training and Research Hospital Antalya Turkey, 7Adana City Hospital Adana Turkey, 8Samsun Training and Research Hospital Samsun Turkey, 910Kartal Dr. Lutfu Kirdal City Hospital Istanbul Turkey

**Background:** Available antiviral agents have demonstrated the ability to suppress HBV DNA replication and reduce the risk of liver-related complications and some patients continue to experience low-level
viremia (LLV) which is defined as HBV DNA <2000 IU/ml. In this study, we aimed to evaluate the incidence and the factors that influence low-level LLV in patients with CHB receiving antiviral treatment.

**Methods:** This multicenter retrospective observational study included CHB patients who had received antiviral treatment and univariate and multivariate logistic regression analyses were conducted to investigate the risk factors for LLV.

**Results:** A total of 2455 patients from 32 centers included in the study. At the end of 1 year, incidence of LLV was 13.6%. To evaluate the risk factors for LLV, patients were divided into two groups as LLV and sustained virological response (SVR). Results of the univariate and multivariate logistic regression analyses are given in Table 1. Multivariate logistic regression analyses showed that patients with HBeAg positive serostatus, cirrhotic status, higher albumin levels and pretreatment HBV DNA levels > 1,000,000 IU/ml has increased risk for LLV. No significant difference was observed between patients receiving entecavir and tenofovir in terms of LLV.

**Conclusion:** Studies have demonstrated that a significant proportion of CHB patients, ranging from 20% to 40 maintain LLV. Results of this study emphasize that patients with HBeAg positive serostatus, cirrhotic status, higher albumin levels or pretreatment HBV DNA > 1,000,000 IU/ml has higher risk for LLV and should carefully monitored.

**Coffee consumption on advanced fibrosis and cirrhosis among hepatitis B patients: Meta-analysis**

Leah Anne E. Legaspi1, Arlinking K. Ong-Go1, Roberto N. De Guzman Jr.1

1Metropolitan Medical Center Manila Philippines

**Background:** Coffee consumption has preventive effect on liver fibrosis and cirrhosis among patients with hepatitis C and NASH. Existing evidence on its effect on hepatitis B are limited and contradicting.

**Methodology:** Literature search was done through PubMed, MEDLINE and google scholar. Four studies with total of 6413 hepatitis B patients were reviewed which correlated coffee consumption on advanced fibrosis and cirrhosis using risk ratio (RR). The cut-off for high coffee consumption was > 2 cups of coffee per day in three studies and consumption of coffee 4 to 7 days per week in one study.

**Results:** The summary estimate for any coffee consumption vs no consumption on cirrhosis was RR 0.96 (95% confidence interval [CI], 0.73-1.27). Summary estimate for advanced fibrosis for any coffee consumption vs no consumption was RR 0.69 (95% CI, 0.45-1.03). Comparison of low coffee consumption vs no consumption on cirrhosis showed RR 1.10 (95% CI, 0.82-1.49) and on advanced fibrosis showed RR 0.90 (95% CI, 0.53-1.54). In terms of high coffee consumption on cirrhosis RR 0.71 (95% CI, 0.48-1.05) while on advanced fibrosis was RR 0.62 (95% CI, 0.39-0.99). Results showed that the presumed effect of coffee consumption on prevention of liver fibrosis and cirrhosis was not observed in this study.

**Conclusion:** Among hepatitis B patients, coffee consumption has no effect on prevention of cirrhosis, whereas there is a trend towards advanced fibrosis among coffee drinkers. Limitations of this meta-analysis include varied cutoff values of outcome measurement, treatment status of HBV and level of ALT.

**Lower HBeAg level associates with higher spontaneous HBeAg seroclearance rate in CHB patient**

Hung-Yao Lin1, Chun-Jen Liu1,2,5, Tung-Hung Su1,2, Wan-Ting Yang2, Chun-Ming Hong3, Hung-Chih Yang1,5,6, Chen-Hua Liu6, Pei-Jer Chen1,5,6, Tai-Chung Tseng2,1, Horng Kao1

1Division of Gastroenterology, Department of Internal Medicine, National Taiwan University Hospital Taipei Taiwan, 2Hepatitis Research Center, National Taiwan University Hospital Taipei Taiwan, 3Hepatitis Research Center, National Taiwan University Hospital Taipei Taiwan, 4Division of Hospital Medicine, Department of Internal Medicine, National Taiwan University Hospital Taipei Taiwan, 5Graduate Institute of Clinical Medicine, National Taiwan University College of Medicine Taipei Taiwan, 6Department of Microbiology, National Taiwan University College of Medicine Taipei Taiwan

**Background and aims:** Hepatitis B e antigen (HBeAg) seroclearance is crucial in the management of chronic hepatitis B (CHB). This study aimed to elucidate the role of hepatitis B core-related antigen (HBcrAg) level, a biomarker for cccDNA, in predicting spontaneous HBeAg seroclearance in treatment-naive HBeAg-positive CHB patients.

**Methods:** This retrospective cohort study involved 484 treatment-naive HBeAg-positive CHB patients with extended follow-up at the National Taiwan University Hospital. The study explored the association of baseline and kinetics of HBcrAg levels with spontaneous HBeAg seroclearance rate over time.

**Results:** Of 484 patients, 331 experienced spontaneous HBeAg seroclearance during 3376.73 person-years of follow-up, with a mean seroclearance rate of 8.76% per year. Lower baseline HBcrAg level (log rank P < .001) was associated with a higher chance of HBeAg seroclearance by univariate analysis. By multivariate analysis, persistently low (HR: 2.43; 95% CI: 1.53-3.85) and decreasing to below (HR: 2.53; 95% CI: 1.97-4.65) 10^5 KU/mL at year 3 of follow-up were independent factors associated with spontaneous HBeAg seroclearance. In a subgroup analysis of 208 immune-tolerant patients, lower baseline HBcrAg level and a decline of HBcrAg were independently associated with higher rates of spontaneous HBeAg seroclearance.

**Conclusions:** HBcrAg-positive CHB patients maintaining HBcrAg levels below 10^5 KU/mL or achieving a decrease to below this threshold during follow-up are associated with a higher likelihood of clearing HBeAg spontaneously. These findings highlight the potential utility of HBcrAg as a prognostic marker in predicting the clinical course and directing management decision in HBeAg-positive CHB patients.

**Efficacy and safety of tenofovir alafenamide fumarate in chronic hepatitis B patients in real world**

Yuxuan Song1, Hui Ma1, Bo Feng1, Yandi Xie1

1Peking University People’s Hospital Beijing China

**Background:** Tenofovir alafenamide fumarate (TAF) has been treated in chronic hepatitis B (CHB) patients since 2018 in China. We aimed to assess the long-term efficacy and safety of TAF in a real-world setting.

**Methods:** Treatment-naive and treatment-experienced CHB patients who received TAF were included. Serum levels of hepatitis B virus (HBV) DNA, hepatitis B surface antigen (HBsAg) and hepatitis B e antigen (HBeAg) were analyzed at baseline, 24, 48, 72, 96, 120, 144, 168 and 192 weeks by immunoassays. Serum levels of alanine...
aminotransferase (ALT), triglyceride (TG), total cholesterol (TC) and low-density lipoprotein-cholesterol (LDL-C) were measured by biochemistry assay. Kidney function was measured by estimated glomerular filtration rate (eGFR) as per Cockcroft-Gault. Controlled attenuation parameter (CAP) and liver stiffness measurement (LSM) were analyzed by transient elastography.

**Results:** In total of 144 CHB Patients were followed up for 204 weeks. Fifty (34.72%) patients were treatment-naive (38% patients were HBeAg positive) and 94 (65.28%) patients switched from other NAs (47.87% patients were HBeAg positive). Among treatment-naive patients, the ALT normalization rate was 96% (48/50), the complete virological response (HBV DNA <20 IU/ml) rate was 76% (38/50) and the HBeAg seroconversion rate was 5.26% (1/19) at 48 weeks. The levels of HBV DNA and HBsAg were significantly decreased from the 5.27±1.29 log_{10} IU/ml at baseline to 1.32±0.27 log_{10} IU/ml and from 3.63±0.72 log_{10} IU/ml to 3.44±0.73 log_{10} IU/ml, respectively. LSM was significantly decreased from 13.1±8.01 kPa at baseline to 8.32±4.93 kPa at 48 weeks of treatment. No significant differences were observed in the levels of TG, TC, LDL-C, CAP and eGFR. Among treatment-experienced patients, decline of HBV DNA and HBsAg levels were also found. Most of patients had renal deterioration during TDF (76%) who were with eGFR <60 mL/min reversed to eGFR increase after 48 weeks of TAF treatment (P = 0.017). In patients with eGFR between 60 and 89 mL/min, the estimated eGFR decrease during TDF was halted after switching to TAF (P = 0.06).

**Conclusions:** TAF was effective and well-tolerated in present CHB cohort in real-world setting. Switching to TAF is conducive to the decline in HBV DNA and the improvement of kidney function.

A Model to Identify the Starting of Antiviral Therapy in Gray Zone Patients with Chronic Hepatitis B

Yu-Chen Fan1, Xue-Yan Yang1, Jing Zuo1, Xi-Dong Li2, Qiao Yang2, Yu-Bao Zheng3, Ming-Hua Zheng5, Yin-Ping Wu1, Ruo-Xi Ma3, Yu-Chen Fan1, Xue-Yan Yang1, Jing Zuo1, Xi-Dong Li2, Qiao Yang2, Yu-Bao Zheng3, Ming-Hua Zheng5, Yin-Ping Wu1, Ruo-Xi Ma3

1Department of Hepatology, Qilu Hospital of Shandong University Jinan China, 2Department of Infectious Diseases, Linyi People’s Hospital Linyi China, 3Department of Infectious Diseases, Sir Run Run Shaw Hospital, School of Medicine, Zhejiang University Hangzhou China, 4Department of Infectious Diseases, The Third Affiliated Hospital of Sun Yat-sen University Guangzhou China, 5MAFLD Research Center, Department of Hepatology, the First Affiliated Hospital of Wenzhou Medical University Wenzhou China, 6Department of Infectious Diseases, The affiliated Hospital of Qingdao University Qingdao China, 7State Key Laboratory for Diagnosis and Treatment of Infectious Diseases, National Clinical Research Center for Infectious Diseases, Collaborative Innovation Center for Diagnosis and Treatment of Infectious Diseases, The First Affiliated Hospital, College, 8Department of Infectious Diseases, The First Affiliated Hospital of Xi’an Jiaotong University Xi’an China

**Introduction:** Individuals who do not fit to any stage of natural history of chronic hepatitis B (CHB) are classified as gray zone; however, the management of these patients remains unclear. Here, we developed and validated a nomogram to predict the starting of antiviral therapy in gray zone patients.

**Methods:** We retrospectively collected 200 gray zone patients as no activity requiring antiviral treatment. Asymptomatic and incidentally detected chronic hepatitis B virus infected patients. The nomogram was tested by the area under receiver operating characteristic curve (AUROC), calibration plot and decision curve analysis.

**Results:** A total of 200 UAT patients were retracted and 78 patients(n=39%) were identified to start antiviral therapy. Age (OR 1.05, 95%CI 1.01-1.10), alanine aminotransferase (OR 2.53, 95%CI 1.14-5.62), lymphocyte percentage (OR 6.57, 95%CI 1.23-34.58), platelet count (OR 0.99, 95%CI 0.99-1.00), and international normalized ratio per (0.01) (OR 1.06, 95%CI 1.00-1.12) were identified to generate the nomogram, which showed the good discrimination (Development set: AUROC=0.755; Validation set: AUROC=0.707), calibration and clinical applicability. Patients with score >197 had high probability and those with score <0.132 had low probability for starting antiviral therapy.

**Discussion:** Antiviral therapy should be considered in gray zone patients and the non-invasive nomogram is promising for rapid screening patients who need antiviral therapy.

Biochemical and Serological Characterization of Chronic Hepatitis B Infection in Sylhet

MD Jahangir Alam1, Dr. Madhusudan Saha2, Dr. Masuma Mahatab3, Dr. M. K. Sur Chowdhury4

1Professor Sylhet Bangladesh, 2Professor, Department of Gastroenterology Sylhet, Sylhet MAG Osmani Medical College Bangladesh, 3Assistant Professor, Department of Radiology and Imaging Sheikh Hasina Medical College, Habibgonj, Sylhet Bangladesh, 4Associate Professor Sylhet, Sylhet MAG Osmani Medical College Bangladesh

**Introduction:** The World Health Organization (WHO) recognized hepatitis B virus globally as one of the commonest health problems [1]. Inactive or active chronic infection of hepatitis B virus can exaggerate the possibilities of hepatic insufficiency, end-stage liver disease including liver cirrhosis (LC) and hepatocellular carcinoma (HCC) [2].

**Objective:** This retrospective study was done to see biochemical and serological activity of hepatitis B virus in incidentally detected hepatitis B virus infected patients.

**Methods:** Available demographic and laboratory data of incidentally detected patients of chronic hepatitis B virus infection were retrieved from record and analysis using SPSS version 20. Mean and SD for continuous data and percentage of categorical data were calculated.

**Result:** Total 276 patients, age ranging from 13 to 60 years (mean 29.38), male 225 (81.5%) were enrolled. Of them 147 (53.3%) were in 26 - 40 years age group. In this series, 157 (56.9%) and 54 (19.6%) had history of saloon shave and family history of liver disease respectively. Alamine aminotransferase (ALT) of them varied from 15 to 367 IU/dl (mean 51.54). Of them 37 (13.4%) had HBeAg positive and 17 (6.2%) had fatty liver in ultrasound. HBV DNA was seen in 115 patients with 32 (27.8%) had DNA load above 100,000 copies per ml.

**Conclusion:** Asymptomatic and incidentally detected chronic hepatitis patients may have significant biochemical and serological viral activity requiring antiviral treatment.

Abstract Submission No. 101767
O-0119
Effectiveness of HBV Vaccination in Hemodialysis Patients negative for Anti-HBs
**Background:** Despite the national HBV vaccination program, hepatitis B (HBV) infection remains a significant health concern in Taiwan, especially in hemodialysis patients because of potential viral exposure. This study aimed to assess the effectiveness of HBV vaccination in hemodialysis patients negative for anti-HBs.

**Methods:** Hemodialysis patients without protective anti-HBs were prospectively enrolled from the National Taiwan University Hospital and local clinics, categorized as “HBV-naive” or “resolved-HBV” ([HBsAg negative, anti-HBc positive]). Engerix-B 40 mg was administered at 0, 1, 2, and 6 months. Serum anti-HBs level was evaluated at the first, 6th, and 12th month post full vaccination, and participants were categorizing as responders or non-responders (anti-HBs < 10 mIU/mL). Selected patients with a pre-study vaccine history received a booster vaccine.

**Results:** Between March 2019 and September 2023, 106 patients, with 100 completing the 4-dose vaccination, were enrolled. Among them, 65 were HBV-naive, and 35 had resolved-HBV. HBV-naive patients achieved anti-HBs > 10 mIU/mL at 58% (N=24/41), 70.4% (N=31/44), 76.3% (N=29/38), and 75% (N=27/36) at 1, 6, 12, and more than 12 months post-vaccination, respectively. Resolved HBV patients exhibited vaccine responses of 67.7% (N=21/31), 66.7% (N=10/15), 80% (N=4/5), and 33.3% (N=2/6), respectively. For 6 patients (5 HBV-naive, 1 resolved HBV) receiving a booster vaccination, the anti-HBs positive rate was 100% at the 12th month.

**Conclusion:** Hemodialysis patients lacking anti-HBs achieved 70% response rate to HBV vaccination in HBV-naive and resolved HBV groups. HBV vaccination for hemodialysis patients without protective anti-HBs is thus feasible and should be routinely implemented.

**ALG-000184 ± ENTECAVIR RESULTS IN SUBSTANTIAL HBV ANTIGEN DECLINES IN UNTREATED HBEAG+ HEPATITIS B**

Man-Fung Yuen1, Min Wu2, Edward Gane3, Kosh Agarwal4, Alina Jucov5, Junqi Niu6, Yanhua Ding3, Xie’Er Liang7, Kha Le8, Maida Maderazo9, Lawrence M. Blatt8, Sushimita Chandra9, Tse-I Lin9, Matthew McClure9, Jia-Ling Kao10

1Department of Medicine, School of Clinical Medicine, The University of Hong Kong Hong Kong China, 2Faculty of Medicine, University of Auckland Auckland New Zealand, 3King’s College Hospital, Institute of Liver Studies London United Kingdom, 4Arensia Exploratory Medicine SRL Chisinau Moldova, 5The First Hospital of Jinlin University Changchun China, 6Aligos Therapeutics, Inc. South San Francisco United States, 7Nanfang Hospital, Southern Medical University Guangzhou China

ALG-000184 is a prodrug of the potent (EC50=0.63 nM) capsid assembly modulator, ALG-001075.

Part 4 Cohorts 2 and B in Study ALG-000184-201 are evaluating oral daily 300 mg ALG-000184 doses ± entecavir (ETV) in a randomized, double blind, placebo-controlled (Cohort 2) or open label (Cohort B) manner, respectively, for 96 weeks. All Cohort 2 subjects receiving ETV monotherapy receive ALG-000184 + ETV beginning at Week 12. Here we report emerging data from untreated HBeAg+ CHB subjects who have received ALG-000184 + ETV x \( \leq 52 \) weeks.

22 subjects were enrolled in these 2 cohorts. At Week 52, ALG-000184 + ETV resulted in mean DNA and RNA reductions of 6.6 \( \log_{10} \) IU/mL and 4.4 \( \log_{10} \) copies/mL, respectively. The proportion of subjects achieving \( \geq 0.5 \) and \( \geq 1.0 \) \( \log_{10} \) declines at Week 52 were 100% and 59% for HBcrAg, 86% and 72% for HBeAg, 68% and 45% for HBsAg, respectively. No serious adverse events (AEs) or treatment emergent AEs (TEAEs) leading to discontinuation have been reported. The most frequent adverse events (AEs) were transaminase elevations (n=6), all of which resolved, returned to baseline or improved in the setting of continued dosing with study drug.

Substantial declines in HBV DNA/RNA and antigens have been observed in untreated HBeAg+ CHB subjects receiving 300 mg ALG-000184 ± ETV x \( \leq 52 \) weeks. These data suggest ALG-000184 may lower ccDNA levels and may play a central role in future regimens designed to achieve higher rates of functional cure.

Abstract Submission No. 101812

**O-0121**

**Major obstacles to “functional cure” with novel anti-viral therapy for CHB - a systemic review**

Jing Chen1, Dong Ji2, Ji-dong Jia3, Xinxin Zhang4, Fu-sheng Wang5, George Lau6

1JCSchool of Public Health and Primary Care, Faculty of Medicine, Chinese University of Hong Kong Hong Kong Hong Kong, 2Senior Department of Hepatology, Fifth Medical Center of Chinese PLA General Hospital Beijing China, 3Liver Research Center, Beijing Friendship Hospital, Capital Medical University Beijing China, 4Research Laboratory of Clinical Virology, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine Shanghai China, 5Treatment and Research Center for Infectious Diseases, The Fifth Medical Center of PLA General Hospital, National Clinical Research Center for Infectious Diseases Beijing China, 6Humanity and Health Clinical Trial Center, Humanity and Health Medical group Hong Kong SAR China

**Background:** New novel therapies targeting different steps in hepatitis B virus lifecycle are in clinical development for “functional cure”. This systemic review highlights key unresolved challenges to achieve such a cure.

**Methods:** We searched clinicaltrialsgov for interventional HBV trials in phases 1-3 posted January 1, 2018 - December 1, 2023. We further examined published results for novel anti-HBV compounds, focusing on antiviral strategies.

**Results:** The search yielded 238 records with 143 relevant to current review, covering 103 unique compounds across 15 categories. Analysis of 13 compounds with published results indicated that novel anti-HBV compounds were generally safe, but lacked a clear dose-response relationship in efficacy. Eleven out of 13 failed to achieve clinically significant and sustained declines in HBsAg levels. On-tx HBsAg decline from baseline (mean: 3.6 \( \log_{10} \) IU/mL) varied: -2.6 to 0.11 \( \log_{10} \) IU/mL, with maximum decline ranging from -0.33 \( \log_{10} \) IU/mL for CAM, -2.6 for siRNA, -2.0 for ASO to -0.11 for ASPINs. Off-treatment HBsAg decline was generally not sustained. One siRNA compound showed a 1% functional cure rate EOF, while control group
displayed a 2.2% rate. For one ASO (bepirovirsen, the only one entering phase 3), the dose-response relationship was unclear, with response divergence at week 8 among intervention groups, suggesting unknown confounding factors.

**Conclusion:** Few novel drugs led to HBsAg loss at EOT and even fewer achieved sustained off-tx HBsAg loss. The lack of evidence for a dose-response relationship underscores the importance of identifying unknown confounding factors for a “functional” cure in chronic hepatitis B patients.

**O-0122**

**ALG-000184 (100 mg) + ETV leads to stronger antiviral effects compared to ETV alone in HBeAg+ CHB**

**Jinlin Hou1, Xie’Er Liang1, Jia Xu2, Edward Gane3, Man-Fung Yuen4, Kosh Agarwal5, Min Wu6, Kha Le6, Maïda Maderazo6, Lawrence M. Blatt4, Sushimita Chanda4, Tse-I Lin6, Matthew McClure6, Yanhua Ding6**

1Nanfang Hospital, Southern Medical University Guangzhou China, 2The First Hospital of Jilin University Changchun China, 3Faculty of Medicine, University of Auckland Auckland New Zealand, 4Department of Medicin, School of Clinical Medicine, The University of Hongkong Hongkong China, 5King’s College Hospital, Institute of Liver Studies London United Kingdom, 6Aligos Therapeutics, Inc. South San Francisco United States

ALG-000184 is a prodrug of the potent (EC50 = 0.63 nM) HBV capsid assembly modulator, ALG-001075.

Part 4 Cohort 1 in Study ALG-000184-201 evaluated the safety and antiviral activity of 100 mg ALG-000184 + Entecavir(ALG-000184/ETV) vs. placebo + ETV for 12 weeks in a randomized, double blinded manner in untreated HBeAg+ CHB subjects. All subjects then received open label 100 mg ALG-000184 + ETV during Weeks 12-24 followed by an 8-week follow-up period, during which ETV monotherapy was administered. Eleven subjects randomized into the ALG-000184/ETV (N=8) and ETV (N=3) arms; baseline characteristics were similar. At Week 12, HBV DNA and RNA change from baseline (CBF) in ALG-000184/ETV and ETV arms were -5.3 vs. -4.0 log10 IU/mL and -2.8 vs. -3.0 log10 copies/mL, respectively. After adding ALG-000184, ETV subjects demonstrated similar CBF at Week 24 as ALG-000184/ETV subjects, -6.4 vs -6.9 log10 IU/mL (HBV DNA) and -3.9 vs -4.1 log10 copies/mL (HBV RNA), respectively. After switching to ETV monotherapy, antiviral effects diminished; the Week 8 follow up visit CBF was -5.2 log10 IU/mL for HBV DNA and HBV RNA returned to baseline. Three ALG-000184/ETV subjects exhibited a ≥0.4 log10 IU/mL (maximum reduction = 0.74 log10 IU/mL) HBsAg decline; HBsAg returned to near baseline levels after stopping ALG-000184. No serious adverse events (AEs) or discontinuations due to AEs were reported. All AEs were grade 1-2. Dosing of untreated HBeAg+ CHB subjects with 100 mg ALG-000184 + ETV x ≤ 24 weeks was well tolerated and had greater antiviral effects compared with ETV alone.

Hepatitis B surface antigen (HBsAg) is used to detect hepatitis B virus (HBV) infection in most screening programs. This testing strategy may overlook occult hepatitis B infection (OBI), which is a growing concern because of its transmissibility, clinical impact, and wide global
distribution. HBV gene variants linked to OBI have been identified; however, expense and time preclude in vitro functional definition. Seven pregnant women with OBI and four with overt HBV were investigated. Among the OBI cases, three mutations (K122I, T126N, and V177M) were discovered in the HBsAg "a" determinant region. Phylogenetic analysis showed that V177M, T126N, and K122I were HBV genotypes C and B, respectively. Serotyping showed ade for V177M, ayr for T126N, and unknown for K122I. Protein models were constructed using AlphaFold2, verified with Ramachandran plots, and refined with Galaxyme. Based on detected mutations, mutagenesis created models with above 95% validity for each mutant. Molecular dynamics simulation of the model proteins identified four pathways that caused HBsAg detection failure: altered protein compactness, altered residue interactions, impaired HBsAg double loop formation, and altered protein-solvent interactions. This study represents the few to employ in silico modelling and molecular dynamics to assess OBI-associated mutations, providing valuable insights for future research.

HBV recurrence after liver transplantation associated with non-compliance to “Up to seven” criteria
George Lau1, Dali Zhang2, Xi He2, Jing Chen3, Yudong Wang1, Gregory Cheng1, Hui Ren2, Zhenwen Liu1
1Humanity and Health Medical Group Hong Kong Hong Kong, 2Senior Department of Hepatology, Fifth Medical Center of Chinese PLA General Hospital Beijing China, 3JC School of Public Health and Primary Care, Faculty of Medicine, Chinese University of Hong Kong Hong Kong SAR China
Aim: To investigate risk factors for hepatitis B virus (HBV) recurrence after liver transplantation (LT) in patients with hepatocellular carcinoma (HCC).
Methods: This retrospective study analyzed patients with HCC secondary to HBV infection and had LT from February 15th, 2015 to February 18th, 2019 at a referral hospital. Patients were classified into those with HBV recurrence and those without. HBV recurrence was defined as HBV DNA or HBsAg positive. Univariate and multivariate analysis were used to explore the risk factors for HBV recurrence.
Results: A total of 112 eligible patients from February 15th, 2015, to February 18th, 2019, were included. Those with HBV recurrence after LT had higher prevalence of preoperative detectable HBV DNA (P = 0.001), microvascular thrombosis (P = 0.020), beyond “Up to seven” criteria (P < 0.001), longer maximum tumor diameter (6.3 cm vs. 2.0 cm, P = 0.001), a greater number of tumors (2.5 vs. 1.1, P = 0.017), and a more advanced TNM stage (III+IV: 58.3% vs. 16.5%, P = 0.001). Twelve (10.71%) patients experienced HBV recurrence after LT. The median recurrence time was 15.0 (6.5, 21.1) months after LT. All HBV recurrence were accompanied with HCC recurrence. Multivariate analysis highlighted that beyond “Up to seven” criteria (OR: 7.99, 95%CI: 1.19-53.49, P = 0.032), cholangiocellular carcinoma (OR: 116.7, 95%CI: 6.06-2250.5, P = 0.002) were independent risk factors for HBV recurrence.
Conclusions: HBV recurrence was associated with HCC recurrence. Preoperative HCC patients with beyond “Up to seven” criteria had higher risk for HBV recurrence after LT.

Background: A substantial proportion of patients with chronic hepatitis B (CHB) may fall into indeterminate phase. This study investigated the phase transition and disease progression of hepatitis B e antigen (HBeAg) negative CHB patients in indeterminate phase with normal alanine aminotransferase (ALT).

Methods: Four hundred and fourteen consecutive HBeAg-negative indeterminate phase CHB patients with normal ALT were retrospectively enrolled from three medical institutions. Significant liver fibrosis and cirrhosis were assessed by noninvasive indexes. The median age was 38.5 years and 54.3% were male. The proportion of patients transitioned to immune active phase, inactive phase and remained in indeterminate phase were 21.3%, 26.3%, and 52.4% after a median follow-up of 21.0 months, respectively. HBV DNA ≥20,000 IU/ml (HR 2.074, P=0.001) and HBsAg ≥1,000 IU/ml (HR 1.626, P=0.031) were significant predictors of transition to active phase. Eleven (25.0%) and 5 (11.4%) patients who transitioned to active phase progressed to significant liver fibrosis and cirrhosis respectively, while only one patient (0.8%) who remained in indeterminate phase developed significant liver fibrosis. Patients who transitioned to active phase (HR 32.093, P=0.001) had a higher risk of significant fibrosis development than those remained indeterminate.

Conclusions: About one fifth of HBeAg-negative indeterminate phase patients with normal ALT transitioned to active phase, and half of these patients remained in indeterminate phase. The levels of HBV DNA and HBsAg were significant predictors of phase transition. Transitioning to active phase had a higher risk of liver fibrosis and cirrhosis development in these patients.

Clinical outcomes of HBeAg-negative CHB patients with less than 100 IU/ml

Jian Wang¹,², Li Zhu³, Shaoqiu Zhang¹, Zhiyi Zhang¹, Tao Fan¹, Ye Xiong¹, Chao Jiang², Juan Xia¹, Xiaomin Yan¹, Xingxiang Liu², Chuangwu Zhu², Jie Li², Chao Wu³, Rui Huang³,⁴,⁵

¹Department of Infectious Diseases, Nanjing Drum Tower Hospital, Affiliated Hospital of Medical School, Nanjing University Nanjing China, ²Institute of Viruses and Infectious Diseases, Nanjing University Nanjing China, ³Department of Infectious Diseases, The Affiliated Infectious Diseases Hospital of Soochow University Suzhou China, ⁴Department of Infectious Diseases, Nanjing Drum Tower Hospital Clinical College of Nanjing University of Chinese Medicine Nanjing China, ⁵Department of Infectious Diseases, Nanjing Drum Tower Hospital Clinical College of Jiangsu University Nanjing China, ⁶Department of Hepatology, Huai’an No. 4 People’s Hospital Huai’an China

Background: HBsAg level <100 IU/ml and undetectable HBV DNA has been proposed as an alternate endpoint of “partial cure” in chronic HBV infection. We investigated outcomes of HBeAg-negative chronic HBV-infected patients with HBsAg <100 IU/ml and undetectable HBV DNA.

Methods: Consecutive untreated HBeAg-negative patients with chronic HBV infection with normal ALT and undetectable HBV DNA were enrolled from three medical institutions. Patients were divided into low HBsAg group (<100 IU/ml, “partial cure”, n=501) and high HBsAg group (≥100 IU/ml, n=717). Liver fibrosis was assessed by noninvasive tests (NITs) including APRI, FIB-4 or transient elastography.

Results: Of 1218 patients, the median age was 41.5 years and 51.3% were male. Patients with low HBsAg were older (45.0 vs. 40.0 years, P<0.001) than those in high HBsAg group, while NITs parameters including APRI, FIB-4 or transient elastography were comparable between groups. A total of 309 patients without significant fibrosis at baseline had available follow-up data. During a median follow-up 25.7 months, patients with low HBsAg were more likely to achieve HBsAg clearance (13.0% vs. 0%, P<0.001), while had a lower risk of significant liver fibrosis development (2.2% vs. 7.0%, P=0.020), compared to high HBsAg group. No patients developed HCC in both groups. Serum HBsAg <100 IU/ml was associated with higher chance of HBsAg clearance (HR 76.034, P=0.026) and low risk of significant fibrosis development (HR 0.045, P<0.002).

Conclusions: Patients with “partial cure” had favorable outcomes with a high rate of HBsAg clearance and low risk of fibrosis progression.
Multi-method analysis identifies genotypes in all evaluated participants on-NA, B-Together study

Jeong Heo1, 2, Maria Buti3, Leigh Felton4, Jerome Bouquet4, Maximillian Lee5, Thomas Greene6, Divya Lakshminarayanan6, Scott D. Speer6, Helene Plein4, Dickens Theodore6, Melanie Paff6, Susan Dixon4
1Department of Internal Medicine, College of Medicine, Pusan National University Busan Republic of Korea, 2Biomedical Research Institute, Pusan National University Hospital Busan Republic of Korea, 3Liver Unit, Hospital Vall d’Hebron and CIBER-EHD del Instituto Carlos III Barcelona Spain, 4GSK London UK, 5GSK South San Francisco USA, 6GSK Collegeville USA, 7GSK Durham USA

Background: In B-Together, 9-15% of participants with chronic hepatitis B virus (HBV) infection on background nucleos(t)ide analogs (NAs) receiving sequential bepirovirsen and pegylated interferon-α-2a (bepirovirsen+ Peg-IFN) therapy achieved the primary outcome of hepatitis B surface antigen (HBsAg) and HBV DNA ≤lower limit of quantification maintained for 24 weeks off-treatment. This post hoc analysis investigated HBV genotype (GT) using a three-tiered genotyping methodology.

Methods: HBV GTs in virally suppressed participants were determined using medical history, HBV sequencing, and a serology method (IMMUNIS® HBV Genotype EIA by Institute of Immunology Co.).

Results: The three methodologies had a high degree of concordance (75-100%) and determined GT for 101/108 (94%) participants. By contrast, medical history and HBV DNA/RNA sequencing alone were only successful in identifying GT in 50% of participants. GT-C and GT-D were the most common; GT-B the least (Table). GT-B (n=3/4) and GT-C (n=30/37) were predominantly identified in Asia; GT-A (n=14/16) and GT-D (n=30/34) in Europe. Virological response to bepirovirsen was observed across all common HBV GTs. Baseline HBsAg varied markedly by GT. Analysis of the relationship between HBV GT and treatment response is currently ongoing across studies exploring the efficacy of bepirovirsen-containing regimens.

Conclusions: This innovative three-tiered approach identified HBV GTs in all tested participants on NAs. GT analysis of participants in trials for novel HBV therapies is an important tool to understanding disease heterogeneity in chronic HBV infection.

ScRNAseq reveals high expression of CXCL8 resident immune cells with fibrosis in low HBsAg patients

Ravinder Singh1, Gayatri Ramakrishna1, Archana Rastogi2, Pramod Gautam2, Manor Kumar Sharma3, Shiv Kumar Sarin4, Nirupma Trehanpati5
1Institute of Liver and Biliary Sciences, New Delhi Delhi India

Background and Aims: Chemokine ligand 8 (CXCL8) is suggested as a potential biomarker in assessing the progression and severity of nCHBV patients. Analysis of CXCL8 expression in naïve CHBV patient’s liver and blood may provide insights of immune activation and inflammation.

Methods: We have included liver biopsies and plasma specimens from 36 naïve nCHBV patients, stratified into two groups based on HBsAg levels: Group I (HBsAg<9), n=9 with HBsAg <2000 IU/mL and Group II (HBsAg≥9, n=27) with HBsAg >2000 IU/mL, with HBV DNA < and >2,000 IU/mL, with increased ALT/AST >1.2 x ULN. Comprehensive histopathological analysis, quantification of plasma cytokine levels using cytokine bead array in all patients and single-cell RNA sequencing of liver biopsies in three patients in each group was performed.

Results: Patients with low HBsAg levels showed advanced mean fibrosis scores of 2.62±1.76, while high HBsAg patients had mean fibrosis scores of 0.68±0.87. Lower HBsAg levels correlated with increased IL-8 (p=0.027) compared to higher HBsAg levels in plasma. Single-cell RNA sequencing of liver biopsies from low HBsAg patients compared with high HBsAg patients revealed elevated CXCL8 expression (p=0.0007) associated with intrahepatic CD4 effector memory (p=0.038) and CD8 naïve (p=0.017) cells, contrasting with high HBsAg levels. Individuals with low HBsAg exhibited a correlation between high expression of CXCL8, IL-8, and a higher fibrosis score (p=0.008).

Abstract Submission No. 101967

O-0073
Conclusions: Intrahepatic CXCL8 from CD4 effector memory and CD8 naïve cells contribute to increased IL-8 secretion, contributing to advanced fibrosis in nCHB patients with low HBsAg.

Abstract Submission No. 102017

Virological and histological characteristics of chronic hepatitis B virus patients with normal ALT.

Abul Hayat Manik1, Momen Khan2, Faroque Ahmed2
1Hepatology Department, Dhaka Medical College Hospital Dhaka Bangladesh, 2Dhaka Medical College Hospital Dhaka Bangladesh

Background and aims: Patients with chronic hepatitis B virus (HBV) infection and persistently normal ALT levels have whether abnormal liver histology or not is crucial for treatment. At present worldwide available most of the guideline recommends treatment depending on serum ALT level, which may miss significant number of liver disease. We studied the ALT, HBV DNA levels, and spectrum of histologic lesions in such patients.

Methods: It was a cross sectional observational study among the chronic hepatitis B virus infected patients presented in the DMCH who shows persistently normal ALT and detected HBV DNA load. Total 104 patients were enrolled in the study and undergone liver biopsy (n=104; hepatitis B e antigen [HBeAg+], 82; hepatitis B e antigen [HBeAg−]) 22).

Results: Among 82 HBeAg negative cases, there were 12(14%) moderate chronic hepatitis and 26(31%) showed mild chronic hepatitis. HBeAg positive cases also 8(27%) had moderate chronic hepatitis and 8(36%) had mild chronic hepatitis. 62% of HBeAg-positive and HBeAg-negative patients persistent normal ALT had baseline HBV DNA levels of >3.3 log copies/mL. Serum HBV DNA level and spectrum of histological changes doesn’t correlate. 60 (73.1%) HBeAg negative and 14 (63.6%) HBeAg positive patients had Knodell score >7.

Conclusion: A fair proportion of patients with chronic HBV infection with persistent normal ALT have HBV DNA >3.4 log copies/ml and significant histologic fibrosis in both HBeAg positive and HBeAg negative groups. Use of ALT and HBV DNA levels without liver biopsy may miss histologically significant disease in a proportion of patients.

Abstract Submission No. 102039
O-0134

Investigation of HBV cccDNA-bound proteins in liver biopsies from HBV for Therapeutic targeting

Purnima Tyagi1, Jitendra Singh1
1Institute of Liver and Biliary Sciences New Delhi India

Aims: Present study aims to examine the potential roles of cccDNA-bound proteins in HBV reactivation, silencing and contribution to viral replication in the progression of the infection. Identification of cccDNA-bound proteins in both HBeAg-positive(high replicating group) and HBeAg-negative patients (Low replicating group) may aid in better management of HBV patients.

Methods: We obtained 14 liver biopsies from patients with chronic hepatitis B. We divided into two groups: HBeAg negative (n=7) and HBeAg positive (n=7). We also measured blood HBsAg levels (log10 IU/ml 3.21±1.09 >6 months) and HBV DNA levels (log10 IU/ml 4±1.09). The single-stranded portion of HBV cccDNA was used as a template to synthesise biotinylated DNA oligos. Nano liquid chromatography combined with mass spectrometry (nano LC/MS) was used after the pull down was used to extract cccDNA and binding proteins from the nuclear extract of liver tissues of HBeAg+ and HBeAg-patients.

Results: Out of the 300 bound proteins in the HBeAg+, a total of 900 were down-regulated (<0.5-fold) and 300 were considerably elevated (>2-fold). In HBeAg+ several proteins were found to be increased (>2-fold), whereas others were downregulated (<0.5-fold): cul4B, RACK1, DNA damaging binding protein 2, and repressor bound proteins DDX17, Ddx5, METTL4, and PRDX1. Using siRNA in vitro (HepG2.2.15), we were able to identify the top three proteins DDB2, RACK1, and Cul4B expressed in HBeAg positive group. These proteins were shown to be directly associated to the expression of HBV parameters such as HBsAg (p<0.001), HBcAg (p<0.001), pgRNA (p<0.005), HBV DNA (p<0.005), and cccDNA (p<0.005).

Conclusion: A correlation between viral load and cccDNA-bound proteins. The high viral replicating group validated the identification of DDB2, Cul4B, and RACK1 as new nuclear cccDNA-bound proteins for better management of HBV patients.

Abstract Submission No. 200111

Functional HBsAb responses induced by BRII-179 are strongly associated with improved HBsAb loss

Zhihong Gao1, Libo Yuan2, Jianping Li3, Rong Hu4, Peng Hu5, Wei Yue6, Fangfang Lv7, Yiwen Liu8, Chunming Li8, Yue Wu8, Weihong Liu8, Xiaofei Chen9, Qing Zhu4
1The Third Affiliated Hospital Sun YAT SEN University Guangzhou China, 2West China Hospital of Sichuan University Chendu China, 3Guangzhou Eighth People’s Hospital Guangzhou China, 4Public Health Clinical Center of Chengdu Chengdu China, 5The Second Affiliated Hospital of Chongqing Medical University Chongqing China, 6The First People’s Hospital of Yunnan Province Kunming China, 7Sir Run Run Shaw Hospital Hangzhou China, 8Brii Biosciences Limited Beijing China

Background: BRII-179, a therapeutic vaccine comprised of PreS1, PreS2 and S HbsAg, showed no new safety observation and improved HBsAg loss at end-of-treatment (PPS: 32.6% vs. 21.6%) and 12-week post EOT in a randomized, double-blind, placebo-controlled phase 2 study as an add-on therapy in CHB patients receiving PEG-IFNα. Here, we report the data on patients meeting NRTI discontinuation criteria. Methods: 114 Chinese HBsAg negative virally suppressed CHB patients partially responding to 24-28 doses of PEG were randomized 1:1 to BRII-179 or placebo every 3 weeks for 7 doses with PEG continued for another 24 weeks. Eligible patients with HBsAg <0.05 IU/mL for 2 consecutive assessments at 12-24 weeks post EOT would be eligible to discontinue NRTI.

Results: 3 (5.3%) vs 1 (1.8%) patient in BRII-179 vs placebo group had AEs that led to BRII-179/placebo discontinuation. 4 treatment related SAEs were reported including 2 related to PEG and 2 related to PEG and BRII-179. By 24-week post EOT, BRII-179 group had higher percentage of patients met NRTI discontinuation criteria (FAS: 26.3% vs. 15.8%) and earlier NRTI discontinuation. In addition, higher percentage of patients in BRII-179 group had maximum HBsAb titer ≥10 (45.6% vs. 14.0%) and ≥100 IU/L (19.3% vs. 3.5%). As previously reported, HBsAb ≥100 IU/mL was strongly associated with sustained HBsAg loss off-treatment.

Conclusion: BRII-179 add-on was generally safe and tolerated. It induced functional immune responses and may improve CHB functional cure.

**Everest Project’s 5-Year Update: Efficacy of PegIFN-a Therapy in HBeAg-CHB Patients in China**

Chan Xie1, Dong-Ying Xie1, Lei Fu2, Wen-Hua Zhang1, Jia Wei4, Guojun Li3, Jia-Hong Yang1, Xin-Yue Chen1, Jia-Bin Li3, Jia-Shang2, Yu-Juan Guan2, Yong-Fang Jiang2, Ying Guo1, Yi-Lan Zeng1, Zhi-Liang Gao1

1Third Affiliated Hospital of Sun Yat-sen University, Department of Infectious Diseases Guangzhou China, 2Xiangya Hospital Central South University Changsha China, 3Gansu Wuwei Cancer Hospital Wuwei China, 4Affiliated Hospital of Yunnan University Kunming China, 5The Third People’s Hospital of Shenzhen Shenzhen China, 6People’s Hospital of Deyang City Deyang China, 7Beijing Youan Hospital, Capital Medical University Beijing China, 8The First Affiliated Hospital of Anhui Medical University Hefei China, 9Henan Provincial People’s Hospital Zhengzhou China, 10Guangzhou Eighth People’s Hospital Guangzhou China

**Background and Aims:** This study aims to evaluate the efficacy and safety of pegIFNα-based therapy in real-world nucleoside analog (NA) treated chronic hepatitis B (CHB) patients and identify predictors for HBsAg loss by pegIFNα.

**Method:** The Everest Project, a multicenter real-world study in China, was previously introduced, focusing on the HBsAg loss of CHB (NCT04035837). Patients with over a year of NA therapy, HBV DNA <100 IU/ml, HBeAg negative, and HBsAg ≤1500 IU/ml were recruited starting in 2018. PegIFNα-2b monotherapy or combination-with NA was performed. The 5-year study enrollment has now concluded, and the latest research data is presented here.

**Results:** Out of the total 23,412 patients recruited, 15,896 were considered mITT group, 12,260 patients were included in the PP group. Of the total patients over 48-week treatment, 77.47% were male, with an average age of 41.77 years and a mean HBsAg baseline of 378.05 IU/mL. 3,864 patients achieved HBsAg loss. The HBsAg loss rates were 10.75%, 22.72%, 28.72% and 31.43% at 12, 24, 36, and 48 weeks in the PP group, respectively, higher than that in the mITT group (figure 1A, B). Factors predicting higher HBsAg loss included a lower HBsAg baseline, reduced HBsAg levels at 12 and 24 weeks, ALT flare at the 12-week mark, younger age, female gender, and a lower BMI (figure 1C).

There were no severe adverse events during this project.

**Conclusion:** HBsAg loss rate could be over 30% in NA-suppressed CHB patients by pegIFNα strategy. Baseline and on-treatment predictors can better guide the achievement of functional cure.

---

**First-in-human, first-in-class, Phase 1B preliminary safety data of VRON-0200, a novel checkpoint modifier containing immunotherapy, for HBV Functional Cure**

Sue L Currie1, Currie, SL2, Luber, AD3, Ertl, HC3, Gane, EJ4

1Medical Data Analytics Centre, Department of Medicine and Therapeutics, and Institute of Digestive Disease, The Chinese University of Hong Kong Hong Kong Hong Kong, 2Virion Therapeutics, LLC Newark, DE USA, 3The Wistar Institute Philadelphia, PA USA, 4New Zealand Liver Transplant Unit, Auckland City Hospital, University of Auckland New Zealand

**Background:** VRON-0200 is a therapeutic vaccine for hepatitis B virus (HBV) functional cure that contains a genetically encoded checkpoint modifier (herpes simplex virus type 1(HSV-1) glycoprotein D), fused with HBV core and polymerase antigens, to induce enhanced, broadened, and prolonged CD8+ T cell responses. Here we report the first-ever preliminary clinical data of VRON-0200 in patients with chronic HBV.

**Methods:** Chronic HBV-infected adult, virally suppressed patients, with HBsAg levels <500IU/mL, are randomized to receive 1x10^10vp of one of 2 different chimpanzee adenoviral vectors intramuscularly. Cohort 1a receives a prime, followed by a heterologous boost, on day 91; Cohort 1b receives only the prime. A higher dose cohort, Cohort 2 (5x10^10vp), following the same dosing schedule, will begin once 12 patients in Cohort 1 reach day 28. Study assessments include safety, virologic, and immunologic parameters through one-year post-prime vaccination.

**Results:** Six Cohort 1 patients have been randomized and received one dose of VRON-0200 (n=3 each viral vector); all male, 5 Asian, with mean age of 44 years (range: 41-49); 5 are HBeAg-. Patients are at varying stages of follow-up: all had Days 1, 7, and 14 visits, 5 had Day 28 visits, and 2 had Day 60 visits. As of Jan.12, 2024(Table 1), no AEs,
SAEs, TEAEs, or laboratory abnormalities (including clinically significant ALT elevations) have been reported.

**Conclusions:** In this first report of safety data from VRON-0200, the prime dose has been well tolerated, with no significant safety concerns to date. The study is ongoing, and additional Cohort 1 clinical data will be presented.

**Efficacy of hepatitis B vaccine in liver cirrhosis patients**

**Suđhamshu KC1,2, Niyanta Karki1,2, Pukar Thapa1,2, Dilip Sharma1**

1National Academy of Medical Sciences Kathmandu Nepal, 2Norvic International Hospital Kathmandu Nepal

**Aim:** The literature has shown that the vaccines against hepatitis B virus (HBV) are safe and effective in patients with liver cirrhosis (LC) but the data is lacking in our country. We aimed to evaluate the response to standard hepatitis B (HB) vaccination in LC of various etiologies and compare in different stages of LC.

**Method:** Consecutive patients of LC negative for hepatitis B surface antigen (HBsAg) and antibody to hepatitis B core antigen (Anti HBc total) were included. All patients received three doses of HB vaccine 20μg intramuscularly at zero, one, and six months interval. Anti-HBs antibody was measured after 90 days of last vaccine.

**Results:** A total of 214 patients with mean age 59.28±11.23 years were studied. Overall response rate was 92%. Response rates as per Child Pugh classes A, B and C were 98%, 100% and 61%. Ethanol related LC had less antibody response (44%) than other causes of LC (p=0.003). Poor immunogenicity was associated with low albumin and malnutrition (p=0.003). The response rate was also found to be decreased in older age group. There were no side effects except for soreness at injection sites in few patients.

**Conclusions:** Vaccine against HBV is safe in LC patients. Low level of albumin and presence of malnutrition was significantly associated with decreased vaccine response. As the age and liver disease progress, the response rate for HB vaccination was found to be weaker. We recommend correction of malnutrition and build up albumin level before vaccination to Child C cirrhosis patients.

Abstract Submission No. 100356

**Maternal infection with hepatitis B and maternal and neonatal outcomes**

**Tingting Peng1, Calvin Pan Pan1,2, Shi Ouyang1**

1The Fifth Affiliated Hospital of Guangzhou Medical University Guangzhou China, 2NYU Langone Health, NYU School of Medicine New York USA.

**Background:** The correlation between HBV carrier status and pregnancy, as well as neonatal outcomes is clinically concerned.

**Methods:** We conducted a retrospective cohort study to analyze the risk factors and independent predictors of maternal and infant outcomes. Propensity Score Matching (PSM) was performed using a 1:4 matching ratio between the HBsAg (+) group and the healthy group. Maternal infection with hepatitis B and maternal and neonatal outcomes is clinically concerned.

**Results:** A total of 5,871 pregnant women received perinatal services in our hospital from January 1, 2021, to December 31, 2022. After PSM, we included 445 mothers with HBsAg (+) and 1,780 healthy mothers. The two groups were comparable after PSM. Compared to healthy group, HBsAg (+) mothers had a higher likelihood of preeclampsia (4.0% vs. 2.2%), gestational diabetes (16.9% vs. 13.0%), intrahepatic cholestasis of pregnancy (ICP) (22.5% vs. 1.0%), and umbilical cord prolapse (0.2% vs. 0%) and had a significantly lower occurrence of oligohydramnios (6.7% vs. 9.9%) and thyroid dysfunction during pregnancy (6.3% vs. 9.7%) (all P<0.05). In multivariate logistic regression analyses confirmed a higher risk of ICP with HBV infection (OR 2.35, 95% CI 1.12-5.44). (P<0.05). Newborns of HBsAg (+) mothers had a significantly lower occurrence of birth defects (0.4% vs. 2.9%, P=0.05) compared to babies of healthy mothers. In the multivariate logistic regression analysis, maternal HBV infection was not found to be associated with birth defects (P>0.05). (See Figure 1, Table 1-3)

**Conclusions:** HBsAg is an independent risk factor for ICP. HBV infection does not lead to an increased risk of birth defects.

**Switching to TMF is effective for ETV or TAF monotherapy in patients with hypoviremia**
En-Qiang Chen1, Lan-Qing Li3, Jing Zhou1, Yu-Jing Li1, Cheng-Run Song1, Min He1, Yong-Hong Wang1, Xue-Zhong Lei1, Wei Jiang1
1West China Hospital, Sichuan university Chengdu China

Objective: Some patients treated with ETV or TAF monotherapy may experience hypoviremia. This study aims to observe whether switching to (tenofovir amibenafamide, TMF) monotherapy can further improve the antiviral treatment benefits of these CHB patients with hypoviremia.

Method: This is a retrospective study targeting CHB patients treated with ETV or TAF monotherapy for more than 1 year, but with serum HBV DNA consistently fluctuating between 20 and 2000 IU/mL. All enrolled patients voluntarily switched to TMF for further antiviral treatment and completed comprehensive examinations at least once every 6 months. The primary outcome measure was the undetectable rate of HBV DNA after 6 and 12 months of TMF treatment, while the secondary outcome measure was the incidence of renal tubular damage and dyslipidemia.

Result: A total of 73 patients were included, including 47 patients treated with ETV and 26 patients treated with TAF. Among them, there were 33 HBsAg-positive patients and 40 HBsAg-negative patients. After switching to TMF treatment for 6 months and 12 months, 69.9% (51/73) and 74.0% (54/73) of patients achieved HBV DNA <20 IU/mL, respectively. Compared to HBsAg-positive patients, HBsAg-negative patients switching to TMF treatment can achieve a higher proportion of complete virological response (19/33 vs. 32/40, P=0.038; 18/33 vs. 36/40, P<0.001). After 12 months of treatment, the abnormal rate of urinary b2 microglobulin was 16.4% (12/73), and the proportion of urinary b2 microglobulin increasing by three times the upper limit of normal value was 6.8%. The proportion of blood phosphorus below the lower limit of normal value was 19.2% (14/73). Although the levels of total cholesterol and low-density lipoprotein cholesterol increased compared to before treatment, the differences were not statistically significant.

Conclusions: CHB Patients treated with ETV or TAF experience hypoviremia, switching to TMF can help most patients achieve a complete virological response rate, with good patient tolerance.

HBV PreS1 Variant Mediates the Protective Effect of NTCP S267F Variant Against HCC in CHB Patients

Hsiang-Hsuan Chuang1,2,3, Ding-Lian Wang2,3, Mei-Hung Pan1, Chih-Jen Huang1, Hwai-I Yang1
1School of Medicine, Chung Shan Medical University Taichung Taiwan, 2Graduate Institute of Life Sciences, National Defense Medical Center Taipei Taiwan, 3Genomics Research Center, Academia Sinica Taipei Taiwan

Background: The S267F variant (rs2296651) in the human hepatitis B virus (HBV) entry receptor, sodium taurocholate co-transporting polypeptide (NTCP), has been previously associated with a reduced risk of hepatocellular carcinoma (HCC) development in individuals with chronic hepatitis B (CHB) infection. However, the mechanism by which the NTCP variant decreases the HCC risk remains unclear. We examined the DNA sequence of HBV preS1 domain, known as the NTCP binding domain, to assess its association with the protective effect of the S267F variant against HCC.

Methods: The HBV DNA preS1 sequences of 366 CHB patients, sequenced through PacBio, were analyzed via Cox regression, logistic regression, and mediation analysis to predict HCC risk and evaluate the mediation effect of the HBV preS1 allele.

Results: Within the HBV preS1 domain sequence, a significant difference in the allele frequency of the adenine nucleotide at position 2956 (2956A) was observed between individuals with S267F GG genotype (mean ± SD: 0.35 ± 0.47) and those with GA/AA genotype (0.60 ± 0.43; p<0.001). Moreover, individuals with a higher allele frequency of 2956A demonstrated a reduced risk of HCC development (HR: 0.45; 95% CI: 0.29-0.69). The subsequent mediation analysis revealed that the 2956A served as a mediator in the protective effect of S267F variant against HCC, with more significant protection in the average causal mediation effect (ACME; OR: 0.87; p<0.001) than the average direct effect (ADE; OR: 1.07; p=0.28).

Conclusions: The allele 2956A within the HBV DNA preS1 domain might mediate the NTCP S267F variant against HCC.

Histological Characteristics in Functional Cure Post PEG-IFN-based Therapy

Na Gao1, Haishi Wu1, Mozuo nian1, Qiyi Zhao1, Zhiliang Gao1
1Department of Infectious Diseases, Third Affiliated Hospital of Sun Yat-Sen University Guangzhou China

Background: HBsAg seroclearance is associated with disease remission after treatment cessation. However, the histologic characteristics in patients with PEG-IFN-inducing HBsAg seroclearance have not been explored before.

Methods: Liver tissues obtained from patients with functional cure post PEG-IFN-based therapy (n=70). Liver pathology was evaluated by Scheuer. Intrahepatic HBsAg and cccDNA were analysed.

Results: There were 61 patients with chronic hepatitis B (CHB) and 9 patients with compensated cirrhosis received PEG-IFN based therapy and attained functional cure. Notably, 1/9 patients with prior compensated cirrhosis achieved fibrosis regression which verified by both histopathology and B ultrasound after attaining HBsAg seroclearance. In patients who have achieved a functional cure from prior CHB, it demonstrated that 13.1% and 1.6% of them presented with moderate and severe intrahepatic inflammation, respectively. Furthermore, 36.1% and 1.6% of these patients illustrated moderate fibrosis and severe fibrosis, respectively. The age, gender, NAFLD, intrahepatic HBsAg and cccDNA level between intrahepatic inflammation and none-inflammation groups showed no statistic difference. Eight functionally cure patients experienced HBsAg seroreversion. HBsAg seroreversion group exhibited a higher level of cccDNA at cessation time of PEG-IFN, with a median (Q1, Q3) of 2.2 (0.79-2.84) log copies/10^3 cells, compared to none HBsAg seroreversion group (0.96, 0-2.06 log copies/10^3 cells, P = 0.028).

Conclusion: HBsAg seroclearance contributes to fibrosis remission in patients with prior compensated cirrhosis however, part of patients with prior chronic hepatitis B remained inflammation and fibrosis, and it warrant further study to investigate the potential influencing factors of residual inflammation.

Antiviral therapy can improve the health-related quality of life in CHB patients with normal ALT
En-Qiang Chen1, Jing Zhou1, Lan-Qing Li1, Yu-Jing Li1, Cheng-Run Song2, Xue-Zhong Lei1, Tao-You Zhou1, Hong Tang3

1West China Hospital, Sichuan university Chengdu China

Objective: To investigate the impact of chronic HBV infection on the quality of life of patients, and whether antiviral therapy can improve the quality of life of CHB patients

Method: This is a prospective study targeting CHB patients with persistent normal ALT, negative HBeAg, and positive HBV-DNA. The quality of life was evaluated using the Specific HBV Infected Person Quality of Life Scale (HBQOLV1.0). Patients need to complete the quality of life scale at baseline and 12 months after enrollment.

Result: A total of 244 patients finally included, with 59 in untreated group and 185 in treated group. At baseline, there was no significant difference in the total HBQOL scores between the treatment and untreated groups (2121.5 vs. 2140.6, P=0.844). The average scores of the two groups of patients in six dimensions of psychological status, expected anxiety, contagiousness and health vulnerability, vitality, and sense of shame were all less than 75 points, and the scores of the first four dimensions were less than 70 points. After 12 months of follow-up, the total HBQOL score of the untreated group increased compared to baseline (2121.5 vs. 2140.6, P=0.380), but the difference was not significant. Except for the dimension of shame, the other five dimensions were higher than the baseline, but the difference was not significant. After 12 months of treatment, the total score of HBQOL in the treatment group increased with statistical significance (2280.7 vs. 2121.5, P=0.001). Except for the vitality dimension, the average scores of the remaining five dimensions were all higher than the baseline, and the differences were statistically significant. Among them, expected anxiety (65.0 vs. 71.4, P<0.001), contagiousness (66.8 vs. 74.2, P<0.001), and sense of shame (74.4 vs. 79.9, P=0.003) showed significant improvement, with a score increase of 5 points compared to before treatment.

Conclusion: Chronic HBV infection reduces the health-related quality of life. Antiviral therapy can improve the negative effects of HBV infection on patients in terms of psychological status, expected anxiety, shame, contagiousness, and health vulnerability.

Abstract Submission No. 100453

Anti-fibrosis effect of traditional Chinese medicine compound Biejiaruangan in CHB patients

En-Qiang Chen1, Ya-Chao Tao1, Meng-Lan Wang1, Dong-Mei Zhang1, Juan Liao1, Ming He1, Xing Cheng1, Hong Tang3

1West China Hospital, Sichuan university Chengdu China

Aims: Compound Biejiaruangan (CBJRG) tablet can be used to treat liver fibrosis. This study aimed to investigate the anti-fibrosis effect of CBJRG in patients with chronic hepatitis B (CHB).

Patients and Methods: Eligible patients were divided into the Without group and the With CBJGR group based on whether the CBJRG was present in the treatment regimen. The differences of live stiffness measurements (LSM) values, aspartate aminotransferase-to-platelet ratio index (APRI) scores and fibrosis index based on four factors (FIB-4) scores were compared between the baseline and the week 24 in the Without and the With CBJRG groups, and in the entecavir (ETV) and the ETV plus CBJRG groups.

Results: LSM values and APRI scores were significantly decreased in the With CBJRG group after 24-week treatment, while only LSM values were reduced in the Without group. The improvement of fibrosis stages was only observed in patients receiving 24-week CBJRG in the context of ETV antiviral therapy, not in patients receiving CBJRG plus other antiviral drugs. Moreover, LSM values at week 24 were decreased as compared to the baseline in the ETV group, whereas no differences of APRI and FIB-4 scores were observed. LSM value, APRI and FIB-4 score were all statistically lower in patients treated with ETV plus CBJRG. The percentage of patient with fibrosis F4 were significantly lower in the ETV plus CBJRG group when compared to the ETV group.

Conclusion: The CBJRG plus ETV combination treatment shows a stronger anti-fibrosis efficacy than ETV alone in patients with CHB.

Pan-genotypic association of G1896A mutant with HBV DNA or advanced liver diseases: a meta-analysis

Guixin Li1, Xin Liu2, Hongsong Chen1, Fengmin Lu1,2

1Peking University People’s Hospital, Peking University Hepatology Institute, Beijing Key Laboratory of Hepatitis C and Immunotherapy for Liver Disease, Beijing International Cooperation Base for Science and Technology on NAFLD Diagnosis Beijing China, 2Department of Microbiology and Infectious Disease Center, School of Basic Medical Sciences, Peking University Beijing China

Background: G1896A is one of the most common mutations in hepatitis B virus (HBV) genome, resulting in the abolishment of HBeAg production. Numerous studies focused on the replicative capacity and pathogenicity of G1896A mutant, but the conclusions were not consistent.

Methods: We searched Pubmed, Embase and Cochrane library up to June 18, 2022. Studies were screened according to inclusion and exclusion criteria. Extracted data were analyzed with the fixed- or random-effects model. Potential sources of heterogeneity were investigated using sensitivity and subgroup analyses.

Results: 63 studies were finally included to conduct meta-analyses. Results showed that G1896A mutant was more prevalent in HBeAg negative patients (OR=5.57; 95%CI, 3.86~8.04; P<0.001). And G1896A was likely more common in genotype B and C than genotype D. Serum HBV DNA load of HBeAg-negative patients with G1896A mutant was 0.87 log10copies/mL higher than those without mutant (WMD=0.87; 95%CI, -1.56~0.18; P=0.014). Moreover, G1896A mutant was closely associated with advanced liver diseases including liver cirrhosis (OR=1.96; 95%CI, 1.67~2.29; P=0.001) and hepatocellular carcinoma (OR=1.60; 95%CI, 1.20~2.12; P=0.001). These findings were constant in genotype B and/or C (liver cirrhosis: OR=2.47; 95%CI, 1.95~3.13; P<0.001; hepatocellular carcinoma: OR=1.61; 95%CI, 1.08~2.40; P=0.021).

Conclusions: HBeAg-negative patients with G1896A mutant might have higher HBV DNA level and G1896A mutant was closely associated with advanced liver diseases in chronic HBV-infected patients. In the area with high incidence of G1896A mutant, especially Eastern and Southeastern Asia, chronic HBV-infected patients should be monitored on mutants and expected to receive early antiviral treatment.

Background: The coexistence of chronic hepatitis B (CHB) and hepatic steatosis (HS) is common, but simple non-invasive diagnostic methods to accurately assess hepatic inflammation severity are lacking. This study aimed to establish a non-invasive diagnostic model for hepatic inflammation in CHB patients with concurrent HS using machine learning (ML).

Methods: This study consecutively enrolled treatment-naïve CHB patients with concurrent HS who underwent liver biopsy from eleven medical centers between April 2004 and September 2022. Nine centers were used for training, while the other two centers were for external validation (validation cohort 1, validation cohort 2). Four ML algorithms (LR, RF, GBC, and ADB), were used to predict inflammation degree. Those patients with predicted inflammation grade (G) ≥ 3 were diagnosed. The optimal features for model development were selected by Shapley Additive explanation. Area under curve (AUC) was calculated to confirm the accuracy of the models.

Results: A total of 1,639 CHB patients with concurrent HS were enrolled in the study. In the training cohort, 157 (22.79%) patients reported hepatic inflammation ≥ G3, respectively. In validation cohort 1, 31 patients (6.09%) had hepatic inflammation ≥ G3. Meanwhile, in validation cohort 2, 76 (17.23%) patient exhibited hepatic inflammation ≥ G3. The GBC model had the best performance in diagnosing inflammation ≥ G3, with AUC of 0.856 (95% CI 0.830-0.883) in the training cohort, 0.892 (0.865-0.919) in validation cohort 1 and 0.775 (0.736-0.814) in validation cohort 2.

Conclusions: The GBC model reliably predicts inflammation ≥ G3 in CHB patients with concurrent HS, improving disease diagnosis and management.
booster immunity further improved the positive rate and antibody titer of PCLD, especially among patients with primary immunity failure. Local and systemic adverse reactions were slight.

Immunogenicity Of A Booster SARS-CoV-2 Vaccination In Patients With Chronic Liver Disease

Qi Qian Li1, Huiling Xiang1, Jing Chen2, Kai Sun3, Ruixin Song2, Jiayin Wang1, Hongmin Lv1, Yankai Yang1, Jing Liang1, Chao Yang1

1Tianjin Third Central Hospital Tianjin China, 2The Third Central Clinical College of Tianjin Medical University Tianjin China, 3Tianjin Hongqiao Hospital Tianjin China

**Objective:** To investigate the safety and immunogenicity of the severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) vaccine booster in patients with chronic liver disease.

**Design:** Patients with chronic liver disease who received a SARS-CoV-2 vaccine booster were enrolled. Adverse events within 14 days of any dose of SARS-CoV-2 vaccine were recorded, simultaneously, serum samples were collected from enrolled patients at least 14 days after the booster dose and tested for SARS-CoV-2 neutralizing antibody (novel coronavirus neutralizing antibody, nCoV NTAb) and IgG antibody against SARS-CoV-2 spike binding domain (novel coronavirus Spike Receptor-binding Domain antibody, nCoV S-RBD) levels.

The data of liver and kidney function, blood routine and coagulation function were collected and statistically analyzed before and after the booster injection of nCoV vaccine.

**Results:** A total of 114 patients with chronic liver disease were included. The positive rates of nCoV NTAb and nCoV S-RBD in patients with chronic liver disease were 87.72% and 91.23% after the booster injection of COVID-19 vaccine, and the positive rates of nCoV NTAb and nCoV S-RBD in non-cirrhotic group and cirrhotic group were 93.55%, 80.77% and 98.39%, 82.69%, respectively (p<0.05); the median nCoV NTAb levels in non-cirrhotic group and cirrhotic group were 31.41AU/mL and 32.64AU/mL, and the median nCoV S-RBD levels were 102.94AU/mL and 119.41AU/mL, respectively. The results of continuous antibody level monitoring in 22 patients with basic immunization showed that after booster injection of COVID-19 vaccine increased significantly from 6.18% to 90.91%. Antibody levels in patients with chronic liver disease increased significantly after the booster injection of COVID-19 vaccine compared to pre-injection levels. The nCoV-NTAb antibody levels increased evidently from 11.24 AU/mL (4.41 AU/mL - 38.26 AU/mL) to 59.14 AU/mL (5.72 AU/mL - 279.38 AU/mL) in 22 patients after the booster, with a mean increase of 5.26-fold. The median nCoV-SRBD antibody level increased significantly from 27.27 AU/mL (2.90 AU/mL - 169.47 AU/mL) to 219.10 AU/mL (2.55 AU/mL - 579.46 AU/mL) (p<0.01), with a mean increase of 8.03-fold. The booster injection resulted in the production of nCoV-NTAb in 66.7% (6/9) of patients with chronic liver disease who failed basic immunization and nCoV-SRBD antibody in 71.43% (7/9). The overall tolerability of COVID-19 vaccine in patients with chronic liver disease was good, with a low incidence of adverse reactions and systemic adverse reactions were slight, with local pain at the injection site being the most frequent adverse reaction.

**Conclusion:** After basic SARS-CoV-2 immunization, the booster SARS-CoV2 vaccine can increase the serum conversion rate and antibody level of neutralizing antibodies and S-RBD IgG antibodies in patients with chronic liver disease (including patients with cirrhosis). The adverse reactions are mild and acceptable. The severity of liver disease is related to the immune response to COVID-19 vaccine.

1Nanjing Drum Tower Hospital Clinical College of Nanjing University of Chinese Medicine, Nanjing, Jiangsu, China Nanjing China, 2Institute of Viruses and Infectious Diseases, Nanjing Medical University, Nanjing, Jiangsu, China Nanjing China, 3Cedars-Sinai Medical Center, Los Angeles, California, USA Los Angeles USA, 4Shandong Provincial Hospital, Shandong University, Jinan, Shandong, China Jinan China, 5School of Computer Science, China University of Geosciences, Wuhan, Hubei, China Wuhan China, 6Shandong Provincial Hospital Affiliated to Shandong First Medical University, Jinan, Shandong, China Jinan China, 7Zhongda Hospital, Medical School, Nanjing, Jiangsu, China Nanjing China, 8The Affiliated Hospital of Hangzhou Normal University, Hangzhou, Zhejiang, China Hangzhou China, 9Nanjing Drum Tower Hospital, Affiliated Hospital of Medical School, Nanjing University Nanjing China

**Background:** We previously developed a diagnostic model named PAP to assess advanced fibrosis (≥S3) and cirrhosis (≥S4) for chronic hepatitis B (CHB) patients with hepatic steatosis (HS). The PAP model was built on Gaussian naive bayes including prothrombin time, albumin and platelet. This study aimed to test the stability of the PAP model across five subgroups.

**Methods:** A total of 1,427 patients from nine clinical centers in China (NCT05766449) were enrolled. Patients were divided into five groups according to age (<40 and ≥40 years), sex (males and females), body mass index (<25 kg/m² and ≥25 kg/m²), hepatitis B e antigen (HBeAg) status (positive and negative) and hepatitis B virus deoxyribonucleic acid (HBV DNA) level (<10⁵ and ≥10⁶ IU/mL).

**Results:** In the training cohort, the PAP model had the highest area under curves (AUCs) in patients with HBV DNA ≥10⁶ IU/mL at 0.827 (95% CI 0.749-0.905) for ≥S3 and 0.864 (95% CI 0.794-0.934) in patients aged ≥40 years for ≥S4, while it performed modestly in patients with HBV DNA <10⁵ IU/mL when diagnosing ≥S3. In the validation cohort, it had the highest AUC of 0.824 (95% CI 0.765-0.883) in patients with HBV DNA ≥10⁷ IU/mL, and the lowest AUC of 0.687 (95% CI 0.619-0.755) in patients aged <40 years for ≥S3. The model performed best in female patients for =S4, with an AUC of 0.954 (95% CI 0.902-1.000).

**Conclusions:** In CHB patients with HS, the PAP model remained its stability for diagnosing liver advanced fibrosis and cirrhosis across various groups.

Novel algorithms for Predicting Advanced Fibrosis in CHB Patients with Concurrent Hepatic Steatosis
Abstract Submission No. 100595

The diminished accuracy of non-invasive tests for significant fibrosis in CHB patients with MASLD

Wenjing Ni1,2, Fajuan Rui1,2, Youwen Tan3, Liang Xu4,5,6, Junping Shi1, Jie Li1,2,8

1Department of Infectious Diseases, Nanjing Drum Tower Hospital; 2Clinical College of Nanjing University of Chinese Medicine; 3Department of Hepatology, Tianjin Second People’s Hospital; 4Tianjin Medical University; 5China Tianjin China; 6Department of Infectious Diseases, The Affiliated Hospital of Hangzhou Normal University; 7Department of Infectious Diseases, Nanjing Drum Tower Hospital; 8Affiliated Hospital of Medical School, Nanjing University, Nanjing, Jiangsu, China Nanjing China

Background: The co-existence of chronic hepatitis B (CHB) and metabolic dysfunction-associated steatotic liver disease (MASLD) has become popular, exacerbating the progression of hepatic fibrosis. However, the diagnostic performance of non-invasive tests (NITs), including the fibrosis-4 index (FIB-4), aspartate aminotransferase-to-platelet ratio index (APRI), and non-alcoholic fatty liver disease fibrosis score (NFS), remains uncertain in CHB patients with MASLD. This study aims to evaluate the accuracy of these NITs in identifying significant fibrosis in such population.

Methods: This multicenter, cross-sectional study was conducted at eleven Chinese hospitals. The whole population was classified as three groups, with group A of CHB patients combined with simple hepatic steatosis (HS), group B of CHB patients with MASLD involving 1-3 cardiometabolic risk factors (CMRFs), and group C of CHB patients with MASLD involving 4-5 CMRFs. According to Scheuer’s classification, ≥S2 was defined as significant fibrosis.

Results: A total of 1,079 eligible patients were enrolled. In group A, the optimal cut-off values for FIB-4, APRI, and NFS in diagnosing ≥S2 were 1.263, 0.56, and -3.547, respectively, with corresponding area under curves (AUCs) of 0.784, 0.786 and 0.723. In group B, the AUC of FIB-4, APRI, and NFS was 0.655, 0.677 and 0.634, respectively. These AUCs further declined in group C, all falling below 0.640 (Figure 1).

Conclusions: The diagnostic accuracy of the three NITs diminished as the number of CMRFs increased. More studies are needed to develop tailored NITs for specific population.

Abstract Submission No. 100606

Comparison of Markers for Diagnosing Significant or Advanced Fibrosis in Patients with CHB

Xiaoming Xu1,2, Fajuan Rui1,2, Wenjing Ni1,2, Chao Wu1,2, Junping Shi1, Yee Hui Yeo4, Jie Li1

1Nanjing Drum Tower Hospital, Affiliated Hospital of Medical School, Nanjing University Nanjing China; 2Nanjing Drum Tower Hospital Clinical College of Nanjing University of Chinese Medicine Nanjing China; 3Affiliated Hospital of Hangzhou Normal University Hangzhou China; 4Cedars-Sinai Medical Center Culver City United States

Background: Non-invasive tests (NITs) are limited by having a significant proportion of indeterminate results for screening fibrosis in chronic hepatitis B (CHB) patients with concurrent hepatic steatosis (HS). Herein, we aimed to establish novel algorithms that call for improvements in current diagnostic workflow.

Methods: We consecutively recruited untreated patients who underwent liver biopsy from nine medical centers in China between April 2004 and September 2021 (Clinical Trials: NCT05766449). Fibrosis index based on the four factors (FIB-4), aspartate aminotransferase to platelet ratio index (APRI) and NAFLD fibrosis score (NFS), as well as their combinations were used to predict advanced fibrosis. Sensitivities, specificities, and positive and negative predicted values were calculated. Subsequently, we computed the proportion of patients with the correct classification (the sum of true positives and negatives) for different combinations of NITs.

Results: Among 926 treatment-naive CHB patients with HS, 180 (19.44%) patients had advanced fibrosis. At the lower cut-off values, APRI exhibited the highest sensitivity of 65.56%, followed by FIB-4 (53.89%) and NFS (41.11%). At the higher cut-off values, NFS had the highest sensitivity of 65.56%, followed by FIB-4 (53.89%) and APRI (49.1%). Notably, APRI displayed the highest indeterminate rate of 30.99% compared to other NITs. The proportions of patients to receive a correct classification according to a single test were 64.7% for NFS, 64.1% for FIB-4, and 57.6% for APRI. When combining the test, the algorithm with NFS followed by APRI enabled most patients to receive a correct classification (73.7%), compared to FIB-4-NFS (71.3%), NFS-FIB-4(71.8%), FIB-4-APRI (71.0%), APRI-FIB-4 (70.5%), APRI-NFS (71.8%).

Conclusion: The combined model NFS-APRI developed in our study showed better performance than individual NITs, which could reduce indeterminate zones and optimize referral pathways.

Abstract Submission No. 100595

O-0154

The diminished accuracy of non-invasive tests for significant fibrosis in CHB patients with MASLD

Fibrosis in Patients with CHB
HBsAg decline in Peg-IFN treated hepatitis B with fatty liver is similar to non-fatty liver patients

Jiayin Wang1, Qing Ye1, Weili Yin1, Fang Wang1, Hongming Lv1, Jing Liang1, Yanying Gao1, Fei Tang1, Tinghong Li1, Lei Liu1, Yan Li1, Yankai Yang1, Ying Li1, Jun Li1, Huiling Xiang1
1Department of Gastroenterology and Hepatology, Tianjin Third Central Hospital, Tianjin Key Laboratory of Extracorporeal Life Support for Critical Diseases, Institute of Hepatobiliary Disease, Tianjin China

Objective: To explore the decrease of HBsAg in patients with hepatitis B with fatty liver during Peg-interferon therapy.

Methods: Patients treated with Peg-IFN for 48W were collected. According to the fat attenuation, the enrolled people were divided into fat attenuation <240dB/m group (n=116) and fat attenuation ≥240dB/m group (n=150). Statistical analysis of data was performed by SPSS 26.0 software.

Results: The median age of our study was 40 (36-48) years old, including 79 males (75.98%), 130 treated patients (67.82%), 143 HBV-DNA negative patients (59.09%), 121 HBeAg negative (80.13%), and the median HBsAg was 3.02 (2.58-3.42) Log10 IU/mL, the median ALT 24 (17-38.75) U/L; There were significant differences in gender and age between fat attenuation <240dB/m group and fat attenuation ≥240dB/m group. At follow-up up to 48W, there was no significant difference in the overall decline of HBsAg between the fat attenuation <240dB/m group and fat attenuation ≥240dB/m group, and the decline slope was (-0.020 vs -0.016) respectively. However, the decrease rate of HBsAg in the fat attenuation <240dB/m group was greater than that in the fat attenuation ≥240dB/m group at 24W (75.48% vs 52.05%, P=0.05); There was no significant difference in HBsAg clearance between the two groups at 12W, 24W, 36W and 48W. Stratified analysis showed that there were no significant differences in the overall decrease of HBsAg and the HBsAg clearance rate between 12W, 24W, 36W and 48W in terms of gender, age (<40 or not), treated/non-naive patients, HBVDNA positive/negative, HBeAg positive/negative, and HBsAg (>1500IU/ml or not), between fat attenuation <240dB/m group and fat attenuation ≥240dB/m group. Among the HBeAg negative patients, and the baseline ALT normal, the decrease of HBsAg in the fat attenuation <240dB/m group was significantly greater than that in the fat attenuation ≥240dB/m group at 24W. For the baseline ALT abnormal, the 48W HBsAg decline in fat attenuation <240dB/m group was greater than that in fat attenuation ≥240dB/m group, and the slopes were (-0.019 vs -0.011, P=0.020).

Conclusion: In the general population, compared with non-fatty liver group, there was no significant difference in HBsAg overall decline and the HBsAg clearance in patients with hepatitis B with fatty liver. For the baseline ALT abnormal, the 48W HBsAg decline in fatty liver group was greater than non-fatty liver group.

Analysis of PLT changes in patients with cirrhotic hepatitis B patients treated with Peg-interferon

Jiayin Wang1, Qing Ye1, Weili Yin1, Fang Wang1, Hongming Lv1, Jing Liang1, Yanying Gao1, Fei Tang1, Tinghong Li1, Lei Liu1, Yan Li1, Yankai Yang1, Ying Li1, Jun Li1, Huiling Xiang1
1Department of Gastroenterology and Hepatology, Tianjin Third Central Hospital, Tianjin Key Laboratory of Extracorporeal Life Support for Critical Diseases, Institute of Hepatobiliary Disease, Tianjin China

Objective: To explore the decrease of PLT in patients with compensatory cirrhosis during Peg-interferon therapy.

Methods: Patients treated with Peg-IFN for 48W were collected. Liver stiffness measurement (LSM) was measured by instantaneous elastic imaging. The enrolled people were divided into LSM<9kPa group (non-cirrhotic patients) (n=171) and LSM≥9kPa group (compensatory cirrhosis group) (n=83). Statistical analysis of data was performed by SPSS 26.0 software.

Results: The median age of our study was 40 (36-48) years old, including 79 males (75.98%), 137 treated patients (67.82%), 143 HBV-DNA negative patients (59.09%), 121 HBeAg negative (80.13%), and the median HBsAg was 3.02 (2.58-3.42) Log10 IU/mL, the median ALT 24 (17-38.75) U/L; PLT at 12W decreased significantly from baseline in both groups, The decrease of 12W PLT from baseline in LSM<9kPa group was significantly higher than LSM≥9kPa group (49.84% vs 45.48%, P=0.010). In the LSM≥9kPa group, the highest 12W decrease from baseline was 79%. PLT in 24W, 36W and 48W groups showed a slow upward trend compared with 12W, and the upward trend of PLT in the two groups was similar. Stratified analysis showed that there were significant differences in the patients with male age >40, naïve treatment, HBsAg >1500IU/mL, abnormal ALT in baseline, the decrease of 12W PLT from baseline in the LSM≥9kPa group was significantly higher than LSM<9kPa group, In these populations, we should pay more attention to the decline of 12W PLT and detect serious PLT reductions in time.
**Conclusion:** in the patients with male, age > 40, naïve treatment, HBsAg > 1500 IU/mL, abnormal ALT in baseline, we should pay more attention to the decline of 12W PLT in the LSM ≥ 9 kPa group.

pgRNA and HBcAg closely correlated with cytokines in HBeAg-positive pregnant patients in pregnancy</st>

Qiao Tang1, Chunrui Wang1, Peng Hu1  
1The Second Affiliated Hospital of Chongqing Medical University Chongqing China

**Background:** Previous studies indicated hepatitis B virus (HBV) serum markers are associated with host immunity. However, the relationship of novel HBV serum markers pregenomic RNA (pgRNA) and HBcAg with host immunity in pregnancy CHB patients remains unclear. Therefore, we aimed to explore the relationship between novel HBV serum markers (pgRNA and HBcAg) and cytokines in HBeAg-positive pregnant chronic hepatitis B (CHB) patients during pregnancy.

**Methods:** In this retrospective real-world study, HBsAg, HBV DNA, pgRNA, HbcAg and 28 cytokines were collected from 28 HBeAg-positive pregnant CHB patients at 24-28 weeks gestation.

**Results:** We found that neither HBsAg, HBV DNA, nor HBcAg correlated with cytokines, but only pgRNA positively correlated with Th1 cytokines (IFN-γ, IL12p70, IL2 and TNF-α), Th2 cytokines (IL10 and IL5), Th17 cytokine (IL21), and cytokines regulating cell proliferation and differentiation (CTLA4, IL15, IL23 and TGF-β1), and negatively associated with IL12p40 in 24-28 weeks gestation. In HBeAg-positive pregnant CHB patients younger than 30 years old, pgRNA correlated with Th1 cytokines (IFN-γ and IL12p70), Th2 cytokines (IL5), Th17 type cytokines (ICOS) and cytokines regulating cell proliferation and differentiation (CTLA4 and TGF-β1), HbcAg and HBsAg correlated with ICOS, and HBV DNA correlated with ICOS and CTLA4. In patients older than 30 years, pgRNA correlated with MIP-1α, HbcAg correlated with TNF-α, IL4, IL5, IL17, TGF-β1 and IP10, HBsAg and HBV DNA did not correlated with cytokines.

**Conclusions:** pgRNA and HBcAg showed more closely relationship with cytokines in HBeAg-positive pregnant CHB patients compared to traditional HBV serum markers.

IFN-α provides dual benefits of reducing HCC and facilitating HBsAg loss for NA-treated CHB patients

Shaowen Jiang1, Simin Guo1, Haiguang Xin1, Jie Xu2, Yi Li3, Yilan Zeng4, Yuan Guo5, Lijuan Ouyang6, Chuanwu Zhu7, Weifeng Zhao8, Qin Zhang9, Qing Guo1, Qing Xie1  
1Ruijin Hospital, Shanghai Jiao Tong University School of Medicine Shanghai China, 2Shanghai Ninth People's Hospital, Shanghai Jiao Tong University School of Medicine Shanghai China, 3Anhui Provincial Hospital Hefei China, 4Chengdu Public Health Clinical Medical Center Chengdu China, 5The Affiliated Hospital of Qingdao University Qingdao China, 6Xiamen Hospital of Traditional Chinese Medicine Xiamen China, 7The Affiliated Infectious Diseases Hospital of Soochow University Suzhou China, 8Xinxiang Medical University Third Hospital Xinxiang China, 9Tongren Hospital, Shanghai Jiao Tong University School of Medicine Shanghai China

**Background:** This study is to investigate whether peginterferon-α-2b (IFN) add-on Nucleos(t)ide analogs (NAs) can further reduce hepatocellular carcinoma (HCC) risk compared with NAs monotherapy in NAs-treated patients with chronic hepatitis B (CHB).

**Methods:** In this multi-center randomized controlled trial “PARADISE study” (NCT05671315), CHB patients with intermediate to high risk of HCC, who had undetectable HBV DNA after more than 24-week NAs pretreatment, were recruited, randomized to two groups at a ratio of 1:2 and followed up for 240 weeks. NAs group continued NAs monotherapy, while IFN+ NAs group received IFN add-on NAs therapy for 48 weeks, then switched to NAs monotherapy. The changes of HBV serological markers at week 48 and the 96-week cumulative incidences of HCC were compared between groups.

**Results:** A total of 196 CHB patients were included in the interim analyses based on 96-week follow-up data (68 in NAs group, 128 in IFN+NAs group). The 96-week cumulative incidence of HCC was markedly lower in IFN+NAs group than NAs group (0% vs. 4.5%, log-rank test p=0.05). Compared with NAs group, IFN+NAs group had a significantly lower level of HBsAg at week 48 (1.55±3.1884 vs. 2.885±0.714 log10 IU/ml, p<0.001) and a notably greater HBsAg decline from baseline to week 48 (1.24±1.333 vs. 0.095±0.333 log10 IU/ml, p=0.001). Rates of HBsAg loss and HBsAg seroconversion at week 48 were much higher in IFN+NAs group than NAs group (21.9% vs. 0%, p=0.001; 18.0% vs. 0%, p=0.001).

**Conclusion:** IFN add-on NAs therapy is superior to NAs monotherapy in reducing HCC risk and facilitating HBsAg loss among NA-treated virologically suppressed CHB patients with intermediate to high risk of HCC.

The Everest Project’s 5-Year Update: Efficacy of PegIFNα Therapy in NA-suppressed HBsAg negative CHB

Chan Xie1, Dongying Xie1, Qihuan Xu1, Lei Fu1, Xinyue Chen1, Jiahong Yang1, Guojun Li2, Jiabin Li2, Yilan Zeng1, Yongfang Jiang1, Wenhua Zhang3, Hong Tang4, Zhiliang Gao1  
1Third Affiliated Hospital of Sun Yat-sen University, Department of Infectious Diseases Guangzhou China, 2Xiangya Hospital Central South University Changsha China, 3Beijing Youan Hospital, Capital Medical University Beijing China, 4People's Hospital of Deyang City Deyang China, 5The People's Hospital of Shenzhen Shenzhen China, 6The First Affiliated Hospital of Anhui Medical University Hefei China, 7Chengdu Public Health Medical Center Chengdu China, 8The Second Xiangya Hospital of Central South university Changsha China, 9Gansu Wuwei Cancer Hospital Wuwei China, 10West China Hospital Sichuan University Chengdu China

**Background and Aims:** This study aims to evaluate the efficacy and safety of pegIFNα-based therapy in real-world nucleoside analog (NA)-treated chronic hepatitis B (CHB) patients and identify predictors for HBsAg loss by pegIFNα.

**Method:** The Everest Project, a multicenter real-world study in China, was previously introduced, focusing on the HBsAg loss of CHB (NCT04035837). Patients with over a year of NA therapy, HBV DNA < 100 IU/mL, HBeAg negative, and HBsAg ≤ 1500 IU/mL were recruited starting in 2018. PegIFNα-2b monotherapy or combination with NA was performed. The 5-year study enrollment has now concluded, and the latest research data is presented here.

**Results:** Out of the total 23,412 patients recruited, 15,896 were included in PP group. Of the total patients over 48-week treatment, 77.47% were male, with an average age of 41.77 years and a mean HBsAg baseline of 378.05 IU/mL. 3864 patients achieved HBsAg loss. The HBsAg loss rates...
were 10.75%, 22.72%, 28.72% and 31.43% at 12, 24, 36 and 48 weeks in PP group, respectively, higher than that in mITT group (figure 1A, B). Factors predicting higher HBsAg loss included a lower HBsAg baseline, reduced HBsAg levels at 12 and 24 weeks, ALT flare at the 12-week mark, younger age, female gender, and a lower BMI. There were no severe adverse events during this project.

**Conclusion:** HBsAg loss rate could be over 30% in NA-suppressed CHB patients with pegIFNα strategy. Baseline and on-treatment predictors can better guide the achievement of functional cure.

Abstract Submission No. 100730

**Clinical Study on the Efficacy and Safety of Interferon in Compensatory hepatitis B Cirrhosis**

Tianjing Zhang1, Xiaohong Gao2

1Yan’an University Affiliated Hospital, Yan’an China, 2Yan’an University Affiliated Hospital, Yan’an China

**BACKGROUND:** There are limited data on the efficacy and safety of polyethylene glycolated interferon-alpha 2b (PEG-IFNα2b) antiviral therapy in patients with compensated hepatitis B cirrhosis. In this study, we aimed to evaluate the efficacy of PEG-IFNα2b in HBsAg-positive patients.

**METHODS:** A total of 52 HBeAg-positive patients with compensated hepatitis B cirrhosis who had not received antiviral therapy were divided into two treatment groups: Group A (12 patients): patients were injected with Peg IFNα2b (180 μg) subcutaneously once a week; Group B (20 patients each): ETV (0.5 mg) or TDF (300 mg) was administered orally once a day for 48 weeks, and observed for 12 weeks. Group B (20 cases each). Blood samples were collected at baseline and every 12 weeks. ALT, AST, HBV DNA quantification and HBsAg, HBsAb, HBeAg, HBeAb, HBcAb levels were measured.

**RESULTS:** In group A, HBsAg levels decreased rapidly in the first 12 weeks and gradually declined over the next 36 weeks, the proportion of patients with undetectable HBV DNA was 100% during the observation period, and HBsAb increased significantly and stabilized. The rate of loss of HBsAg in group B was lower than that in group A. In group B, the rate of loss of HBsAg was lower than that in group B.

**CONCLUSION:** This real-world study demonstrated superior efficacy in HBsAg-positive patients after 48 weeks of treatment with PEG-IFNα2b alone than with oral medications. However, this study needs to be validated with larger sample size studies.

Abstract Submission No. 100754

**ChB patients with extremely low-level viremia - clinical characteristics and prognosis.**

Xiaonan Wu1,2,3,4, Qiao Zhang1,2,3,4, Yushan Liu1,2,3,4, Siyi Liu1,2,3,4, Qijuang Zhang1,2,3,4, Chengbin Zhu1,2,3,4, Yamin Wang1,2,3,4, Ye Lu2,3,4, Yingren Zhao2,3,4, Taotao Yan2,3,4, Yingli He5

University Xi’an, Shaanxi China

**Introduction:** After 48 weeks of treatment with nucleoside analogs (NAs), some chronic hepatitis B (CHB) patients can still detect HBV DNA by high-sensitivity polymerase chain reaction, but it can not be quantified accurately. This group requires further research to define their clinical characteristics and long-term prognosis.

**Method:** CHB patients received NAs treatment for over 48 weeks were divided into 4 groups based on virological response: sustained virological response group (SVR, HBV DNA undetected), extremely low-level viremia group (eLLV, HBV DNA<2000IU/ml). Analysis of baseline characteristics, long-term biochemistry, HBV markers, and disease progression was performed for each group.

**Result:** A total of 989 CHB patients were enrolled, including SVR (n=186), eLLV (n=468), LLV (n=295), and PVR (n=40). Serum ALT, the ratio of liver cirrhosis in eLLV and SVR are compared, which is different from LLV. HBsAg and the positive rate of HBeAg in eLLV were significantly lower than LLV while higher than SVR. After a median follow-up of 5 years, The incidence of hepatocellular carcinoma was observed with no difference in eLLV (9/468 1.92%) and SVR (4/186 2.15%), but it was lower than LLV (17/295 5.76%). Moreover, eLLV had a lower re-compensation rate for liver cirrhosis (27/170, 15.9%) than SVR (24/69, 34.8%), but comparable to LLV (12/76, 15.8%).

**Conclusion:** Extremely low viral load has little short-term effect on hepatitis patients’ survival. Longer follow-up is needed for prognosis. Liver cirrhosis patients with LLV and eLLV should decrease viral load for improved prognosis.

Abstract Submission No. 100771

**The incidence of renal tubular absorption dysfunction among patients with NUC plus PegIFNα2b therapy**

En-Qiang Chen1, Yu-Jing Li1, Cheng-Run Song1, Xi-Jia Luo1, Min He1, Yong-Hong Wang1, Ya-Chao Tao1, Meng-Lan Wang1, Rong Deng1, Xue-Zhong Lei1, Hong Tang1, Tao-You Zhou1, Fang He2

1West China Hospital, Sichuan university Chengdu China

**Objective:** This study aims to evaluate the occurrence of renal tubular absorption dysfunction in CHB patients during NUC+PegIFNα2b treatment.

**Method:** This study focuses on CHB patients who received NUC+PegIFNα2b treatment at West China Hospital from February 2023 to July 2023, and evaluates the incidence of elevated urine β2-microglobulin (β2-MG) and decreased blood phosphorus during the treatment.

**Result:** A total of 92 patients were included, including 76 males and 16 females, with a median age of 37.5 years. After 12 to 24 weeks of NUC+PegIFNα2b treatment, 73.9% (68/92) developed urinary β2-MG increased, with 43.5% (40/92) less than 3 times the upper limit of normal (ULN), 6.5% (6/92) between 3-5 times ULN, 6.5% (6/92) between 5-10 times ULN, and 17.4% (16/92) more than 10 times ULN. In addition, 33.7% (31/92) of patients experienced a decrease in blood phosphorus, with 27.2% (25/92) showing a decrease of less than 20% and 6.5% (6/92) showing a decrease of 20%-60%. A total of 23 patients experienced simultaneous simultaneously β2-MG increase and blood phosphorus decrease. Among patients with TAF+PegIFNα2b, 27.3% (18/66) experienced urinary β2-MG elevation>3 times ULN, and 33.3% (22/66) showed a decrease in blood phosphorus. Among patients with ETV+PegIFNα2b, 41.7% (5/12) experienced experienced urinary β2-MG elevation>3 times ULN, and 41.7% (5/12) showed a decrease in blood phosphorus.

Abstract Submission No. 10062

**The efficacy of TDF+NUC treatment in CHB patients with high HBV DNA titer**

Haiyan Zhai1,2, Yajie Wang1,2, Meng Wang1,2, Renmin Wang1,2, Yangdong Sun1,2, Yonghong Zhang1,2, Liyang Qiu1,2

1Infectious Disease, The First Hospital of Xi’an Jiaotong University, 2Clinical Research Center for Infectious Diseases, Xi’an Jiaotong University Xi’an, Shaanxi, China

**Objective:** Evaluate the efficacy of TDF+NUC treatment in CHB patients with high HBV DNA titer.

**Method:** A total of 98 CHB patients were enrolled, including 76 males and 22 females, with a median age of 37.5 years. After 12 to 24 weeks of NUC+PegIFNα2b treatment, 73.9% (68/92) developed urinary β2-MG increased, with 43.5% (40/92) less than 3 times the upper limit of normal (ULN), 6.5% (6/92) between 3-5 times ULN, 6.5% (6/92) between 5-10 times ULN, and 17.4% (16/92) more than 10 times ULN. In addition, 33.7% (31/92) of patients experienced a decrease in blood phosphorus, with 27.2% (25/92) showing a decrease of less than 20% and 6.5% (6/92) showing a decrease of 20%-60%. A total of 23 patients experienced simultaneous simultaneously β2-MG increase and blood phosphorus decrease. Among patients with TAF+PegIFNα2b, 27.3% (18/66) experienced urinary β2-MG elevation>3 times ULN, and 33.3% (22/66) showed a decrease in blood phosphorus. Among patients with ETV+PegIFNα2b, 41.7% (5/12) experienced experienced urinary β2-MG elevation>3 times ULN, and 41.7% (5/12) showed a decrease in blood phosphorus.
35.7% (5/14) experienced urinary β2-MG elevation>3 times ULN, and 28.6% (4/14) showed a decrease in blood phosphorus.  

Conclusion: The incidence of renal tubular absorption dysfunction is relatively high among patients with NUC+PegIFNα2b combination therapy.

Abstract Submission No. 100772

Efficacy of antiviral therapy in ALT normal chronic HBV infection

Lei Ma1, Yan Li2, Huichun Xing3  
186 10-84322291 Beijing China, 2Center of Liver Diseases Division 3, Beijing Ditan Hospital, Capital Medical University Beijing China, 3Center of Liver Diseases Division 3, Beijing Ditan Hospital, Capital Medical University Beijing China

Objective: This study aimed to assess virological response efficacy and predictive factors in antiviral-treated patients with normal ALT levels.

Methods: We reviewed 164 treatment-naive CHB patients receiving antiviral treatment (ETV, TDF, or TAP) at Beijing Ditan Hospital, Capital Medical University, between May and December 2020. Of these, 46 patients had normal ALT (ALT<50 U/L), and 118 had abnormal ALT (ALT>50 U/L). Baseline and 12, 24, and 48-week post-treatment clinical data were collected to compare virological indicators between groups. The ALT normal group was divided into complete and poor virological response subgroups based on the HBV DNA at week 48, and predictive factors were analyzed using binary logistic regression.

Results: The highest baseline ALT in the abnormal ALT group was 2106.7 U/L, the highest baseline value of Log HBV DNA was 9.2 LogIU/ml, with a mean Log HBV DNA value of 7.3 LogIU/ml. In the normal ALT group, the highest baseline Log HBV DNA was 8.5 LogIU/ml, with a mean value of 7.2 LogIU/ml. The difference of HBV DNA viral load at baseline between groups was not statistically significant (p=0.183). After 48 weeks antiviral treatment, the mean Log HBV DNA values decreased to 1.4 LogIU/ml for ALT abnormal and 1.7 LogIU/ml for ALT normal, with no statistically significant difference (p=0.062). Virological response (HBV DNA<20 IU/mL) rates in the ALT abnormal group was 62.7% (74/118), compared to 43.5% (20/46) in the ALT normal group, showing statistical significance (p=0.025). No significant differences were observed at 12 and 24 weeks (p=0.056, 0.991). HBeAg serologic conversion rates after 48 weeks were 8.5% in the ALT abnormal group and 17.4% in the ALT normal group, showing statistical significance (p=0.183). After NUCs treatment, the ALT normal group was divided into complete and poor virological response subgroups based on the HBV DNA at week 48, and predictive factors were analyzed using binary logistic regression.

Conclusion: At week 48 post-antiviral treatment, the ALT normal group exhibited a lower virological response rate than the ALT abnormal group. High HBSAg and HBeAg positivity were predictive factors for poor virological response in the ALT normal group. Larger studies are needed to validate these findings due to the small sample size.

Liver volume re-compensation in HBV-related decompensated cirrhosis after NUCs therapy

Qijuan Zang1, Siyi Liu2, Juan Li3, Chengbin Zhu4, Qiao Zhang5, Yushan Liu6, Xiaonan Wu7, Yamin Wang8, Qiannan Wang1, Pan Huang1, Li Zhu9, Yingren Zhao10, Yingli He11  
1Department of Infectious Diseases, the First Affiliated Hospital of Xi’an Jiaotong University, Xi’an, Shaanxi, China. Xi’an China, 2Institution of Hepatology, The First Affiliated Hospital of Xi’an Jiaotong University, Xi’an, Shaanxi, China. Xi’an China, 3Shaanxi Clinical Research Center for Infectious Diseases, Xi’an, Shaanxi, China. Xi’an China, 4Clinical Research Center for Infectious Diseases, The First Affiliated Hospital of Xi’an Jiaotong University, Xi’an, Shaanxi, China. Xi’an China

Background: NUCs therapy can effectively inhibit HBV replication and enhance the long-term prognosis of individuals with HBV-related decompensation, and some patients can achieve re-compensation. Liver volume serves as a crucial measure for assessing liver reserve function, the precise impact of liver volume on re-compensation remains uncertain.

Methods: We retrospectively included 159 HBV-related decompensated patients who received NUCs treatment. All patients underwent two abdominal CT scans. Software was utilized to measure the actual liver volume (LV), while the standard liver volume (ELV) was calculated by thoracic width. The liver volume ratio (LV/ELV%) was employed to eliminate individual differences. The changes of liver volume were dynamically observed during follow-up.

Results: The cumulative re-compensation rate over a period of two years was 37.7%. Prealbumin was linearly positively correlated with LV/ELV% (r = 0.515, P < 0.001), while prothrombin time was negatively correlated with LV/ELV% (r = -0.411, P < 0.001). After NUCs treatment, LV (979.13 ±256.42 cm³ vs 1081.72 ±273.67 cm³, P < 0.05) and LV/ELV% of HBV-related decompensated patients increased, while LV (985.02 ±247.78 vs883.38 ±261.91 cm³, P < 0.01)
and LV/ELV% decreased in the persistent decompensated group. The risk of death was significantly increased in patients with LV < 950cm³ and LV/ELV% < 80%. The 5-year survival rate was significantly improved in patients with LV > 1000cm³ and LV/ELV% > 80%.

Conclusion: Patients with HBV-related decompensation can reverse liver fibrosis and enhance liver regeneration after receiving effectively NUCs treatment. Liver volume re-compensation is beneficial to long-term functional re-compensation.

Abstract Submission No. 100886

Higher risk of disease progression in the grey zone relative to inactive Chronic hepatitis B

Yunling Xue1,2, Guorui Wang1,2, Xiaoqing Liu1,2, Qiao Tang1,2, Jingsong Wang3, Jing Zhang1,2, Mingli Peng9, Peng Hu1,2
1Chongqing Medical University Chongqing China, 2Institute for Viral Hepatitis, Chongqing Medical University, Chongqing, China

Abstract:
Background & aims: Chronic hepatitis B (CHB) remains a global healthcare burden. Inactive CHB (IC) is the commonest immune state. There are also patients with normal alanine aminotransferase (ALT) and HBeAg negative, which guidelines refer to as the IC corresponding grey zone (GZIC). There is still confusion about the evolution of disease progression in the GZIC. So we aimed to study the natural history of IC and GZIC.

Method: This was a retrospective-prospective cohort study that included 300 patients with stage IC and GZIC. Conversion to HBeAg-negative immune-active CHB (IA) and IA corresponding grey zone (GZIA), initiation of antiviral therapy, and occurrence of end-stage liver disease events were defined as outcome events. The cumulative incidence of outcome events in the IC and GZIC groups was compared.

Results: At baseline, 201 (67.00%) patients were IC and 99 (33.00%) were GZIC. 18.9% of the 300 patients with IC and 46.4% of the patients with GZIC converted to IA or GZIA. 30 (10%) received antiviral therapy, of which 22 (77.3%) were patients with GZIC and 8 (22.7%) were IC patients. Nine (3%) developed end-stage liver disease of which seven (77.8%) were GZIC and two (22.2%) were IC. The cumulative event rates for conversion to IA or GZIA, initiation of antiviral therapy, and occurrence of end-stage liver events were higher in GZIC than in IC (p <0.0001, p <0.0001, p =0.0018) (Figure 1).

Conclusion: Patients with GZIC have a higher risk of disease progression than those with IC.

Antiviral effect in patients with chronic hepatitis B infection in the indeterminate phase

Mingyang Feng1, Xiaoyin Wang1, Xuehui Liu1, Gangde Zhao1, Baoyan An1, Lanyi Lin1, Yezhou Ding1, Qing Xie1, Hui Wang1
1Department of Infectious Diseases, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine Shanghai China

Background: Emerging data suggest that a substantial proportion of patients with chronic hepatitis B (CHB) do not fall into any of the defined phases and are considered indeterminate. These CHB patients have a significantly high risk of hepatocellular carcinoma. Little is known about the effect of antiviral therapy for these patients. We aimed to investigate liver histology and assess the effect of antiviral treatment on these patients.

Methods: We retrospectively analyzed the outcomes of antiviral therapy for CHB patients in the indeterminate phase who underwent liver biopsy and were treated with nucleoside/nucleotide analogues (NAs) or polyethylene glycol interferon (PEG-IFN) for up to 96 weeks.

Results: A total of 241 patients receiving NAs (n = 206) or PEG-IFN (n = 17) or NAs + PEG-IFN (n = 18) were included, 18.7% (45 of 241) were HBeAg positive. Approximately 80% of CHB patients in the indeterminate phase had significant histological changes. At week 96, the rate of undetectable HBV DNA in NAs group, PEG-IFN group or NAs + PEG-IFN group was ~99.0%, ~88.2% or ~100.0%, respectively. No patients were found to have viral resistance to therapy. In NAs group, HBeAg clearance rate were 10% (4 of 40) at week 48. No patient had loss of hepatitis B surface antigen.

Conclusion: Majority of CHB patients in the indeterminate phase had significant liver histological changes. Antiviral therapy can effectively inhibit HBV replication in these CHB patients, although rates of HBeAg seroconversion and hepatitis B surface antigen loss were low.

NAFLD comorbidity predicts higher ALT and liver stiffness: A longitudinal study in CHB patients

YAN Huang1, Bingyin Du1, Shuyin Song1, Rongtao Lai1, Qing Xie1
1Shanghai Jiaotong University, School of Medicine, Ruijin hospital Shanghai China

Introduction: The impact of NAFLD in chronic hepatitis B virus (HBV) infection remains further exploration.

Methods: We enrolled 784 treatment-naïve HBV-infected patients who underwent liver biopsies. The presence of steatohepatitis was evaluated according to the NAFLD activity score (NAS). After the liver biopsy, biochemical measures and liver stiffness (LS) measurements were performed repeatedly. Mixed models were used to evaluate the associations of steatosis (NAS score 1-2) or steatohepatitis (NAS score 3-8) with longitudinal ALT, FIB-4 and LS.

Results: Among 784 patients without excessive alcohol intake, 174 (22.2%) had steatosis only and 110 (14.0%) had steatohepatitis. Steatohepatitis (versus no FLD) was associated with 1.90 times higher ALT (versus no FLD) was associated with 1.90 times higher risk of advanced fibrosis at baseline (95%CI, 1.10-3.28) and also associated with 1.20 times higher ALT (P<0.001), 1.11 times more frequent ALT elevation (P<0.001), 1.17 times higher FIB-4 (P=0.0021) and 2.20 times higher liver stiffness (P=0.0044) across eight years follow-up. Although steatosis (versus no FLD) has no association with a higher risk of advanced fibrosis at baseline and higher FIB-4 (both P>0.05) across follow-up, steatosis was associated with 1.16 times higher ALT (P<0.001), 1.08 times more frequent ALT elevation (P<0.001) and 1.70 times higher liver stiffness (P=0.017) during the follow-up period. Similar results were found in the subgroup who received antiviral treatment within 6 months after liver biopsy.

DISCUSSION: The presence of NAFLD was associated with higher hepatic inflammation and fibrosis over time, whether antiviral treatment started or not. Therefore, besides viral suppression, prevention of the progression of fatty liver is also crucial in HBV.

Elevated Risk of in clinical outcomes Untreated HBeAg-Positive CHB Patients in Indeterminate Phase

Vicki Wing-Ki Hui1, Grace Lai-Hung Wong1, Yee-Kit Tse1, Jimmy Che-To Lai1, Vincent Wai-Sun Wong1, Terry Cheuk-Fung Yip1

11Department of Medicine and Therapeutics, Medical Data Analytics Centre (MDAC), Institute of Digestive Disease Hong Kong Hong Kong

Background: The indeterminate phase of HBeAg-positive chronic hepatitis B (CHB) has not been covered by antiviral therapy in the current management guidelines. This study assessed hepatocellular carcinoma (HCC) and cirrhotic complication risks of these patients.

Methods: This was a territory-wide cohort study of untreated non-cirrhotic hepatitis B e antigen (HBeAg)-positive CHB patients with identifiable CHB phases based on their serial alanine aminotransferase (ALT) and hepatitis B virus (HBV) DNA. Patients with HBeAg-positive indeterminate phase were further classified into either the high HBV DNA group with a load of 20,000 to 1,000,000 IU/mL and normal ALT (i.e., high HBV DNA) or the low HBV DNA group with a load <20,000 IU/mL and elevated ALT (i.e., low HBV DNA).

Results: Among 11,288 patients, 54.7% were male with a mean age of 43.7 ± 13.8 years. 3,107 patients (27.5%) were in the indeterminate phase, with 78% in the high HBV DNA group. At a median follow-up of 6.2 [3.6, 9.6] months, 2,441 (78.6%) remained indeterminate. In the HBeAg-positive indeterminate phase, the high HBV DNA group showed a 10-year cumulative incidence of 6.7% vs. 4.2% (P < 0.001) and cirrhotic complications of 13.2% vs. 8.8% (P < 0.001) when compared to the low HBV DNA group.

Conclusions: HBeAg-positive indeterminate phase patients with high HBV DNA levels face significantly increased 10-year risks of HCC and cirrhotic complications. Further studies are vital to evaluate the benefits of early antiviral treatments.

Prolonged indeterminate phase in untreated chronic hepatitis B-infected patients

Vicki Wing-Ki Hui1, Grace Lai-Hung Wong1, Yee-Kit Tse1, Jimmy Che-to Lai1, Vincent wai-sun Wong1, Terry cheuk-fung Yip1

11Department of Medicine and Therapeutics, Medical Data Analytics Centre (MDAC), Institute of Digestive Disease Hong Kong Hong Kong

Background: Indeterminate phase of chronic hepatitis B (CHB) has not been covered by antiviral therapy according to the current management guidelines. We aimed to determine the transition dynamics of the indeterminate phase.

Methods: This was a territory-wide cohort study of untreated non-cirrhotic CHB patients with identifiable CHB phases based on their serial alanine aminotransferase (ALT) and HBV DNA. Indeterminate phase was defined according to the European Association for the Study of the Liver guidelines. Follow-ups were censored at the earliest event among antiviral treatment initiation, last follow-up, December 2022, or death.

Results: Of 42,837 patients, 22,166 (51.74%) were in the indeterminate phase at study entry; 6,256 (14%) of them were HBeAg-positive, with a mean age of 51.8 ± 13.9, and 56.5% were male. At a median follow-up of 11.5 [1.0, 50.2] months, 15,367 (69%) remained indeterminate, while 3,573 (16.1%) and 3,226 (15%) transitioned to immune clearance and immune active phases, respectively. For the HBeAg-positive indeterminate group, 78% stayed in the indeterminate phase at the last follow-up, with most of the rest transitioning to immune active phase, 67% of the HBeAg-negative indeterminate group remained indeterminate, with 0.13% and 18.15% transitioned to immune clearance and immune active phases respectively.

Conclusions: Most patients continue to remain in indeterminate phase over time, suggesting that this phase in CHB patients is not transient. The indeterminate phase warrants closer clinical attention, including evaluating the risks associated with clinical outcomes, specifically hepatocellular carcinoma and cirrhotic complications, in this patient population.

Abstract Submission No. 100960

Long-term effects of tenofovir and entecavir cessation in HBeAg negative chronic hepatitis B

Onuma Sattayalertanyong1, Wimalrak Bandidnianamanon1, Julakaj Limsrivilai2, Watcharasak Chotiyaputta1, Supot Nimanong1, Tawesak Tanwandee1

11Division of Gastroenterology, Department of Medicine, Faculty of Medicine Siriraj Hospital, Mahidol University Bangkok Thailand

Background: Recent studies found that nucleos(t)ide analogues (NA) stopping will lead to more rapid HBsAg clearance and safe. However, few studies reported the long-term outcomes after the discontinuation. This study aim to evaluate HBsAg loss, virological relapse (VR), clinical relapse (CR), and safety after cessation of tenofovir (TDF) or entecavir (ETV).

Methods: A total of 98 non-cirrhotic HBeAg negative chronic hepatitis B patients (CHB), treated with either TDF or ETV for at least three years and virally suppressed were enrolled into TDF discontinued (TDF-D, n = 39), ETV discontinued (ETV-D, n = 27) groups compared continued group (continue, n = 32). All patients were followed for at least one year and up to 4 years after NA discontinuation.

Results: The median follow-up time was 146 weeks, and seven patients (10.6%) achieved HBsAg clearance after NA discontinuation. All of them had end-of-treatment (EOT) HBsAg levels <100 IU/ml. Cumulative incidences of VR and CR at week 48, 96 and 144 in both TDF-D, ETV-D were shown in Fig1A,B,C. The cumulative rate of HBsAg loss, VR, and CR in patients with EOT-HBsAg <100 IU/ml and ≥100 IU/ml were shown in Fig1D,E,F. EOT-HBsAg level was a significant predictor for HBsAg clearance (HR = 0.21, 95% CI 0.05–0.89, P = 0.028). Six patients in TDF-D had severe ALT flares, two required admission, and one death.

Conclusions: NA cessation led to achieving HBsAg clearance more than NA continuation and usually in the first year; however, it increased risk of VR and CR, especially TDF group, and patients with high EOT-HBsAg levels. Some resulted in early and more severe CR, which lead to hepatic decompensation and death.
Introduction and objectives: Entecavir (ETV) is a preferred antiviral for chronic hepatitis B (CHB). However, its impact on renal function in patients with CHB remains inconclusive in the literatures. The aim of this study was to comprehensively assess the impact of ETV treatment on both glomerular and tubular function in patients with CHB and to investigate the potential role of renal impairment associated with long-term ETV therapy.

Patients and methods: A total of 602 CHB patients were enrolled in this study. Propensity score matching (PSM) was utilized to balance confounding factors. Comparative analyses were performed between the ETV treatment group and non-antiviral treatment CHB group, the ETV treatment group and the tenofovir alafenamide (TAF) treatment group, as well as the ETV treatment group with more than 5 years of treatment (8.68±3.43 years) and the ETV treatment group with less than 5 years of treatment (2.31±1.22 years). Renal function indicators measured included eGFR, urinary albumin-to-creatinine ratio, urinary retinol-binding protein, urinary β2-microglobulin, urinary α1-microglobulin, serum phosphate, and serum cystatin C.

Results: After propensity score matching, no significant differences were observed in renal function indicators between the ETV treatment group and the non-antiviral treatment group (P > 0.05), between the ETV treatment group and the TAF treatment group (P > 0.05), and between the ETV treatment group with more than 5 years of treatment and the ETV treatment group with less than 5 years of treatment (P > 0.05).

Conclusions: Long-term ETV treatment shows no evident renal impairment.

Study on replication-competent HBV DNA in hepatitis B cirrhosis with HCC patients

Baiguo Xu1,2,3, Jia Lian1,2,3, Jing Liang1,2,3, Huiling Xiang1,2,3, Qing Ye4, Lei Liu1,2,3

1The Third Central Clinical College of Tianjin Medical University, Tianjin, China tianjin china, 2The Third Central Hospital of Tianjin Tianjin China, 3Tianjin Institute of Hepatobiliary Disease tianjin China

Background: The purpose of this study was to determine the level of replication-competent HBV DNA A in liver tissue to investigate its role in decompensation events and recompensation in patients with hepatitis B cirrhosis complicated with primary liver cancer.

Methods: The level of replication-competent HBV DNA was detected by droplet digital PCR assay (ddPCR) method with mono-over-gap rcDNA primers. The value of replication-competent HBV DNA levels with a difference between the two groups (P=0.042). In the follow-up of 16 patients with decompensated hepatitis B cirrhosis complicated with primary liver cancer, the median and interquartile distance of replication-competent HBV DNA in patients with and without decompensation were 3.50 (3.23-3.96) and 4.25 (4.04-4.45), respectively, and there was a difference between the two groups (P=0.026).

Conclusion: In patients with hepatitis B cirrhosis complicated with primary liver cancer, the level of HBV DNA replication in liver tissue is higher in patients with decompensated events. The level of HBV DNA replicating universal in liver tissue was lower in patients with recompensation.

Multi-parametric MRI identified chronic hepatitis B patients with subclinical liver inflammation

Irdina s Nadziruddin1, Yu Jun Wong2,3, John j Connell4, Elizabeth Shumbayawonda1, Andrea Dennis1, Rajarshi Banerjee5, Marianne Anastasia De Roza4, Ngiap Chuan Tan4, Han Chong Toh4, Jason Pik Eu Chang5, Guan Huei Lee6, Wei Lyn Yang7, Sir Michael Brady1, Pierce Chow1,8, Study Investigators AHCIC10

1Perspectum Ltd Oxford United Kingdom, 2Department of Gastroenterology & Hepatology, Changi General Hospital Singapore Singapore, 3Duke-NUS Medical School Singapore Singapore, 4Department of Gastroenterology and Hepatology, Sengkang General Hospital Singapore Singapore, 5SingHealth Polyclinic - Pasir Ris Singapore Singapore, 6National Cancer Centre Singapore Singapore Singapore, 7Department of Gastroenterology and Hepatology Singapore Singapore, 8Division of Gastroenterology & Hepatology, Department of Medicine, National University Hospital Singapore Singapore, 9Gastroenterology and Hepatology, Tan Tock Seng Hospital Singapore Singapore, 10Asia Pacific Hepatocellular Carcinoma Trials Group Singapore Singapore

Background: Chronic hepatitis B (CHB) patients with ongoing necroinflammation have elevated risk of cirrhosis and hepatocellular carcinoma (HCC). Alanine transaminase (ALT), a key serum biomarker recommended by all clinical guidelines, is used to stratify patients for antiviral therapy or cirrhosis surveillance but is often inaccurate due to the heterogeneous nature of hepatitis B virus (HBV) infections. Liver biopsy, the current reference standard, has significant well reported limitations. Iron-corrected T1 (cT1), a multi-parametric MRI (mpMRI) biomarker, correlates well with liver disease including inflammation and fibrosis, and can predict liver related outcomes. Our aim was to evaluate the utility of cT1 to identify subclinically active disease in non-cirrhotic CHB patients in biochemical remission.

Methods: This nested-cohort study within the ELEGANCE cohort (prospective multi-centre study enrolling patients at increased risk of HCC in Singapore, NCT04965259) included 77 non-cirrhotic CHB patients with paired mpMRI (LiverMultiScan®) and ALT scores. On-going inflammation and active disease was defined as cT1>800ms. Normal ALT was defined as ≤25U/L.

Results: ALT and cT1 were positively correlated (r=0.32, p=0.004). Although the majority with ALT≤25U/L had low cT1 (<800ms), 8% with normal ALT had active disease with cT1>ULN (829ms [813ms-880ms]). ALT was suboptimal at ruling-out CHB patients with ongoing liver inflammation. (sensitivity: 42.9%, specificity: 65.7%, NPV: 92.0%, PPV: 11.1%).

Conclusion: ALT levels, while commonly used for monitoring CHB patients, will miss 8% of CHB patients with subclinically active disease. cT1 using mpMRI can identify ongoing liver inflammation which in turn prevents long-term liver-related complications.

The effect of tenofovir amibufenamide on lipid metabolism

En-Qiang Chen1, Lan-Qing Li1, Cheng-Run Song1, Yu-Jing Li1, Xue-Zhong Lei1, Hong Tang1, Dong-Mei Zhang1, Yong-Hong Wang1, Tao-You Zhou1
Objective: To analyze the effect of tenofovir alafenamide (TMF) on blood lipid metabolism in CHB patients

Method: CHB patients treated with TMF monotherapy for more than 1 year were screened, and the blood lipid metabolism related indicators were quantitative tested before and after TMF treatment.

Result: A total of 109 patients with complete demographic and clinical follow-up data were included, and their peripheral blood cholesterol, triglycerides, high-density lipoprotein (HDL), very low-density lipoprotein (VLDL) and ApoB levels were within the normal range before receiving TMF treatment. After more than 1 year of TMF treatment, 28.4% (31/109) of patients had triglyceride levels exceeding the upper limit of normal (ULN), with 67.7% (21/31) of patients having an increase of no more than 30% of ULN; 15.6% (17/109) of patients had total cholesterol levels exceeding the ULN, with 52.6% (9/17) of patients having an increase of no more than 30% of ULN; 11% (12/109) of patients had VLDL levels exceeding the ULN, with 66.6% (8/12) of patients having an increase of no more than 30% of ULN. In this group of cases, in this group of cases, 14.7% (16/109) of patients had HDL levels exceeding the ULN. There was no significant difference in the average level of ApoB between before and after TMF treatment, but approximately 11% (12/109) of patients had peripheral blood ApoB slightly exceeding the ULN after 1 year of TMF treatment.

Conclusion: Patients treated with TMF can experience slight abnormalities in some blood lipid indicators, but the clinical significance is not yet clear.

Abstract Submission No. 101045

Diagnostic accuracy of FAST score, NFS, FibroScan, and FIB-4 in CHB patients with NAFLD

youwen tan1, Xinyue Zhang1, cong he1

1The Third Hospital of Zhenjiang Affiliated Jiangsu University, Zhenjiang China

Objective: To evaluate the diagnostic value of the FibroScan-AST (FAST) score, non-alcoholic fatty liver fibrosis score (NFS), FibroScan, and liver fibrosis index (FIB-4) for identifying fibrotic non-alcoholic steatohepatitis (NASH) in patients with chronic hepatitis B (CHB) with non-alcoholic fatty liver disease (NAFLD).

Methods: All patients with CHB and NAFLD who underwent liver biopsy.

Results: A total of 156 patients with CHB combined with NAFLD were included, including 69 with NASH and fibrosis stage 2 or higher (NASH+F2), and 16 with NASH and cirrhosis (NASH+F4). The AUC of FAST, NFS, liver stiffness measurement (LSM), and FIB-4 for diagnosing NASH+F2 was 0.739 (P<0.001), 0.643 (P=0.006), 0.754 (P<0.001), and 0.665 (P=0.003), respectively. The specificity of FAST, NFS, LSM, and FIB-4 was 67%, 51.8%, 78.6% and 76.8%, respectively, and the sensitivity was 75%, 78.6%, 67.9%, and 53.6%, respectively. No significant differences were found between groups. The AUC of FAST, NFS, LSM, and FIB-4 for diagnosing NASH+F4 was 0.650 (P=0.038), 0.725 (P=0.001), 0.851 (P<0.001), and 0.560 (P=0.533), respectively. The specificity of the FAST, NFS, LSM, and FIB-4 was 55.9%, 50.0%, 71.6%, and 75.5%, respectively and the sensitivity was 80.0%, 100%, 100%, and 50.0%, respectively. The differences between AUCs of FIB-4 and FAST compared with LSM were 0.291 and 0.201, respectively (P<0.05).

Conclusion: In patients with CHB combined with NAFLD, FAST did not have better accuracy than NFS and FIB-4 for predicting fibrotic NASH, whereas LSM had better accuracy than FAST and FIB-4.

Characterization of genotypes, subtypes and prevalence of occult HBV in chronic liverdisease and HCC

Hasmik Ghazinyan1, Tatevik Shahinyan2, Saro Khemichyan3, Pascal Pineau4, Tigran Aghabekyan5

1Yerevam MSC Yerevan Armenia, 2Ecosense LLC Yerevan Armenia, 3Keck Medicine of USC LA USA, 4Institut Pasteur Paris France, 5Yerevan State Medical University Yerevan Armenia

Introduction: The specific genotypes and subtypes of the hepatitis B virus (HBV) have various biological and epidemiological behaviors. The aims of the study were to understand the distribution of HBV genotypes among patients with chronic liver disease (liver cirrhosis) and hepatocellular carcinoma in Armenian patient population, as well as to investigate the possible association of HBV genotypes with different clinical outcomes.

Methods: We used the 3rd generation polymerase chain reactions technique, droplet digital PCR (ddPCR), to identify the presence of occult HBV virus infection in the plasma of patients, as well as to identify the subtype belonging of the virus. The study included 91 cases of liver cirrhosis and 69 cases of hepatocellular carcinoma.

Results: Our study on 69 HCC cases and 91 cases of non-tumor chronic liver disease (CLD) revealed that 18.8% of HCC patients very positive for HBV (in contrast to 4.4% in CLD population). Furthermore, 46.6% of HCC patients very documented to have an occult HBV infection, as opposed to 24.1% of the CLD cases. The majority of HBV cases constituted the D subtype.

Engagement in care, not antiviral therapy for all, is important to reduce early mortality from HBV

David Wong1

1University Health Network, University of Toronto Toronto Canada

Background: Liver clinic established 1979, DW 2003 to present. Free healthcare includes: clinic visits, blood tests, imaging, elastography. Paper records (1979-2006) were migrated to Epic EMR (developed by DW). On June 4, 2022, all patient records were manually migrated to Epic EMR by DW. Summary analyses obtained from Slicer Dicer module within Epic. ALT and platelet counts from Jan 2010 to present were graphed and recorded in each patient chart.

Philosophy of care: 1. HBV is not complicated 2. Not everyone needs treatment 3. Stopping treatment might be beneficial.

Results: N=2,840 individual patient records were migrated to Epic from June 4, 2022 to October 28, 2023. N=1,306 (46%) had diagnoses related to chronic HBV infection. Compared to those without chronic HBV, those with HBV were less likely to have ALD (0.6% vs 14.6%), MASLD (7.5% vs 27.7%), cirrhosis (12.2% vs 30.2%), HCC (5.5% vs 8.0%) or death (1.4% vs 4.7%). Majority (53.7%) were not on antiviral therapy. Trends over time: smaller proportion of Chinese origin and HBeAg pos HBV (now 8.1%). HCC size at diagnosis was larger in those referred to clinic for HBV/HCC compared to those with HCC discovered while being followed in clinic. Of 18 deaths, only 5 died from liver-related causes. Of those followed in clinic, only 1 died from liver. He was 83, HCC first diagnosed in 2004, had multiple recurrences, death from HCC in 2023.

Conclusion: Patients with chronic HBV infection do very well when followed in clinic, even when not on antiviral therapy.

Abstract Submission No. 101094
O-0179
Conclusion: HBV isolates subtype variants correspond to the overall distribution of genotypes in this part of Eurasia, however are more prevalent than expected, especially as occult infections. Overall, circulating mutations in plasma are promising tools for diagnosis and monitoring treatment. We aim to conduct a complementary study, add on our previously found data, and specify genomic alterations to characterize them and establish relationships between the frequency of these alterations and HCC-related mortality.

Non-invasive MRE Assessment of Liver Injury in HBeAg-negative Patient with CHB: a Case Report

Haoyao Wang1, Hailong Zhang1, Song Liu1, Guiyang Wang2, Bing Zhang1, Jie Li3, Jun Chen8

1Department of Radiology, Drum Tower Hospital, Nanjing University Medical School Nanjing China, 2Department of Infectious Diseases, Nanjing Drum Tower Hospital, Affiliated Hospital of Medical School, Nanjing University Nanjing China, 3Department of Radiology, Mayo Clinic Rochester MN USA

Background and Aims: Current guidelines recommend liver biopsy in HBsAg-negative cases with normal ALT and hepatitis B virus (HBV) DNA >2000 IU/ml; however, patients at this stage typically are not willing to accept it due to its invasive nature. We reported a 59-year-old female with HBsAg-negative chronic hepatitis B virus (CHB) who visited us for CHB management; liver injury was a concern. Six months prior to this visit, the patient underwent a liver biopsy due to the concern of liver injury in another hospital where MRE was not available, and the histopathology showed G1S0. The patient never received any anti-viral treatment.

Methods: In this visit, the patient underwent a serum blood test, HBV DNA quantification, and MRE for liver injury evaluation. FIB-4 index was calculated based on the formula: FIB-4 = age [years]×AST [IU/L]/(platelets [10^9/L]×ALT [IU/L]/2).

Results: The serum HBV DNA level is high (6.52×10^3 IU/ml) and alanine aminotransferase (ALT) is normal (18 U/L). The mean liver stiffness measured by MRE is 1.97 kPa which indicates fibrosis stage 0. The FIB-4 index is 1.31. FIB > 1.28 indicates significant fibrosis with a positive predictive value of 41.4%.

Discussions and Conclusions: In HBsAg-negative patients with normal ALTs and high HBV DNA levels, it is important to evaluate liver injury for HBV management. FIB-4 shows lower sensitivity and specificity. As the most accurate noninvasive liver fibrosis diagnosis method recommended by AGA, ACR, AASLD and AAD, MRE can be used to follow up patients requiring liver injury assessment for HBV management.

Background and Aims: We aimed to define gender-specific, optimal alanine aminotransferase (ALT) cut-off values for the prediction of significant liver histological changes (SLHC) in grey zone (GZ) chronic hepatitis B (CHB) patients with normal ALT.

Methods: This retrospective study included 1101 consecutive GZ CHB patients with normal ALT assigned to training or internal validation cohorts. An independent cohort of 842 GZ CHB patients was included for external validation. Receiver operating characteristic (ROC) curve, smoothed curve fitting, and threshold effect analyses were performed to determine the optimal ALT cut-off values, and area under the curve (AUC) values were calculated to assess their predictive performance.

Results: SLHC was observed in 79.3% of GZ CHB patients with normal ALT (≤40 U/L). ROC curve analysis initially identified optimal ALT cut-off values of 29 U/L (male) and 22 U/L (female). After smoothed curve fitting and threshold effect analyses, the new optimal cut-off values for ALT were 27 U/L for males and 24 U/L for females. Notably, the AUCs for these values reached 0.836 (male) and 0.833 (female) in the internal validation cohort and 0.849 (male) and 0.844 (female) in the external validation cohort. Moreover, the accuracy and discriminative ability of the newly defined ALT cut-off values were greater than those of the current recommendations.

Conclusion: This study established novel optimal ALT cut-off values for more precise prediction of SLHC among GZ CHB patients with normal ALT levels. As such, the findings may help identify individuals in this patient population who will benefit from timely antiviral therapy.

The negative relationship between HBV DNA and liver damage loss before HBeAg clearance in CHB

Lu fengmin1, Wang leijie1,2, Li jie3, Wang jian3, Zhao kunyu4, Jiang lina4, Zhang xinxin5, Zhao jingming4

1Department of Microbiology & Infectious Disease Center, School of Basic Medical Sciences, Peking University beijing China, 2Department of Microbiology and Immunology, College of Basic Medical Sciences, Zhengzhou University, Zhengzhou, China, 3Department of Infectious Diseases, Nanjing Drum Tower Hospital, Affiliated Hospital of Medical School Nanjing China, 4Department of Pathology and Hepatology, The Fifth Medical Center of PLA General Hospital beijing China, 5Department of Infectious Diseases, Rui Jin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai China

Background and Aims: The disease progression of chronic hepatitis B virus (HBV) infection is driven by the interactions between HBV, hepatocytes and the host immune. The dynamic changes in the
relationship between HBV replication and host immunity during disease progression need to be clarified.

**Method:** Two cross-sectional and one validation clinical cohort were recruited, and meta-analyses of cross-sectional cohorts were performed to explore the relationship between HBV replication and the severity of liver immunopathological inflammation. Gene expression profiling of liver biopsies in GSE84044 was used to explore the relationship between expression immune related gene and HBV DNA levels.

**Result:** A positive correlation between HBV replication and the severity of hepatic immunopathological inflammation was observed in HBeAg-negative patients but not in HBeAg-positive patients in each of the two cross-sectional cohorts, and this correlation was confirmed by meta-analysis. Further stratified analysis in these HBeAg-positive patients revealed distinct relationship patterns between serum HBV DNA levels and patients with relatively higher HBV DNA (≥2×10^6 IU/mL) and confirmed that in one validation cohort. Serum HBV DNA levels also correlated negatively with expression of immune-related genes, which was converted to a positive relationship in HBeAg-positive patients with relatively lower HBV DNA levels and in HBeAg-negative patients.

**Conclusion:** This study suggests that in patients with chronic HBV infection, a negative relationship between the serum HBV DNA level and liver injury, might already transformed to positive before HBeAg loss in HBeAg-positive patients with HBV DNA levels below 2×10^6 IU/mL.

**A validation study of FAL-1 score for predicting HCC risk in CHB patients treated with NAs**

Jun Inoue1, Shinichiro Minami2, Kazumichi Abe3, Mami Kida4, Hiroaki Haga5, Chikara Iino6, Hidekatsu Kuroda7, Masashi Ninomiya1, Akitoshi Sano1, Mio Iszuoka1, Atsushi Masamune1

1Department of Gastroenterology, Tohoku University Hospital Sendai Japan, 2Akita University Akita Japan, 3Fukushima Medical University Fukushima Japan, 4Kurilrara Central Hospital Kurirara Japan, 5Yamagata University Yamagata Japan, 6Hirosaki University Hirosaki Japan, 7Iwate Medical University Yahaba Japan

**Backgrounds:** Assessing the risk of hepatocellular carcinoma (HCC) in chronic hepatitis B (CHB) patients who are treated with nucleos(t)ide analogs (NAs) is clinically important. The aim of this study is to evaluate the utility of a previously reported FAL-1 score for stratifying HCC risk in NA-treated patients.

**Methods:** Clinical data of 303 NA-treated CHB patients from 6 hospitals were collected. After excluding patients with incomplete data, patients with a history of HCC, patients who developed HCC within one year of starting NA, and patients who were superheavy drinkers, 212 patients (male/female: 135/77, median age: 58.5, median follow-up: 7 years) were retrospectively analyzed.

**Results:** The median levels of T-bil, AST, ALT, PLT, and HBV DNA were 0.8 mg/dl, 38 U/L, 44 U/L, and 175,000/U/L, respectively. The HBeAg positivity rate was 20.7%. 267/51 patients were infected with HBV genotype A/B/C. 15/137/24/34 patients were treated with LAM/ETV/TDF/TAF as a first-line NA. The cumulative HCC incidences for 5 years were 0.8% (1/125) for score 0 (>1; FIB-4 ≤ 1.58: +1), the cumulative HCC incidences for 5 years were 0.2/2/13.7% for score 0 (n=76)/score 1 (n=106)/score 2 (n=25) (P=0.021). Notably, there was no HCC development in patients with score 0, consistent with the derivation cohort.

**Conclusion:** This study validated the usefulness of a simple FAL-1 score calculated from FIB-4 index and ALT at 1 year of NA.

**Reactivation of HBV in Patients With Resolved HBV Infection After Receiving DAA Treatment for HCV.**

Riaz Channa1, Nazish Butt1, Mohammed Masood1, Aman Ullah2

1Jinnah Postgraduate medical Centre. KARACHI Pakistan, 2Civil Hospital Karachi KARACHI Pakistan

**Background and Aims:** to study the risk of HBV infection reactivation while treating with direct anti-viral therapy.

**Patients And Methods:** This study was carried out on 80 patients with chronic Hepatitis C infection who were candidates for treatment with direct-acting antiviral therapy. The patients identified to carry HbsAg at baseline or with positive Hbc Antibodies were further assessed for other HBV markers: hepatitis B c antigen and serum HBV DNA quantitative measurement at baseline, at week four of starting treatment, and at the end of treatment. All patients ≥18 years of age and gender with Chronic HCV infection with inactive HBV or resolved infection were included in the study. Patients were followed for every 4-week interval for 24 weeks.

**Results:** Of our study participants, the majority were males 51 (63.7%), and females 29 (36.2%) with a mean age of 48 ± 9.5 years. At the beginning of the study, there were 32 (40%) patients who were co-infected with HCV and HBV with HBeAg + quantitative PCR for HBV DNA ≤ 20 IU/ml. 23 (29%) patients with Inactive carriers and 24 (31%) patients with resolved HBV infection. After DAAs therapy, reactivation of HBV infection was detected in 5 cases of resolved HBV infection, and 6 cases of inactive carriers showed increased HBV DNA viral load from ≤2.5 log IU/mL to 7.7 log IU/mL after completion of DAAs therapy. Treatment outcome Of HCV infection 75 (94%) patients achieved SVR.

**Conclusion:** HBV screening is strongly recommended for co-infected HCV/HBV patients before initiation and during DAA therapy. HBV reactivation can be prevented with pre-treatment screening and prophylactic treatment when necessary.

**Tenofovir alafenamide for treatment-naïve and nucleos(t)ide with hepatitis B virus infection**

Qin NING1, Di Wu1,2, Peng Wang1, Xiaoping Wu3, Yan Huang1, Youqin Yan1, Liang Chen1, Bing Pi1, Weiming Yan1

1Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology Wuhan China, 2The First Affiliated Hospital of Nanchang University Nanchang China, 3Xiangya Hospital, Central South University Changsha China, 4Wuhan Seventh Hospital, Department of Hepatology Wuhan China, 5Shanghai Public Health Clinical Center, Fudan University Shanghai China

**Background and Aims:** Tenofovir alafenamide (TAF) has been approved for the treatment of chronic hepatitis B (CHB). We aimed to assess the effectiveness and safety of TAF-based therapy in treatment naïve (TN) or experienced (TE) CHB patients.

**Methods:** This multicenter, prospective, real-word study included 500 CHB patients treated with TAF monotherapy or combining with
entecavir (ETV) for 144 weeks. Virological and biochemical responses and safety were evaluated (clinicaltrial.gov: NCT03752658).

**Results:** 404 patients (TN, 146; TE, 258) with available data were included in this interim analysis. 13.6% had cirrhosis at baseline. All TN patients and 164 TE patients received TAF alone, and 94 TE patients received TAF plus ETV. Of TN patients, 88.7% achieved virological response (HBV DNA <20 IU/mL) at week 96. 81.8% achieved biochemical response (ALT<40 U/L) at week 96. Among TE patients switching to TAF, virological response rate was significantly increased, from 67.8% at baseline to 91.7% at week 96 (P<0.05), and biochemical response rate was 79.7% at baseline and 92.1% at week 96. Among TE patients receiving TAF+ETV, virological response rate was significantly increased from 42.0% at baseline to 91.3% at week 96 (P<0.05), and biochemical response rate was significantly increased from 80.0% at baseline to 92.9% at week 96 (P<0.05). Of 75 TE patients with low level viremia at baseline (HBV DNA <2000 IU/mL), 61 achieved virologic response at week 96. Among patients with estimated glomerular filtration rate (eGFR) below 90 mL/min/1.73m² at baseline, eGFR was significantly improved at week 96 (P<0.05). Total cholesterol levels significantly increased at week 96 (P<0.05). TAF-based therapy was well-tolerated.

**Conclusions:** TAF-based therapy was effective in both TN and TE CHB patients, as well as those with low level viremia. TAF therapy showed a sustained improvement in renal glomerular function in patients with prior impaired renal function.

On-treatment liver stiffness measurements predict liver-related events in patients on HBV therapy

Yameng Sun1,2, Shuyan Chen1,2, Xiaoning Wu1,2, Tongtong Meng1,2, Jialing Zhou1, Bingqiong Wang1,2, Hong You1

1Liver Research Center, Beijing Friendship Hospital, Capital Medical University Beijing China, 2State Key Lab of Digestive Health Beijing China, 3National Clinical Research Center of Digestive Diseases Beijing China

**Background & Aims:** Baveno VII proposed a criterion based on liver stiffness measurements (LSM) to identify compensated advanced chronic liver disease (cACLD). LSM decreased significantly after antiviral therapy in chronic hepatitis B (CHB) patients. However, whether the on-treatment LSM-defined cACLD has prognostic relevance is unclear among CHB patients receiving antiviral therapy.

**Methods:** LSM was collected after at least 1-year of antiviral therapy. cACLD was defined (LSM > 15 kPa) or excluded (LSM < 10 kPa) based on Baveno VII criteria. LSM between 10 and 15 kPa were in the grey zone. Liver-related events (LREs) were defined as the first hepatic decompensation, hepato-cellular carcinoma, and death.

**Results:** A total of 694 CHB patients were included in this analysis. Patients were predominantly male (539, 77.7%) with a median age of 44 years. The median on-treatment LSM values were 7.6 (5.6, 10.7) kPa, with 494 (71.2%) patients in the non-cACLD group, 127 (18.3%) in the grey zone, and 73 (10.5%) in the cACLD group. In total, 12 decompensations and 16 HCC occurred during a median follow-up of 5.0 (3.0 - 6.8) years after the on-treatment LSM. The 5-year cumulative incidence of LREs were 1.8%, 6.3%, and 19.3% in non-cACLD, grey zone, and cACLD group, respectively (Log-rank, P<0.001). Compared to non-cACLD patients, those with cACLD had a higher risk of LREs after adjusting for age, sex, and platelet counts (adjusted HR = 3.98, 95%CI: 1.34-11.83, P = 0.013).

**Conclusions:** The on-treatment LSM could predict LREs in CHB patients during antiviral therapy.

Abstract Submission No. 101382

**Background:** In chronic hepatitis B (CHB)-related cirrhosis patients receiving long-term antiviral therapy, despite effective suppression of HBV viremia, the risk of hepatocellular carcinoma (HCC) persists. To personalize HCC surveillance, it is crucial to stratify the HCC risk. Mac-2 binding protein glycosylation isomer (M2BPGi), a serum liver fibrosis marker, was evaluated for its predictive role in this context.

**Methods:** We conducted a prospective cohort study to include HBV-related cirrhotic patients who received long-term antiviral therapy. They received continuous antiviral therapy with regular HCC surveillance. The M2BPGi were measured by Sysmex HISCL M2BPGi assay. Cox proportional hazard regression analysis was applied to identify risk predictors for HCC.

**Results:** A total of 501 patients were included and grouped in the “prior HCC” (n=47), “HCC” (n=56), and “no HCC” (n=398) groups at the time of M2BPGi measurement, with a median M2BPGi levels were 1.7, 1.3, and 1.0, respectively (P<0.001). Among the 454 patients without prior HCC, their median age was 60, and received a median 6.2 years of antiviral therapy. After a median of 3.3 years of follow-up, 56 patients developed HCC. M2BPGi levels <1, 1-3, and >3 mAU/mL significantly stratified the risk of HCC (logrank P=0.079). After adjusting for age, sex, and AFP, M2BPGi levels of 1-3 mAU/mL and >=3 mAU/mL increased the risks of HCC by 1.98 (95% CI: 1.05-3.74) and 2.55-fold (95% CI: 1.19-5.48), respectively, compared with M2BPGi <1 mAU/mL.

**Conclusions:** After 6 years of antiviral therapy, a high M2BPGi level proves valuable in predicting the development of HCC.

The effect of Peg-IFNα2b on metabolic status in patients with CHB combined with NAFLD

Qing Ye1,2,3,4, Huiling Xiang1,2,3,4, Jing Liang1,2,3,4, Baiguo Xu1,2,3,4, Baoxin Qian0, Chunyue Guo4

Department of Hepatology of The Third Central Hospital of Tianjin, China; The Third Central Clinical College of Naikai University Tianjin China; Tianjin Key Laboratory of Extracorporeal Life Support for Critical Diseases of Tianjin Tianjin China; Institute of Hepatobiliary Disease Tianjin China

Background: To investigate the effects of different antiviral treatment regimens on virological and metabolic related indicators in patients with chronic hepatitis B combined with NAFLD.

Methods: This is a prospective observational study. The patients with CHB who met the indications of antiviral treatment of the Guidelines were collected as the research objects, and were followed up for at least 24 weeks. The therapeutic effect and impact on metabolic related indicators, including BMI, CAP, TG, uric acid and metabolic disorder of chronic hepatitis B combined with NAFLD.

Results: The mean age of patients was 11.02±2.19 years. There were 57.46% male. The frequent risk factor was blood transfusion in 23.9% of children followed by vertical transmission in 47%, horizontal transmission in 13.4%, and a prior history of surgical or dental intervention was present in 17.2% of children.

Conclusion: In this study, vertical transmission was the most common route of transmission followed by vertical transmission. Additionally, 11% of family members were HBV positive. None had comitant HCV and HDV infection. All pregnant females should be screened. Children on chronic blood transfusion therapy should be screened annually. Additionally, birth dose Hepatitis B vaccination should be implemented as a key step in HBV prevention among Pakistani children.

Key Words: Hepatitis B virus, blood-borne transmission, perinatal transmission, Horizontal transmission, Vertical transmission

Abstract Submission No. 101437
O-0190
Methods: A total of 99 patients with hepatitis B were included in the study. Blood count was taken from each patient before nucleoside analog treatment, and after detecting HBV DNA negativity.

Results: Most of the patients had F2 (46.5%) and F3 (30.3%) liver fibrosis according to the Metavir scoring system. The average HBV DNA was 6.43±1.37 log copy/mL. Tenofovir was given to 54 (54.5%) patients, entecavir to 27 (27.3%) patients, and lamivudine to 18 (18.2%) patients. NLR and MPV were significantly lower after achieving HBV DNA negativity when compared to pretreatment values (p<0.018; p<0.001, consecutively)

Conclusions: NLR and MPV may be used for predicting or monitoring HBV DNA negativity and the effectiveness of nucleoside analogs in chronic hepatitis B patients.

Keywords: Neutrophil to lymphocyte ratio, mean platelet volume, HBV DNA, nucleoside analogs

Development and validation of new predictive model for immune tolerance of chronic HBV infection

Tongjing Xing1, Wentao Li1, Rui Huang2, Jian Wang2, Binhao Zhang1, Quipeng Wang1, Jiang Feng1

1Taizhou Hospital of Zhejiang Province affiliated to Wenzhou Medical University Taizhou China, 2Nanjing Drum Tower Hospital, Affiliated Hospital of Medical School, Nanjing University Nanjing, Jiangsu Province China

Objective To modify more accurate clinical and viral indicators and establish the new model for differentiating the different stages of chronic hepatitis B virus (HBV) infection based on liver histopathological changes.

Methods: The clinical and liver pathology data of chronic hepatitis B (CHB) patients undergoing liver biopsy were collected for retrospective analysis in the test and validation group. The area under the curve (AUC) of the receiver operating characteristic (ROC) was used to evaluate the diagnostic value for differentiating the different stages of chronic HBV infection.

Results: A total of 118 patients and 73 patients who met the diagnostic and exclusion criteria were selected as the test group and validation group. Multivariate analysis showed that HBeAg independently correlated with the IT and IC stages. The cutoff value of HBeAg used to quantitatively differentiate between IT and IC was 1335 S/CO and the AUC was 0.921 (95% confidence interval (CI): 0.836 to 0.971). A new prediction model of IT stage was established by using three indicators including HBeAg, HBsAg and HBV DNA. The AUC is 92.3% (95% CI: 86.4-98.2, P<0.001) using this prediction model. The sensitivity and specificity are 85.5% and 95.2%.

Conclusions: The high levels of HBeAg (1335s/co) rather than HBeAg positive might help to identify patients with the “true” IT stage. A predictive model for immune tolerance stage are established by combining three indicators. The new prediction model has significantly reduced the error rate compared with others standards.

Abstract Submission No. 101520

Achieving hepatitis B elimination in the Pacific Islands: test/treat is the way forward in Kiribati

Alice Lee1,3, David Hilmer2,3, Thomas Russell1

1Concord Repatriation General Hospital Sydney Australia, 2Baylor College of Medicine Houston Texas, 3Hepatitis B Free Sydney Australia

Background: In 2016, WHO declared that hepatitis B is a global health threat with elimination targets set to be achieved by 2030.[1] Progress towards elimination is slow[2]. One barrier to progress is the lack of screening and linkage to care in isolated populations where WHO guidelines cannot be applied. The remote islands of Kiribati are geographically isolated by vast stretches of ocean. Since 2019 our group has been providing hepatitis treatment in South Tarawa, where 50% of the country’s population lives.[6] Starting in 2022, a “test and treat” program has been initiated in the outer islands.

Methods: Eleven outer islands, totalling 5497 individuals, were screened with 867 positive tests. All positive females older than 15 years were offered tenofovir alafenamide which, despite its higher cost, can be started without routine creatinine testing. This age was chosen to include all potential mothers. Males testing positive were offered treatment at age 18.

Results: The overall prevalence was 15.8%; one-third of persons 24 years or younger tested positive. Highest rates were in the 30-34 age group with a prevalence of almost 30%. The program was well-accepted by-positive patients after education about the benefits/risks of treatment. Local providers found the protocol easy to implement.

Conclusions: Hepatitis B elimination using current guidelines is not achievable in remote locations such as the outer islands of Kiribati, and a new paradigm is needed. Despite its limitations, the “test and treat” strategy appears to be the most practical and cost-effective solution to meeting elimination goals in resource-limited regions.
Liver volume re-compensation in HBV-related decompensated cirrhosis after NUCs treatment

QIUAN ZANG1, Siyi Liu1, Juan Li1, Chengbin Zhu1, Qiao Zhang1, Yushan Liu1, Xiaonian Wu1, Yamin Wang1, Qiannan Wang1, Pan Huang1, Li Zhu4, Yingren Zhao5, Yingli He6
1Department of Infectious Diseases, The First Affiliated Hospital of Xi’an Jiaotong University, Xi’an, Shaanxi, China. Xi’an China, 2Institution of Hepatology, The First Affiliated Hospital of Xi’an Jiaotong University, Xi’an, Shaanxi, China. Xi’an China, 3Shaanxi Clinical Research Center for Infectious Diseases, Xi’an, Shaanxi, China. Xi’an China, 4Clinical Research Center for Infectious Diseases, The First Affiliated Hospital of Xi’an Jiaotong University, Xi’an, Shaanxi, China. Xi’an China

Background: NUCs therapy can effectively inhibit HBV replication and enhance the long-term prognosis of individuals with HBV-related decompensation, and some patients can achieve re-compensation. Liver volume serves as a crucial measure for assessing liver reserve function, the precise impact of liver volume on re-compensation remains uncertain.

Methods: We retrospectively included 159 HBV-related decompensated patients who received NUCs treatment. All patients underwent two abdominal CT scans. Software was utilized to measure the actual liver volume (LV), while the standard liver volume (ELV) was calculated by thoracic width. The liver volume ratio (LV/ELV%) was employed to eliminate individual differences. The changes of liver volume were dynamically observed during follow-up.

Results: The cumulative re-compensation rate over a period of two years was 37.7%. Prealbumin was linearly positively correlated with LV/ELV% (r = 0.515, P < 0.001), while prothrombin time was negatively correlated with LV/ELV% (r = -0.411, P < 0.001). After NUCs treatment, LV (979.13 ±256.42 cm3 vs 1081.72 ±273.67 cm3, P < 0.05) and LV/ELV% of HBV-related decompensated patients increased, while LV (985.02 ±247.78 vs883.38 ±261.91 cm3, P < 0.01) and LV/ELV% decreased in the persistent decompensated group. The risk of death was significantly increased in patients with LV < 950cm3 and LV/ELV% < 80%. The 5-year survival rate was significantly improved in patients with LV > 1000cm3 and LV/ELV% > 80%. The stomach survival rate was significantly different.

Conclusion: Patients with HBV-related decompensation can reverse liver fibrosis and enhance liver regeneration after receiving effectively NUCs treatment. Liver volume re-compensation is beneficial to long-term functional re-compensation.

Optimal Threshold of M2BPGi for Predicting Minimal HCC Risk in CHB Patients with Antiviral Therapy

Tai-Chung Tseng2,4, Cheng-Yuan Peng3,4, Yoo-Chun Hsu5, Chia-Chi Wang6,8, Tung-Hung Su6, Ming-Lung Yu10, Hsueh-Chou Lai6, Jia-Horning Kao2,4
1Division of Gastroenterology and Hepatology, Department of Internal Medicine, National Taiwan University Hospital Taipei Taiwan, 2Hepatitis Research Center, National Taiwan University Hospital Taipei Taiwan, 3Graduate Institute of Clinical Medicine, National Taiwan University College of Medicine Taipei Taiwan, 4Department of Medical Research, National Taiwan University Hospital Taipei Taiwan, 5School of Medicine, China Medical University Taichung Taiwan, 6Center for Digestive Medicine, Department of Internal Medicine, China Medical University Hospital Taichung Taiwan, 7Division of Gastroenterology, Department of Internal Medicine, Taipei Tzu Chi Hospital New Taipei Taiwan, 8School of Medicine, Tzu Chi University Hualien Taiwan, 9Division of Gastroenterology and Hepatology, Department of Internal Medicine, E- Da Hospital/T- Shou University Kaohsiung Taiwan, 10School of Medicine and Doctoral Program of Clinical and Experimental Medicine, College of Medicine and Center of Excellence for Metabolic Associated Fatty Liver Disease, National Sun Yat-sen University Kaohsiung Taiwan

Background & Aims: Mac-2 binding protein glycosylation isomer (M2BPGi) is a surrogate marker for liver fibrosis, predicting hepatocellular carcinoma (HCC) risk in chronic hepatitis B (CHB) patients receiving long-term antiviral treatment. However, the optimal threshold of M2BPGi to identify the minimal risk in these patients remains unclear.

Methods: We combined 2 cohort studies including 1283 Taiwanese CHB patients receiving long-term oral antiviral treatment. However, the optimal threshold of M2BPGi to identify the minimal risk in these patients remains unclear.

Results: We conducted a retrospective-prospective real-world study to explore the progression of liver disease after long-term drug withdrawal in HBBeAg positive postpartum woman. Finally, sixty HBBeAg positive postpartum woman discontinuing treatment for more than six months, 10 HBBeAg positive postpartum woman continuing treatment after delivery and 12 HBBeAg positive postpartum woman received NAAs treatment pre-pregnancy were eventually included.

Results: The baseline characteristics between three groups are comparable in terms of age, platelets count, APRI and FIB-4. The median follow-up time for postpartum woman discontinuing treatment was 28.8 months (6.0 - 89.2), which was comparable with the 27.6 months (6.6 - 111.7) for postpartum woman continuing treatment after delivery and 33.0 months (6.0 - 75.5, p=0.963) for postpartum woman received NAAs treatment pre-pregnancy. No postpartum women developed to liver cirrhosis or hepatocellular carcinoma in three groups. The liver stiffness value was 4.75 kPa (2.8 - 13.9) in postpartum woman discontinuing treatment, 4.1 kPa (2.7 - 6.7) in postpartum woman continuing treatment after delivery and 4.65 (3.7 - 6.4) in postpartum woman received NAAs treatment pre-pregnancy, which was comparable in three groups (p = 0.360). Moreover, APRI and FIB-4 were comparable in three groups (p > 0.05).

Conclusions: It is relatively safe for HBBeAg positive postpartum woman to discontinue NAAs treatment after delivery.
II, III, and IV compared to group I with hazard ratio (95% confidence interval, CI) of 2.7 (1.0-7.0), 4.5 (1.8-11.1), and 14.6 (6.3-33.8), respectively. This association remained significant when limiting the analysis to patients without liver cirrhosis at baseline. When stratifying these non-cirrhotic patients using single M2BPGi value of 0.55, patients with higher M2BPGi level (vs. lower M2BPGi level) were associated with increased HCC risk with age- and sex-adjusted hazard ratio of 4.3 (95% CI: 1.0-18.5). The annual HCC incidence of the non-cirrhotic patients with M2BPGi level <0.55 was 0.08% (95% CI: 0.02-0.3%).

Conclusion: In CHB patients receiving long-term antiviral treatment, our study identifies a serum M2BPGi threshold of 0.55 as a valuable marker for identifying individuals with minimal HCC risk.

Abstract Submission No. 101743

Effects of tenofovir alafenamide on the risk of hepatocellular carcinoma in Hong Kong

Lilian Y Liang1, 2, Terry CF Yip1, 2, Vincent WS Wong1, 2, Grace LH Wong1, 2
1Department of Medicine and Therapeutics, The Chinese University of Hong Kong Hong Kong China, 2Medical Data Analytic Centre (MDAC), the Chinese University of Hong Kong Hong Kong China

Background and Aims: Tenofovir alafenamide (TAF) is a novel pro-drug of tenofovir. We aimed to evaluate the one-year and two-year cumulative incidence of hepatocellular carcinoma (HCC) in patients with chronic hepatitis B (CHB) receiving TAF treatment.

Method: This is a retrospective cohort study in Hong Kong. CHB patients who were initially treated with TAF for at least six months were included. The baseline was defined as the start date of TAF treatment. Kaplan-Meier’s method was used to evaluate the cumulative incidence of HCC with 95% confidence interval (CI).

Results: We analyzed 444 CHB patients who initially received TAF for more than six months with a mean age of 54 years old, among whom 262 (59.0%) patients were males. The median TAF treatment duration was 24 months. During a median follow-up duration of 28 months, 10 TAF-treated patients developed HCC. We then censored the time at two years to evaluate the one-year and two-year cumulative HCC incidence. The one-year and two-year cumulative incidences of HCC in TAF-treated patients were 1.2% (95%CI: 0.5% - 3.0%) and 2.9% (95%CI: 1.4% - 5.7%), respectively (Figure). The one-year HCC incidence was comparable with that of entecavir (ETV)-treated CHB patients (1.3%, 95%CI: 1.1% - 1.4%) and higher than tenofovir disoproxil fumarate (TDF)-treated CHB patients (0.1%, 95%CI: 0.01% - 0.4%), which were reported by another retrospective cohort study in Hong Kong.

Conclusion: TAF treatment is associated with a comparable HCC risk with ETV treatment, but higher than TDF treatment.

A random survival forest model for predicting HBeAg seroconversion in CHB patients treated with NAs

Zhiyi Zhang1, Jian Wang2, 3, Fei Cao1, Shaoqiu Zhang2, Jiacheng Liu2, Juan Xia2, Xingxiang Liu4, Jie Li1, 2, 3, Rui Huang5, Chao Wu6
1Department of Infectious Diseases, Nanjing Drum Tower Hospital Clinical College of Nanjing University of Chinese Medicine Nanjing China, 2Department of Infectious Diseases, Nanjing Drum Tower Hospital, Affiliated Hospital of Medical School, Nanjing University Nanjing China, 3Institute of Viruses and Infectious Diseases, Nanjing University Nanjing China, 4Department of Hepatology, Huai’an an No. 4 People’s Hospital Hua’ian China

Background: Achieving Hepatitis B e-antigen (HBeAg) seroconversion is a pivotal treatment goal for patients with chronic hepatitis B (CHB) received nucleos(t)ide analogues (NAs) treatment. We developed a novel model to predict HBeAg seroconversion in CHB patients utilizing the Random Survival Forest (RSF) algorithm.

Methods: A total of 655 CHB patients who underwent NAs treatment from Nanjing Drum Tower Hospital (Nanjing cohort) and Huai’an No. 4 People’s Hospital (Huai’an cohort) were retrospectively analyzed. The Nanjing cohort was split into a training set (n = 320) and an internal validation set (n = 138) randomly with the ratio of 7:3. The Huai’an cohort formed as an external validation set (n = 197). A predictive RSF model was constructed and validated through discrimination and calibration. The Kaplan-Meier method was employed for evaluating the risk stratification of patients.

Results: The overall HBeAg seroconversion rates were 21.9%, 18.1%, and 11.7% in the training set, internal validation set, and external validation set, respectively. The RSF-based model exhibited good calibration and relatively high accuracy for predicting HBeAg seroconversion with a C-index of 0.873, 0.734, and 0.795 in the three sets, respectively. The model effectively stratified patients into high and low-points groups, with those scoring ≥ 14.1 demonstrating a significantly higher cumulative incidence of HBeAg seroconversion compared to those with scores < 14.1 (P < 0.0001).

Conclusions: We trained and externally validated a novel RSF-based model using commonly available predictors for accurately predicting HBeAg seroconversion in CHB patients receiving NAs treatment.

Impact of different ALT thresholds on the treatment eligibility of patients with CHB

Hao Wang1, Xiaoqian Xu1, Shan Shan1, Yuemin Nan2, Xiaoyuan Xu3, Hui Zhuang4, Hong You1, Jidong Jia1, Yuanyuan Kong1
1Beijing Friendship Hospital, Capital Medical University Beijing China, 2Third Hospital of Hebei Medical University Shijiazhuang China, 3Peking University First Hospital Beijing China, 4Peking University Health Science Center Beijing China

Background: Treatment initiation thresholds of alanine aminotransferase (ALT) differ among international guidelines for chronic hepatitis B (CHB). The study aimed to investigate the impact of different ALT treatment thresholds on the antiviral treatment eligibility of patients with CHB.

Methods: Clinical, biochemical, and serological information of untreated patients with CHB was retrieved from a nationwide hepatitis B registry database named China Registry of Hepatitis B. The rates of treatment eligibility according to the newly updated China guidelines were estimated based on different ALT treatment thresholds.

Results: A total of 5018 patients with CHB were included, comprising 3152 males (62.81%) and 1866 females (37.19%). The overall rate of treatment eligibility per the updated Chinese guidelines would increase from 86.89% to 93.74% if the ALT treatment threshold decreased from 50/40 U/L to 30/19 U/L (males/females). For patients aged ≥ 30 years and without a family history of HCC or cirrhosis, the rates of treatment eligibility would be increased by 13.7%, 36.5%, and 55.5% if the ALT treatment threshold decreased from 50/40 U/L to 40 U/L, 35/25 U/L,
and 30/19 U/L, respectively. Furthermore, lower treatment thresholds were associated with lower fibrosis burden as measured by APRI and FIB-4 scores.

Conclusions: Lowering the ALT treatment threshold could benefit more patients who are already at higher risk of disease progression. Expanding treatment in China would contribute to achieving the global goal of reduction in HBV-related mortality by 2030.

Abstract Submission No. 200097

Enhancer 1 unevenly activates the preS1 promoter of integrated HBV DNA and impacts HBsAg secretion

Fengmin Lu¹, Zhiqiang Gu¹
¹Department of Microbiology & Infectious Disease Center, School of Basic Medical Sciences, Peking University Beijing China

Background & Aims: The expression of HBsAg from integrated HBV DNA limits the achievement of functional cure for chronic hepatitis B. Thus, characterizing the unique expression and secretion of HBsAg derived from integrated HBV DNA is of clinical significance.

Approach & Results: A semi-quantitative analysis of intrahepatic HBsAg protein level in 563 treatment-naïve patients revealed that, in contrast to the significantly lower serum HBsAg levels, no significant decrease of intrahepatic HBsAg protein was observed in the HBsAg-negative patients, as compared to that in HBeAg-positive patients. In vitro studies of integrated HBV DNA mimic and long-read RNA sequencing of liver biopsy from patients revealed that, the lower HBsAg secretion efficiency seen in HBeAg-negative patients might be attributed to a relative increased proportion of 2.4 kb HBV RNA derived from integrated HBV DNA than covalently closed circular DNA (cccDNA), which resulted in L-HBsAg over-expression and the subsequent impaired HBsAg secretion. Mechanistically, the change of 2.4 kb HBV RNA proportion was caused by retargeting and uneven activation on preS1 (SP1) than preS2 (SP2) promoters by HBV enhancer 1 (EnhI) element, largely due to the loss of core promoter (CP) in integrated HBV DNA.

Conclusions: The secretion of HBsAg originated from integrated HBV DNA was impaired. Mechanistically, functional deficiency of CP leads to the promoter(s) retargeting of EnhI and uneven activation of SP1 over SP2, resulting in an increase in proportion of L-HBsAg.

Clinical Predictors of Functional Cure in CHB Patients Treated with Pegylated Interferon Alpha-2b

Yuanmei Chen¹-², Li Zhu¹, Chuan Wu Zhu¹
¹The Fifth People's Hospital of Suzhou su zhou China, ²Soochow University su zhou china

BACKGROUND & AIMS: Functional cure of chronic hepatitis B (CHB) is now the goal of treatment, but is rarely achieved with current therapy, such as pegylated interferon or long-term nucleos(t)ide analogues (NUCs). In this study, we aimed to explore the novel biological indicators in peripheral blood that can predict the efficacy of pegylated interferon alpha-2b (PEG-IFN α-2b) treatment for CHB and its clinical significance.

Methods: This observational study retrospectively enrolled CHB patients who were treated with PEG-IFN α-2b at the Fifth People's Hospital of Suzhou from January 2020 to May 2023, a total of 151 patients. We comprehensively analyze the expression levels of 83 indicators at the baseline in the patients, including hemocyte indicators, biochemical indexes and serum virologic markers. According to the achievement of functional cure (FC group, n = 43) or non-achievement of functional cure (NFC group, n = 108) at End-of-treatment, the data were analyzed and grouped. Statistical analysis using GraphPad Prism 9.5.1, SPSS 26.0, and MedCalc.

Results: Thirteen blood markers such as Hepatitis B surface antigen (HBsAg), hepatitis B antigen (HBeAg) and hepatitis B virus-deoxyribonucleic acid (HBV DNA) at baseline showed differences between the FC groups and NFC groups treated with PEG-IFN α-2b (p < 0.05). In contrast, women are more likely to achieve a functional cure with interferon therapy. HBsAg and lipoprotein(a) (Lp(a)) were associated with FC, with AUROCs of 0.87 (0.750 - 0.914, p < 0.0001) and 0.77 (0.657 - 0.846, p < 0.0001). A combination of HBsAg < 2.09 log10U/ml and Lp(a) > 123.3 mg/L at baseline had a effective predictive for FC with an AUROC of 0.902 (0.824 - 0.953, p < 0.001). In the advantaged groups treated with PEG-IFN-α-2b, Lp(a) and Mononuclear cell ratio (MONO %) also can be used to predict FC with AUROCs of 0.74 (0.587 - 0.981, p = 0.004) and 0.71 (0.552 - 0.842, p=0.001) besides HBsAg, HbsAb and HBV-DNA.

Conclusions: The Higher Lp(a) at baseline with PEG-IFN-α-2b, the easier to achieve functional cure. A predictive model constructed using baseline HBsAg and Lp (a) in CHB patients had good predictive value for achieving functional cure treated with PEG-IFN.

Keywords: PEG-IFN-α-2b, functional cure, lipoprotein(a), HBsAg, CHB

Cost of Hepatitis C Virus self-testing in Malaysia: A micro-costing study

Asra Asgharzadeh¹, Xiaohui Sem³, Huan-Keat Chan³, MR Abu Hassan³, E Reipold³, Peter Vickerman¹, Sonjelle Shilton², Josephine Walker¹
¹Bristol Medical school, University of Bristol, Bristol,UK Bristol United Kingdom, ²FIND Geneva Switzerland, ³Clinical Research Centre, Hospital Sultanah Bahiyah, Alor Setar Malaysia Malaysia

Background: The seroprevalence of Hepatitis C virus (HCV) is 3%-2.5% in Malaysia’s general population, with 4.6% prevalence in men who have sex with men (MSM), and 74.0% among people who inject drugs (PWID) on methadone maintenance treatment. A cohort study led by FIND, Malaysian AIDS Council and Malaysian Ministry of Health in 2021-2022 provided HCV self-tests (HCVST) through an existing online platform (Jom-Test) for HIV self-testing. We calculated the economic cost of HCVST in this study.

Methods: Participants were randomized to the intervention (249 in oral-fluid-based HCVST group, 250 in blood-based HCVST group, each receiving HCVST kits and instructions delivered by mail) and control groups (250, received information about facility-based HCV testing). Costs were gathered from program expenditure records in local currency units and converted to 2021 US Dollars. Research-specific costs were excluded.

Results: Most participants (92%) identified as MSM and 1% as PWID. There was 98% uptake of HCV testing in the HCVST arms compared to 51% in the control group. Total fixed costs were $113,463 (63.4% staff, 19.3% start up, 11.0% recurrent, 1.9% equipment, 1.3% overhead), with $4,125 total variable costs (test kit and delivery costs). There was 98% uptake of HCV testing in the HCVST arms compared to 51% in the control group. Total fixed costs were $113,463 (63.4% staff, 19.3% start up, 11.0% recurrent, 1.9% equipment, 1.3% overhead), with $4,125 total variable costs (test kit and delivery costs). Mean HCVST costs per patient were $165 (oral-fluid; $151 fixed and $14 variable) and $154 (blood; $151 fixed and $3 variable).
Conclusion: This micro-costing estimates the cost of HCVST in Malaysia, but cost-effectiveness of HCVST will depend on screening yield/prevalence, and numbers reached for testing. Few PWID participated, indicating that reaching this population may require different targeted approaches.

Hepatitis C Virus (HCV) Transmission among Japan’s Limited Risk Groups

Zayar Phyo1,2, Ko Ko1,2, Aya Sugiyama1,2, Tomoyuki Akita1,2, Kazuaki Takahashi1,2, Satoshi Tanaka1,2, Ryotaro Sakamori2, Junko Tanaka1,2

1Department of Epidemiology, Infectious Disease Control and Prevention, Graduate School of Biomedical and Health Science, Hiroshima University Hiroshima Japan, 2Project Research Center for Epidemiology and Prevention of Viral Hepatitis and Hepatocellular Carcinoma, Hiroshima University Hiroshima Japan, 3Department of Gastroenterology, National Hospital Organization, Osaka National Hospital Osaka Japan

Background: In Japan, despite low nationwide hepatitis C incidence, new infections persist among people who inject drugs (PWID) and men who have sex with men (MSM), hindering HCV eradication. Therefore, this study aimed to explore the status of HCV transmission among those groups in Japan.

Methods: Hiroshima University and the Gastroenterology Department of National Hospital Organization, Osaka, conducted a retrospective cohort study, recruiting HCV-infected patients from January 2009 to December 2023. Patients were recruited both prospectively and retrospectively, with serum samples collected before anti-HCV treatment. HCV RNA was extracted, and the full core region (576 base-pairs) was sequenced using the Sanger method. Genotype distribution was determined by phylogenetic analysis.

Results: We have already received 108 samples with additional 17 samples awaiting analysis. The updated results will be presented at the conference. As of now, the subjects were divided into four groups: non-MSM PWID (27), MSM PWID (15), MSM non-PWID (23), and non-MSM non-PWID (43). Of the 108 samples analyzed, 107 could be sequenced. The most common genotype among non-MSM PWID was 2a (56%), while in the MSM PWID, MSM non-PWID, and non-MSM non-PWID groups, it was 1b (87%, 65%, and 70%, respectively). By phylogenetic tree, clusters were found only in MSM but not in PWID. Moreover, non-MSM non-PWID were not closed to either MSM or PWID.

Conclusion: The transmission route for PWID is determined by MSM status, whereas the MSM group exhibited the same transmission route regardless of PWID, emphasizing prioritized control measures among MSM for HCV elimination in Japan.

Improvement of Hepatitis C Virus Care Cascade by In-hospital Reflex tEsting ALarm-C (REAL-C) model

Jonggi Choi1, Jina Park1, Won-Mook Choi1, Danbi Lee1, Ju Hyun Shim1, Kang Mo Kim1, Young-Suk Lim1, Han Chu Lee1

1Asan Medical Center, University of Ulsan College of Medicine Seoul South Korea

Background: WHO has set targets to eliminate viral hepatitis, including HCV infection, by 2030. Achieving these goals necessitates improved rates of diagnosis and treatment. We present the results of the in-hospital Reflex tEsting ALarm-C (REAL-C) model, which incorporates reflex HCV RNA testing and sending alarming messages for physicians.

Methods: We conducted a retrospective study at Asan Medical Center in Seoul, Republic of Korea, focusing on 1,730 patients newly testing positive for anti-HCV between March 2020 and June 2023. Three distinct periods were defined: pre-REAL-C (n=696), incomplete REAL-C (n=515), and complete REAL-C model periods (n=519). The primary outcome measured was the rate of HCV RNA testing throughout the study period. Additionally, the referral rate to GI department, linkage time for diagnosis and treatment, and the treatment uptake rate.

Results: Rate of HCV RNA testing increased significantly from 51.0% (pre-REAL-C) to 95.6% (complete REAL-C). This improvement was consistent across clinical departments, regardless of patients’ comorbidities. Among patients confirmed with HCV infection, the GI referral rate increased from 57.1% to 81.1% after the implementation of the REAL-C model. Treatment uptake rates among treatment-eligible patients was 92.4% during the study period. The mean days from anti-HCV positivity to HCV RNA testing decreased from 45.1 to 1.9. The mean days from the anti-HCV positivity to direct-acting antiviral treatment also decreased from 89.5 to 49.5 with the REAL-C model.

Conclusion: The REAL-C model, featuring reflex testing and alarming messages, effectively increased HCV RNA testing rates and streamlined care cascades. Our model facilitated progress toward achieving the WHO’s elimination goals for HCV infection.

Improving HCV Diagnosis: Precision Classification with Data Mining for Identifying Suspected Patients

Prihantini Prihantini1, Rifaldy Fajar2

1Bandung Institute of Technology Bandung Indonesia, 2Karlstad University Karlstad Sweden

The global prevalence of chronic hepatitis C virus (HCV) infection affects an estimated 58 million people, with approximately 1.5 million new infections reported annually. Consequently, the development of precise prediction models utilizing machine learning techniques is highly valuable. This study aimed to employ data mining techniques to classify individuals suspected of having HCV infection through various classification models. The research incorporated multiple methods, including data visualization with clean data, standard-scaler for data normalization, and the creation of dummy variables. Additionally, the study involved transforming and splitting data for training and testing, applying the Synthetic Minority Over-Sampling Technique (SMOTE) on the training dataset, and evaluating model performance using various metrics. Research outcomes were detailed based on patient-specific variables such as Age, Sex, ALB, ALP, ALT, BIL, CHE, CHOL, CREA, GGT, and PROT. The application of machine learning to a dataset of HCV-suspected patients demonstrated notable progress in healthcare precision. The Random Forest (RF) algorithm emerged as superior, exhibiting high accuracy and AUC values. This study underscores the importance of data mining, particularly highlighting the efficacy of the RF model, in advancing the detection of HCV. The integration of SMOTE effectively addressed imbalances in datasets, contributing to an improved model performance.
Factors of aggravation of esophagogastric varix after DAA in HCV decompensated cirrhotic patients

Yuki Tahata1, Hayato Hikita1, Satoshi Mochida2, Daiki Miki3, Akio Ido4, Nobuyuki Enomoto5, Rytotto Sakamor1, Takahiro Kodama1, Tomohide Tatsunii2, Tetsuo Takehara1

1Department of Gastroenterology and Hepatology, Osaka University Graduate School of Medicine, Suita, Japan, 2Department of Gastroenterology and Hepatology, Saitama Medical University, Saitama, Japan, 3Department of Gastroenterology and Metabolism, Graduate School of Biomedical and Health Sciences, Hiroshima University, Hiroshima, Japan, 4Digestive and Lifestyle Diseases, Department of Human and Environmental Sciences, Kagoshima University, Kagoshima, Japan, 5First Department of Internal Medicine, Faculty of Medicine, University of Yamanashi, Yamanashi, Japan

Background: Sustained virologic response (SVR) rate of direct-acting antiviral (DAA) therapy has been reported to be approximately 90% in patients with hepatitis C virus (HCV) associated decompensated cirrhosis. However, the factors associated with the aggravation of esophagogastric varix after DAA in patients with decompensated cirrhosis is unclear.

Methods: A total of 116 patients with HCV associated decompensated cirrhosis who started DAA therapy from February 2019 to December 2021 and for whom esophagogastric varix could be evaluated before and after DAA were included. We defined the aggravation of esophagogastric varix as rupture of varix and treatment for varix, and investigated the cumulative rate of and the factors associated with the aggravation of esophagogastric varix.

Results: The median age was 67 years, and 78% of patients were Child-Pugh B. The SVR rate was 95.7% (111/116). During the median observation period of 17.9 months from the start of DAA, 15 patients underwent treatment for varix and two underwent varix rupture. The 3-year cumulative aggravation rate of varix was 22.4%. In multivariate analysis, baseline status of esophagogastric varix was a significant predictor (p=0.018) and virologic failure (p=0.015) were significantly associated with the aggravation of esophagogastric varix. On the other hand, Child-Pugh class and alcohol intake were not.

Conclusions: Among patients with HCV associated decompensated cirrhosis treated with DAA, careful attention for the aggravation of esophagogastric varix are needed in patients with esophagogastric varix of F2 or more, higher baseline γ-glutamyl transpeptidase levels or virologic failure.
Abstract Submission No. 101032

Long term outcome following HCV treatment with Glecaprevir/Pibrentasvir in people who use drugs

Brian Conway1,2, Shana Yi3, Rossitta Yung1, Shawn Sharma1, Saina Beita1
1Vancouver Infectious Diseases Centre Vancouver Canada, 2Simon Fraser University Burnaby Canada

Background: Long-term outcome data after HCV treatment are limited, especially for individuals who use drugs. In this study, we investigated the long-term outcomes of patients who achieved SVR12 with G/P treatment.

Methods: We followed up with patients who achieved SVR12 (2019-22). Participants were documented to be viremic with any HCV genotype, non-cirrhotic, previously untreated for their infection, and actively using or injecting drugs before initiating treatment and all received G/P as three tablets daily for eight weeks within the context of a multidisciplinary model of care.

Results: We identified 108 subjects with a median age of 47 (22-75) years, 27.8% female, and 21.3% Indigenous. Nearly half (46.7%) did not have stable housing. Active drug use was confirmed in 97.2% of cases, and all participants achieved SVR12 during the study. Among the cured participants, 104 (96.3%) remained alive, and 4 individuals died of an opioid overdose. Out of the 104 patients, 98 (94.2%) remained HCV-free, and 6 (5.8%) were re-infected (rate of 0.006/100 person years). All 6 have recently initiated therapy and outcomes of repeat therapy are pending.

Conclusion: To achieve the goal of HCV elimination by 2030, a systematic approach to diagnosing and treating infections in PWUD will be crucial, including maintenance in long-term follow-up after cure. Most patients remain alive and cured, with a small number of overdose deaths in the context of an ongoing opioid crisis. Maintenance in follow-up allowed us to identify all cases of reinfection and re-initiate therapy within our program.

O-0212

Association of metabolic abnormalities with HCC development and survival in CHC patients after SVR

Mina Nakagawa1, Miyako Murakawa1, Masato Miyoshi1, Shun Kaneko1, Fukiko Kawai-Kitahata1, Sayuri Nitta1, Sei Kakinuma1, Yasuhiro Asahina1, Ryuichi Okamoto1
1Tokyo Medical and Dental University (TMDU) Tokyo Japan

Aims: The risk of carcinogenesis and liver-related or -unrelated death after SVR among patients with HCV has not been fully elucidated. Lifestyle factors have recently received attention as a risk factor, and we aimed to elucidate the association of metabolic abnormalities with liver carcinogenesis and prognosis after SVR with DAA.

Patients and Methods: A multicenter registry study, 1089 of 1267 patients without a history of HCC prior to DAA treatment enrolled from September 2014 to August 2023 who had achieved SVR were included in the study. The start date of follow-up is defined as the date of achieving SVR. Cox proportional hazards regression model was used to determine factors associated with the development of cancer and death among patients with and without prior history of HCC by using STATA 16 (StataCorp LP, College Station, TX, USA).

Results: The median number of follow-up was 3.8 years. Fifty-two patients (4.8%) without a prior history developed HCC. The following factors were identified as contributors to carcinogenesis: male (HR 2.0, p=0.018), diabetes (HR 2.1, p=0.023), SVR-Plt < 150,000 (HR 2.1, p=0.009), SVR-GGT (HR 2.5, p=0.015), and hypovascular nodule (HR 8.4, p<0.001). Extracted in univariate analysis. Even after adjustment for diabetes, dyslipidemia, alcohol consumption, obesity, and fatty liver, high SVR-GGT was associated with carcinogenesis (HR 2.4, p=0.030), and high SVR-GGT was a risk of carcinogenesis in the no alcohol consumption and no diabetes group (n=560) (HR 10.6, p<0.001). Next, life expectancy analysis revealed 45 deaths (4.1%) after SVR, 9% from liver cancer, 22% from other organ cancer, and 42% from cardiovascular death or CPA/drowning. Univariate analysis extracted factors involved in death as age >70 (HR 1.8, p=0.044), diabetes (HR 2.0, p=0.044), and Alb < 3.5 (HR 5.3, p=0.001), although only low Alb was significant (HR 3.6, p=0.023) after adjustment for metabolic abnormalities. When stratified by platelet level, diabetes (HR 3.1, p=0.017) and high SVR-GGT (HR 6.1, p=0.002) were associated with death in the group with platelets over 150,000.

Conclusion: Patients with elevated GGT after SVR are at high risk of HCC regardless of their metabolic abnormalities and lifestyle, and are also at high risk of death including cardiovascular events and malignancies of other organs. GGT levels after SVR may reflect hepatitis C-specific oxidative stress as well as induction by lifestyle factors such as alcohol consumption and diabetes mellitus.

Background: Pan-genotypic Sofosbuvir/Velpatasvir/Voxilaprevir (SOF/VEL/VOX) for 8-12 weeks has been shown highly effective, safe, and well-tolerated in treating patients with chronic hepatitis C (CHC) in POLARIS studies, however, there are no real-world setting data are available especially in treating naïve patients. This is the first opportunity from all over the world to demonstrate SOF/VEL/VOX efficacy and safety in Real World setting for the naïve patients.

Methods: SOF/VEL/VOX was approved in Turkey to use pan-genotypically for noncirrhotic naïve, cirrhotic naïve, treatment experienced patients for 8, 12 and 12 weeks respectively. We presented preliminary results of naïve CHC patients.

Results: Of the 180 patients 89.4% (n=161) were naïve, 42.9% (n=69) completed 12th week follow-up after the completion of the 8 (n=65) or 12 weeks treatment. Of these 69 patients 47.8% were female, median age was 59 (24-85), 77.3% were genotype 1 and 68.2% were genotype 1b. Median HCVRNA at the time of diagnosis were 1.310.000 IU/mL (19.426-10.000.000). Undetectable HCVRNA levels at the first month, end of the of treatment were 87.3% and 100% respectively and SVR12 were 98.6% (68/69). One relapsed patient was genotype 4. Median ALT levels were 36.0, 17.0 and 15.0 IU/L at diagnosis, end of the treatment and at the SVR12 follow-up respectively. There were not any treatment interruption or adverse event leading to treatment cessation.
Conclusion: SOF/VEL/VOX combination treatment is safe and presenting high SVR12 rates for the naïve CHC patients, further results with the high number of patients will be needed to prove this preliminary results.

Elevated GGT with metabolic factors enhances HCC development after HCV eradication
Hiroshi Naito1, Hitomi Sezaki1, Hiromitsu Kumada1
1Toranomon Hospital Tokyo Japan

Background: Gamma-glutamyltransferase (GGT) is known as an oxidative stress marker, but its association with the development of hepatocellular carcinoma (HCC) after sustained viral response (SVR) in patients infected with hepatitis C virus (HCV) is still unclear. We investigated the risk stratification using GGT after SVR.

Methods: The study enrolled 4773 patients who had achieved SVR with antiviral treatment and had no prior history of HCC. The definition for normal GGT was ≤32 IU/L in female and ≤64 in male. We analyzed the impact GGT and some metabolic factors at SVR 24 on subsequent HCC incidences.

Results: The median observation period was 6.7 years. Annual HCC rate was 4.7 per 1000 person-years. To examine the impact of GGT on the development of HCC, we classified the subjects into 4 groups; Group A: normal GGT with no alcohol and low BMI, Group B: normal GGT with alcohol or high BMI, Group C: high GGT with no alcohol and low BMI, Group D: high GGT with alcohol or high BMI. The 10-year cumulative HCC rates were in the order of Group D > B > C > A (8.2%, 4.9%, 1.8%, and 1.5%, respectively) (P < 0.001). Similar results were observed in multivariable Cox regression.

Conclusion: HCC incidence was lower in patients with normal GGT even if they had a history of alcohol consumption and obesity. On the other hand, elevated GGT enhance HCC development in those with a history of alcohol consumption or obesity. Further investigation is needed to clarify its mechanism.

Abstract Submission No. 101882

Mortality rates among patients successfully treated for HCV: A real world multinational cohort study
Fanpu Ji1, Eiichi Ogawa2, Takanori Suzuki3, Chung-Feng Huang4,5, Yu Jun Wong6, Hidenori Toyoda7, Sally Tran8, Makoto Chuma9, Mindie H. Nguyen10
1The Second Affiliated Hospital of Xi’an Jiaotong University Xi’an China, 2Kyushu University Hospital Fukuoka Japan, 3Nagoya City University Graduate School of Medical Sciences Nagoya Japan, 4Kaohsiung Medical University Kaohsiung China, 5Kaohsiung Medical University Hospital Kaohsiung China, 6Changi General Hospital Singapore Singapore, 7Singhealth Duke-NUS Medicine Academic Clinical Program Singapore Singapore, 8Ogaki Municipal Hospital Ogaki Japan, 9Stanford University Medical Center Palo Alto United States, 10Yokohama City University Medical Center Yokohama Japan

Objectives: HCV cure with SVR following DAA treatment reduces mortality risk, but data on risk factors associated with mortality following DAA-associated SVR are sparse. We aimed to fill in this gap.

Methods: 11,451 patients with SVR were enrolled in a real-world multinational cohort from 39 REAL-C clinical sites, and divided into four liver disease severity groups: non-cirrhosis (group 1), compensated cirrhosis (group 2), decompensated cirrhosis (group 3) and HCC (group 4). Follow-up started 24 weeks after antiviral treatment completion and ended-on-date-of-death or end-of-study follow-up (31/08/2023), whichever came first.

Results: 704 (6.2%) participants died during a 4.6±2.4 years follow-up: 124/207/133/240 in group 1/2/3/4, respectively, yielding corresponding all-cause mortality rates per 1000 person-years (95%CI) of 5.06 (4.24-6.03), 10.2 (8.86-11.6), 46.5 (39.2-55.1), and 49.4 (43.5-56.1). For patients without HCC at baseline, mortality rates stratified by age, sex, DM and liver fibrosis severity were shown in Fig.1A. For patients with HCC at baseline, mortality rates stratified by sex, age, and presence of active HCC were shown in Fig.1B. In multivariable analyses, older age(>65 years:3.1 times), male(1.4 times), fibrosis severity (4.7/1.7 times for decompensated/compensated cirrhosis), HCC receiving direct-acting antivirals (DAAs) including older regimens in routine practice, focusing on GT3/6.
Impact of DAAs on HCC Risk in Chinese Hepatitis C Patients: A 10-Year Follow-Up Study

Peng Huang1, Linna Jia1, Xiangyu Ye1, Yanzheng Zou2, Sheng Yang2, Rongbin Yu1

1Department of Epidemiology, Center for Global Health, School of Public Health, Nanjing Medical University Nanjing China, 2Department of Biostatistics, Center for Global Health, School of Public Health, Nanjing Medical University Nanjing China

Abstract Submission No. 100106
O-0217

Conclusions:

1. The long-term benefit of direct-acting antiviral agents (DAAs) therapy after achieving sustained virologic response (SVR) has not been clearly established, particularly in the Chinese population.
2. Achieving SVR is associated with significantly reduced risk of HCC in patients treated with DAAs.
3. Dynamic serum M2BPGi levels have been shown to predict hepatic fibrosis in HCV patients achieving SVR to DAAs.

Dynamic serum M2BPGi to predict hepatic fibrosis in HCV patients achieving SVR to DAAs

Chen-Hua Liu1, 2, 3, Ji-Yuh Lee3, Chun-Jen Liu4, 2, 4, Tung-Hung Su2, 5, Shang-Chin Huang4, Tai-Chung Tseng3, 2, 4, Pei-Jer Chen5, Jia-Horng Kao1, 2, 4, 6

1Department of Internal Medicine, National Taiwan University Hospital Taipei Taiwan, 2Hepatitis Research Center, National Taiwan University Hospital Taipei Taiwan, 3Department of Internal Medicine, National Taiwan University Hospital, Yun-Lin Branch Douliou Taiwan, 4Graduate Institute of Clinical Medicine, National Taiwan University College of Medicine Taipei Taiwan, 5Department of Internal Medicine, National Taiwan University Hospital Bei-Hu Branch Taipei Taiwan, 6Department of Medical Research, National Taiwan University Hospital Taipei Taiwan

Background:

Little is known about the role of dynamic serum Mac-2 binding protein glycosylation isomer (M2BPGi) levels to assess hepatic fibrosis in hepatitis C virus (HCV)-infected patients who have achieved sustained virologic response (SVR12) to direct-acting antivirals (DAAs).

Methods:

Serum M2BPGi levels and liver stiffness measurement (LSM) using transient elastography (TE) were evaluated in 638 patients who achieved SVR12. Receiver operating characteristic (ROC) curves were generated to assess the diagnostic accuracy of baseline and SVR12 serum M2BPGi levels in distinguishing a fibrosis stage ≥F2, ≥F3, and F4. The selected M2BPGi cutoff levels at baseline and SVR12 were determined based upon the maximal Youden index, and optimized positive and negative likelihood ratios (LRs).

Results:

Compared to baseline level, the median serum M2BPGi level at SVR12 significantly decreased (1.55 versus 0.92, p < 0.001), irrespective of the fibrosis stage. The areas under ROC curves (AUROCs)
of M2BPGi in predicting a fibrosis stage of ≥ F2, ≥ F3, and F4 were 0.854, 0.914, and 0.947 at baseline, and 0.814, 0.913, and 0.937 at SVR12, respectively. M2BPGi, with cutoff values of 2.05, 2.83, and 3.98 at baseline, and 1.49, 1.58, and 1.75 at SVR12 exhibited predictive power for the presence of ≥ F2, ≥ F3, and F4, with positive likelihood ratios (LRs) of ≥ 10. The diagnostic accuracy of M2BPGi appeared to increase with the severity of hepatic fibrosis.

**Conclusions:** The dynamic serum M2BPGi level can monitor the severity of hepatic fibrosis in HCV-infected patients before and after SVR12 to DAA treatment.

**Non specialist training: an effective method for micro-elimination of hepatitis C in hospital**

Qing Ye1,2, Yu Zhu2,3, Fushuang Hai1,2, Yu Wu2,4, Tao Han5

1Department of Hepatology of The Third Central Hospital of Tianjin, China Tianjin China, 2The Third Central Clinical College of Naikai University, Tianjin, China Tianjin China, 3Department of Medical Laboratory of The Third Central Hospital of Tianjin, China Tianjin China, 4Department of Infection of The Third Central Hospital of Tianjin, China Tianjin China, 5Tianjin Union Medical Center, Naikai University Affiliated Hospital, Tianjin, China Tianjin China

**Background/aims:** WHO aims to eradicate HCV infection by 2030. However, the current situation of eliminating hepatitis C is not satisfactory, as many patients were missed. The purpose of this study was to explore an effective method for micro-elimination of hepatitis C in hospital.

**Methods:** Online questionnaire was used to investigate the HCV knowledge of the non specialists from 7 medical centers in Tianjin. Then they received a brief training for the diagnosis and treatment of hepatitis C. Then the effect of training was investigated by rate of referral, diagnosis and treatment of HCV patients.

**Results:** More than half of hepatitis C antibody positive patients are distributed in non liver disease departments. 459 questionnaires were retrieved and we found that only 26.4% non specialists who found hepatitis C antibody positive were familiar with the following screening step (HCV RNA). Additionally, 8.7% of doctors were familiar with the DAA drugs for hepatitis C treatment, and 78.4% were completely unaware of the hepatitis C medical insurance policy. The rate of HCV screening, diagnostic and treatment in non liver disease departments were 67.2%, 41.1% and 47.3% before trained, however, the rates were 92.3%, 92.1% and 94.4% after the training (P all <0.001).

**Conclusions:** There was a huge obstacle to the elimination because the low awareness of hepatitis C in non specialists. A brief training could significantly improve the effect of diagnosis and treatment. This may be an effective and fast way for us to achieve the 2030 goals.

**Clinical utility of HCV core antigen measurement for HCVAb-positive patients towards HCV elimination**

Satoru Joshita1,2, Yuki Yamashita2, Hiroyuki Kobayashi2, Takeji Umemura2

1NHl Yodakubo Hospital Nagawa town Japan, 2Shinshu University School of Medicine Matsumoto Japan

The cascade of hepatitis C virus (HCV) cure/care depends on the link-age of medical examination and treatment initiation to eliminate HCV. We conducted a prospective, non-interventional, observational study from April 2022 to March 2023 targeting patients who underwent HCV antibody testing during hospitalization or outpatient visits. HCV core antigen levels were additionally measured using residual serum from HCV antibody-positive cases. We encouraged patients to receive medical care if both samples were positive. The HCV antibody positivity rate was 4.4% (390/8,805 cases), with a significantly higher rate in outpatient testing (4.6%) than in inpatient testing (2.3%) (P=0.002). Among the 378 HCV antibody-positive patients with sufficient residual serum, HCV core antigen positivity rate was 8.2% (31/378 cases) and significantly higher in patients with HCV antibody level ≥10 COI (n=249) than in those with <10 COI (n=129) (11.6% vs. 1.6%, P=0.002). The median age of the HCV core antigen-positive individuals (14 male and 17 female) was 76 years (range: 18-92 years). Apart from 2 patients with no scheduled visits, the remaining 29 patients were urged to undergo detailed examination and follow-up. One patient tested negative for HCV RNA. Nine of the remaining 28 cases (32.1%) were prescribed direct-acting antiviral (DAA) treatment, 13 (46.4%) were deemed DAA-ineligible due to such complications as hepatocellular carcinoma, and 6 (21.4%) had no interest in therapy. Performing HCV core antigen measurement with residual serum from HCV antibody-positive individuals may be useful for identifying HCV carriers and directing them towards additional examination and treatment.

**Long-term Serum Ferritin Dynamics in Patients Receiving Antiviral Treatment for HCV Infection**

Yu-Ping Chang1,3, Chun-Jen Liu1,2,3, Tung-Hung Su1,2, Shang-Chin Huang3, Tai-Chung Tseng4, Pei-Jer Chen1,2,3, Jia-Horng Kao1,3, Chen-Hua Liu1,2,4

1Department of Internal Medicine, National Taiwan University Hospital Taipei Taiwan, 2Hepatitis Research Center, National Taiwan University Hospital Taipei Taiwan, 3Graduate Institute of Clinical Medicine, National Taiwan University College of Medicine Taipei Taiwan, 4Department of Internal Medicine, National Taiwan University Hospital Bei-Hu Branch Taipei Taiwan, 5Department of Medical Research, National Taiwan University Hospital Taipei Taiwan, 6Department of Internal Medicine, National Taiwan University Hospital, Yun-Lin Branch Douliou Taiwan

**Background:** Data regarding the long-term serum ferritin dynamics and factors associated with the trends of changes in patients receiving antiviral treatment for hepatitis C virus (HCV) infection are limited.

**Methods:** Serum ferritin levels were evaluated biannually in 1538 HCV-infected patients receiving direct-acting antiviral (DAA) or interferon (IFN)-based treatment after confirming sustained virologic response (SVR12) or not. We compared the ferritin dynamics in patients with factors of interest using the generalized estimating equation (GEE). Univariate and multivariate analyses were performed to identify predictors associated with serum ferritin evolutions.

**Results:** By univariate analysis, patients achieving SVR12, aged > 50 years, having metabolic dysfunction-associated steatotic liver disease (MASLD), or pre-treatment HCV RNA level > 2,000,000 IU/mL were associated with different ferritin dynamics. Multivariate analysis showed that patients achieving SVR12 (adjusted slope coefficient difference: -7.50 ng/mL/year [95% CI: -3.37 to -11.63], p < 0.001), and those with MASLD (adjusted slope coefficient difference: 4.16 ng/mL/year [95% CI: 0.41 to 7.91], p = 0.0022) were independently associated with ferritin evolutions. In patients achieving SVR12, the

Collaboration with community and hospital contributes to HCV elimination in database

Yongzi Wei1, Dacheng Qin2, Linping Zheng3, Jielian Sun4, Bingxue Yu5, Jianlin Wu6, Yong Huang7

1Wuming Hospital of Guangxi Medical University Nanning China, 2Tengxian People's Hospital Wuzhou China

Background: Still a big gap in HCV patients who diagnosis-but-un-treated (DBU) in China. It is the priority for HCV elimination in China. Methods: The Centers for Disease Control and Prevention (CDC) in Waming District of Nanning City and Tengxian County of Wuzhou City in Guangxi collaborate with community hospitals and community service centers, worked on recalling all the patients with HCV-Ab(+) from 2004 to 2021 in their data pool. Once the patients come back to the community hospital, doctors will perform the blood sampling for HCV RNA testing for them. The doctor in community hospital will phone the patients about the result and referred the patients with HCV RNA(+) to hepatologist. And then the patients will receive DAA treatment after communication with hepatologists.

Results: In the past 10 months, 4995 previously reported hepatitis C patients were recalled, and 1610 cases were contacted successfully. Among them, 1006 patients were tested for HCV RNA testing. The positive rate of nucleic acid was 36.5% (367/1006). At present, 16.34% (60/367) of CHC patients have been successfully referred to hepatologists for further assessment, of which 13.35% (49/367) have been successfully referred to hepatologists for further assessment, of which 13.35% (49/367) have received DAA treatment. Another 318 patients were still in the telephone follow-up and had agreed to go to the liver disease clinic for treatment in the near future.

Conclusion: CDC collaborates with community hospital and community service center contribute to HCV elimination for the DBU patients.

HCV Micro-elimination in private Hemodialysis center

Fang Cao1, Kerun An1, Guocheng Zhang1, Hongjun Luo2, Bin Yao3, Xi'e Pan3, Xiu Ai4, Xiaohui Luo5, Fuli Guo6, Xue Li3

1Sichuan Sansong medical management group Chengdu China, 2Chengdu Wenjiang Yufu Hospital, Sichuan Chengdu China, 3Chengdu Chenghua Sansong kidney disease Hospital,Sichuan Chengdu China, 4Chengdu Sansong Nephropathy Hospital,Sichuan Chengdu China

Objective: This study aimed to explore standard operation procedure(SOP) of HCV elimination in private hemodialysis centers.

Methods: This was a multi-center study. A survey would be provided to medical workers and HCV-Ab(+) patients to access the awareness of the people regarding no patients accepted HCV RNA testing and anti-viral treatment in 5 private hemodialysis centers. Then HCV knowledge education would be hold. After education, HCV RNA testing would be recommended for anti-HCV(+) patients. Finally HCV RNA(+) patients will be accompanied by dedicated medical workers throughout “green channel” to hepatologists for SOF/VEL treatment.

Results: From October to November 2022, 247 medical workers and 45 anti-HCV(+) patients completed survey. 89% medical workers and 100% medical patients have no idea about HCV and only 7~9% medical workers would recommend patients to receive HCV screening and treatment. All the medical workers and HCV-Ab(+) patients were educated through 9 medical education tours. From March to May 2023, 100% (44/44) HCV-Ab(+) patients received HCV RNA testing, with a positivity rate of 38.6% (17/44). Till September 2023, 84.6%(11/14) patients received SOF/VEL treatment. The sustained virological response rate at 12 weeks of treatment(SVR12) was 100%(11/11).

Conclusion: This SOP can great contribute to HCV elimination in private hemodialysis centers.

Real-world study of Sofosbuvir/Velpatasvir for cirrhotic patients with genotype 3 HCV infection

Yongrui Yang1, Kang Huang1, Lei Wu1, Jinsong Bai1, Junyi Li1, Shenhao Li1, Li Liu1, Haiwen Li1, Zhirong Zhao1, Yingrong Du1

1The third people’s hospital of Kunming city, Yunnan Provincial Infectious Disease Clinical Medicine Center, Kunming Yunnan, China Kunming China

Objective: To explore the efficacy and safety of Sofosbuvir/Velpatasvir ± ribavirin (SOF/VEL±RBV) in the treatment of genotype 3(GT3) chronic hepatitis C cirrhotic patients.

Methods: Patients diagnosed as GT3 HCV infection and treated at the Third People’s Hospital of Kunming city from June 2018 to February 2023 were included. All patients had liver cirrhosis and treated with SOF/VEL±RBV for 12 weeks. Virologic response, liver and kidney function and adverse effects(AE) were analyzed.

Results: A total of 319 patients were included, including 308 with SOF/VEL±RBV group and 11 with SOF/VEL group(RBV intolerable). After 12 weeks off-treatment, the sustained virological response (SVR12) rate in SOF/VEL±RBV group was 98.37% (303/308), and the levels of APRI score and FIB-4 index were decreased compared with baseline (P<0.05). The results of total bilirubin, AST and ALT were all decreased compared with baseline(P<0.05). SVR12 rate of SOF/VEL group was 72.73% (8/11). Most common AEs were mild hemolytic anemia (15.26%), fatigue (8.12%) and rash (8.77%) in SOF/VEL±RBV group, and fatigue (9.09%) in 1 case in SOF/VEL group.

Conclusion: SOF/VEL±RBV could achieve higher SVR12 and well tolerated for GT3 HCV infected patients either with compensated cirrhosis or decompensated cirrhosis patients.

Abstract Submission No. 100592

Baseline FIB4 is superior to FIB4 at SVR12 to predict HCC occurrence following DAA-attained SVR12

Ashley Tiong1, Pooja Devan1, Jean E Neo1, Wei Xuan Tay2, Yu Jun Wong3

1Singapore General Hospital, Singapore, 2Singapore National Cancer Centre, Singapore, 3Singapore National Cancer Centre, Singapore

Objective: This study aimed to explore standard operation procedure(SOP) of HCV elimination in private hemodialysis centers.

Methods: This was a multi-center study. A survey would be provided to medical workers and HCV-Ab(+) patients to access the awareness of the people regarding no patients accepted HCV RNA testing and anti-viral treatment in 5 private hemodialysis centers. Then HCV knowledge education would be held. After education, HCV RNA testing would be recommended for anti-HCV(+) patients. Finally HCV RNA(+) patients will be accompanied by dedicated medical workers throughout “green channel” to hepatologists for SOF/VEL treatment.

Results: From October to November 2022, 247 medical workers and 45 anti-HCV(+) patients completed survey. 89% medical workers and 100% medical patients have no idea about HCV and only 7~9% medical workers would recommend patients to receive HCV screening and treatment. All the medical workers and HCV-Ab(+) patients were educated through 9 medical education tours. From March to May 2023, 100% (44/44) HCV-Ab(+) patients received HCV RNA testing, with a positivity rate of 38.6% (17/44). Till September 2023, 84.6% (11/14) patients received SOF/VEL treatment. The sustained virological response rate at 12 weeks of treatment(SVR12) was 100%(11/11).

Conclusion: This SOP can great contribute to HCV elimination in private hemodialysis centers.
INTRODUCTION: Direct-acting antiviral (DAA) has cured millions of patients with chronic hepatitis C (CHC). The need for hepatocellular carcinoma (HCC) surveillance after DAA-attained SVR12 among non-cirrhotic CHC patients remained a matter of debate. We sought to compare the performance of baseline and FIB4 at SVR12 to predict the HCC occurrence in CHC patients after DAA-attained SVR12.

Methods: This is a post-hoc analysis including all consecutive genotype 3 CHC patients treated with sofosbuvir/velpatasvir between 2018-2019 in our institution (PMID: 3321740). Primary predictor was FIB4 at baseline and SVR12 (FIB4-SVR12). Primary outcome was new HCC.

Results: A total of 779 CHC patients with SVR12 were included. Over median follow-up of 4 years, 2.3% developed HCC after SVR12. All HCC developed in patients with cirrhosis and male gender. Patients who developed HCC were older with prior history of HCC (44.4% vs 1%, p=0.001) and higher median FIB4 score at SVR12 (3.9 vs 1.5, p<0.001). HCC risk increases with both baseline FIB4 (low-risk: 0%, moderate-risk: 0%, high-risk: 9.8%, p=0.001) and SVR12-FIB4 (low-risk: 0%, moderate-risk: 2.0%, high-risk: 18.4%, p=0.001), with excellent AUC (Baseline: 0.92, SVR12: 0.88). Using FIB4-SVR12≥3.25 to select post-SVR CHC patients for HCC surveillance significantly reduce the proportion of patients requiring HCC surveillance (87.8% vs 80.7%, p=0.0018) at the expense of missing more HCC than baseline FIB4 (1.6% vs 0.2%, p=0.0123).

Conclusion: FIB4 accurately risk stratify post-SVR HCC in CHC patients, however a small but persistent risk of HCC remained when post-SVR12 FIB4 was used to select patients for HCC surveillance.

Evaluating HCV Point-of-Care Testing - a Real-World Study on People Who Inject Drugs in Singapore

Alyssa Sim1, Kuo Chao Yew1, Robert Hawkins2, Sanchalika Acharyya3, Samuel Wong4, Yuan Heng Lim5, Angela Li Ping Chow6, Wei-Yen Lim1, Hwee Pin Phua1, Chen Seong Wong2, Wei Lyn Yang1

1Department of Gastroenterology & Hepatology, Tan Tock Seng Hospital Singapore Singapore, 2Department of Laboratory Medicine, Tan Tock Seng Hospital Singapore Singapore, 3Clinical Research & Innovation Office, Tan Tock Seng Hospital Singapore Singapore, 4HCSA Highpoint Halfway House, HCSA Community Services Singapore Singapore, 5Lee Kong Chian School of Medicine, Nanyang Technological University Singapore Singapore, 6Department of Preventive and Population Medicine, Tan Tock Seng Hospital Singapore Singapore, 7National Centre for Infectious Diseases Singapore Singapore

Background: The target for HCV elimination is set at ≥90% of Chronic HCV diagnosed. Point-of-care testing (POCT) has the potential to increase diagnosis. We critically evaluated the performance of POCT using OraQuick® HCV Rapid Antibody Test.

Method: People who inject drugs (PWID) from 4 Halfway Houses in Singapore were concurrently screened for HCV via blood for Anti-HCV Serology and using fingerstick capillary whole blood (FSWB) and oral mucosal transudates (OMT) for POCT interpreted by trained personnel. A blinded study team-member independently assessed images of POCTs.

Results: Of 207 participants, 37.3% were Anti-HCV positive. Compared to anti-HCV serology, POCT performance on FSWB and OMT were: Sensitivity 81.8 (73.2 - 90.4), 74.0 (64.2 - 83.8), p=0.014; Specificity 100.0 (100.0 - 100.0), 98.5 (96.3 - 100), p= 0.157. Sub-group analysis of 30-minute pre-test nil-by-mouth instruction in 103 subjects reported Sensitivity 77.5 (64.6 - 90.4), 77.5 (64.6 - 90.4) and Specificity 100.0 (100.0 - 100.0), 98.4 (95.3 - 100.0). OMT positivity and false-negative had no correlation with sample analytical cutoff index signal distribution of Anti-HCV Serology. Inter-class correlation between real-time and imaging readings of POCT for FSWB/OMT at 20 min/40 min were Kappa 0.9666, 0.9674; 0.8803, 0.8940.

Conclusion: We observed a lower-than-reported sensitivity of OraQuick® POCT with comparable performance for FSWB and OMT. Factors such as difference in oral fluid immunoglobulin secretion, sample collection, could affect POCT reading. Nevertheless, POCT OMT remains a promising diagnostic tool for its adaptability, ease-of-performance in serial or self-testing for HCV naive population.
The people’s hospital of Jiulongpo district, Chongqing, China
Chongqing China, 1Jiulongpo district center for disease control and prevention, Chongqing, China, 2Institute for AIDS/STD Control and Prevention Chongqing Center for Disease Control and Prevention Chongqing China

Background: Diagnosis and treatment of recently acquired HCV in people living with HIV (PWLH) was still limited in China.

Methods: This prospective study would identify acquired HCV patients in the HIV outpatient clinic in Jiulongpo Hospital of Chongqing. During regular follow-up, PWLH with abnormal liver function took HCV-Ab screening, and HCV RNA testing was provided for the HCV-Ab positive patients. HCV RNA positive patients would receive Sofosbuvir/Velpatasvir (SOF/VEL) treatment for 12 weeks.

Results: From May 2021 to October 2023, 76 patients with recently acquired HCV were identified among PLWH. All the patients were HCV-Ab within 6 months. 93.4% (71/76) was sexual transmission. Homosexual and heterosexual were 71% (54/76) and 22.4% (17/76), respectively. 6.6% (5/76) was transmitted by drug injection. After 12 weeks post-treatment, 100% patients achieved SVR12, and 86% (65/76) patients had ALT normalization. All the patients (76) treated with EFV/TDF/3TC or AZT/TDF/LPVr were switched to B/E/TAF before anti-HCV treatment. SOF/VEL treatment was well tolerated. No serious adverse events (AEs) were reported.

Conclusion: More attention should be paid for recently acquired HCV infection among PLWH, especially for patients with actively sex. Regular HCV screening and prompt anti-HCV treatment could effectively prevent HCV transmission in PLWH.

Abstract Submission No. 101072

Frequency of cognitive impairment in patients with chronic HCV and its correlation with CTP Score.

Anoshia Fahad1, Sana Hussain1
1Dr. Ruth KM Pfau Civil Hospital Karachi Pakistan

Introduction: It is estimated that approximately 100 million persons have been infected with HCV. HCV is detected in CSF raising the possibility of its extra hepatic replication resulting in cognitive impairment. CHC patients already have reduced health related quality of life and cognitive impairment will even make it worse.

Methods: This was a cross sectional study, conducted from January 2023 to June 2023. All patients with hepatitis C fulfilling the inclusion criteria were included. Baseline characteristics were collected on pre-designed proforma. Montreal Cognitive Assessment was used to assess the cognitive impairment in HCV patients. Patients with score of 18-25 were classified as having mild, 10-17 as moderate and less than 10 as severe cognitive impairment.

Results: Total 78 consecutive patients were enrolled. Mean age of patients was 43.6 ±12.2. Males and females were 59% & 41%. Overall, 14 (17.9%) patients had normal cognitive function, while mild, moderate and severe CI was seen in 28.2%, 33.3% and 20.5%. Normal cognitive function was found in 11 patients of CTP class A, 3 in CTP class B and none in CTP class C while none of the patient in CTP class A had severe CI followed by 4 and 12 patients in CTP class B & C.

Conclusion: We concluded that majority of the patients having HCV associated cognitive impairment were males and more patients in CTP class C had severe cognitive impairment. So actions are needed for early detection and treatment of HCV for better health outcomes.

The Risk for Tumor Progression of HCV-related Hepatocellular Carcinoma after curative treatment

Hiroko Ikenaga1, Sawako Uchida-Kobayashi1,2, Yoshimi Yukawa-Muto1, Naoshi Odagiri1, Kohei Kotani1, Hiroyuki Motoyama1,2, Ritsuzo Kozuka1, Atsushi Hagihara1, Etsushi Kawamura1, Hideki Fuji1, Masaru Enomoto1, Akihiro Tamori1, Norifumi Kawada1
1Department of Hepatology, Graduate School of Medicine, Osaka Metropolitan University Osaka Japan, 2Department of Premier Preventive Medicine, Graduate School of Medicine, Osaka Metropolitan University Osaka Japan

Background: HCC shows poor prognosis after progression to intermediate or advanced stage (BCLC stage B-D). However, tumor progression risk and the effect of DAA therapy after curative HCC treatment remain unclear.

Methods: We conducted a retrospective cohort study of patients with HCV-related HCC. We estimated the risk of tumor progression (defined as progression to BCLC stage B-D) by time-varying Cox regression analysis.

Results: Among 558 patients with HCV-related HCC, 165 patients were included in the analysis. The median age was 72 years, 96 were men, 53 received surgical resection, and 72 received DAA therapy after HCC treatment. FIB-4 index and liver-to-spleen (L/S) ratio for CT attenuation were calculated, and the median were 5.21 and 1.16, respectively. We recorded 56 incidences of tumor progression (29, 13, 8 and 6 cases were due to multiple nodules, portal invasion, extrahepatic metastasis, and deterioration of hepatic reserve, respectively). In univariate analysis, DAA-induced SVR (HR 0.27, p=0.001), FIB-4 index (HR 1.10, p=0.001), L/S ratio (HR 0.67, p<0.002), history of IFN therapy (HR 0.40, p=0.02) and ALBI score (HR 2.39, p=0.02) were associated with the risk of tumor progression. Multivariate analysis showed DAA-induced SVR, FIB-4 index and L/S ratio were associated with the risk.

Conclusions: This study suggested DAA-induced SVR reduced, and liver fibrosis (FIB-4 index) and liver steatosis (L/S ratio) increased the risk for tumor progression.
37 years with Malmö Needle Exchange Program at the center: From HIV prevention to HCV elimination

Marianne Alanko Blome,1,2,3, Pernilla Isendahl,1, Katja Troberg,3, Martin Bråbäck4,5, Anna O Jerkeman1
1Lund University, Department of Clinical Sciences, Section for Infectious Diseases, Sweden Malmö Sweden, 2Regional Office of Communicable Disease Control and Prevention Malmö Sweden, 3Department of Infectious Diseases, Skåne University Hospital Malmö Sweden, 4Addiction Center, Division of Psychiatry Malmö Sweden, 5Lund University, Faculty of Medicine, Department of Clinical Sciences Lund, Psychiatry Lund Sweden

Background: Malmö needle exchange program (MNEP) opened at the Infectious disease department at the Skåne University Hospital in 1987 to prevent HIV transmission among people who inject drugs. Since then, MNEP has evolved according to the needs of the participants.

Methods: MNEP has reached > 5200 persons, with 600 individuals conducting 6000 visits per year. Injection material and risk reduction counselling, medical care and psychosocial support are provided. Interviews on sociodemographic facts and substance use are combined with testing for HIV, hepatitis A (HAV), B (HBV) and C (HCV). Vaccinations against HAV and HBV are provided. HCV treatment and Take Home Naloxone was introduced on site in 2018.

Results: While HIV and HBV transmission remained low, HCV prevalence (80% anti-HCV positive, of whom >50% viremic) and incidence (31.5/100 pyr in 1997-2005) were previously high. A pilot study offering HCV treatment on site (2018, n=50) found high rates of adherence (94%) and sustained virological clearance (90%), with 9 reinfected so far. By large scale treatment the overall HCV prevalence among MNEP participants has declined to <20%. Naloxone is now distributed by all NEPs and OAT clinics in Skåne region. To date, 900 kits out of the 5700 distributed have been used to reverse opioid overdoses.

Conclusion: A NEP with ID expertise can constitute a center for the hepatitis elimination process. Addressing both HCV and opioid overdoses is essential in reducing morbidity and mortality in this high-risk population.

EFFICACY OF VELPATASVIR AND SOFOSBUVIR COMBINATION THERAPY IN CHRONIC HCV PATIENTS.

Hafiz Ather
1Faisalabad Med University Faisalabad Pakistan

Authors. Professor Dr Hafiz Mughees Ather, Dr Arfan Mahmood , Dr Umair Waheed , Dr Mohammed Osama, Dr Aflan Shahid.

Abstract:
Introduction: Chronic Hepatitis C is a prevalent infection in Pakistan. It can lead to complications like cirrhosis of liver, liver failure, hepatocellular carcinoma and death. Oral antiviral therapy has revolutionized the treatment of Hepatitis C. It can achieve eradication of HCV in the form of sustained virological response in HCV patients. We conducted a study to analyze the efficacy of Sofosbuvir, Velpatasvir combination therapy with Ribavirin except when there was a contraindication.

Materials and methods: It was a prospective single cohort study including all chronic Hepatitis C patients who underwent treatment for Chronic hepatitis C virus (HCV) with Sofosbuvir (SOF) and Velpatasvir (VELPA) combination therapy with Ribavirin. All patients were more than 18 years old.

Results: 64% patients were males and 36% were females. 6.1% patients were cirrhotic and all patients received Ribavirin. SVR was achieved in 111/114 (97.36%) patients.
Conclusion: Sofosbuvir, Velpatasvir combination therapy with Ribavirin is an effective antiviral therapy for the treatment of chronic hepatitis C.

Key Words: Hepatitis C, Sofosbuvir, Velpatasvir, Ribavirin, Naive, HCV Treatment in Faisalabad, Cirrhosis, Sustained Virological Responses

CHANGES IN THE DEGREE OF LIVER STEATOSIS AND LIPID PROFILE OF HEPATITIS C PATIENTS AT SVR12

Putra Nur Hidayat1,2, Cosmas Rinaldi Adithya Lesmana3, Chyntia Olivia Maurine Jasirwan3, Andri Sanitosyo Sulaiman1, Siti Setiati4, Aulia Rizka4, Adityo Susilo5
1RSCM FKUI Jakarta Indonesia, 2Department of Internal Medicine, Faculty of Medicine, Universitas Indonesia/Dr. Cipto Mangunkusumo 7 Hospital, Jakarta Jakarta Indonesia, 3Hepatobiliary Division, Department of Internal Medicine, Faculty of Medicine, Universitas Indonesia/Dr. 9 Cipto Mangunkusumo Hospital, Jakarta Jakarta Indonesia, 4Geriatrics Division, Department of Internal Medicine, Faculty of Medicine, Universitas Indonesia/Dr. Cipto 11 Mangunkusumo Hospital, Jakarta Jakarta Indonesia, 5Tropical and Infectious Disease Division, Department of Internal Medicine, Faculty of Medicine, Universitas 13 Indonesia/Dr. Cipto Mangunkusumo Hospital, Jakarta Jakarta Indonesia

Background: The relationship between hepatitis C patients’ SVR12 incidence, lipid profile, and liver steatosis remains unclear. The results of existing publications are still inconsistent regarding changes in the value of these parameters after SVR12. This study aims to examine changes in the degree of hepatic steatosis and lipid profile in hepatitis C patients during SVR12 and look for their relationship.

Methods: Longitudinal design, before and after a study conducted at Cipto Mangunkusumo Hospital (RSCM). The study was conducted for one year. Patients who met the inclusion criteria were included and examined for lipid profile and controlled attenuated parameter values before and after therapy.

Results: The mean SD CAP value increased before therapy 196±49.36 dB/m and after therapy 227±47.11 dB/m. There is significant increase in mean SD value of total cholesterol (166±40.30 mg/dL vs 190±42.58 mg/dL), triglycerides (94±45.39 mg/dL vs 109±49.83 mg/dL), and LDL (109.48±39.57 mg/dL vs 130.88±34.32 mg/dL). There was a negative correlation between CAP values in hepatitis C patients before therapy and changes in CAP values after DAA therapy. No correlation exists between changes in total cholesterol, HDL cholesterol, LDL cholesterol, and triglycerides with the degree of liver steatosis at SVR12.

Conclusion: There is a difference in the degree of liver steatosis, total cholesterol, HDL cholesterol, LDL cholesterol, and triglyceride levels before therapy and at SVR12 in hepatitis C patients receiving DAA therapy. There was negative correlation between CAP values at baseline and SVR12

Characteristics of Hepatitis C Patients Undergoing Oral Antiviral Therapy at Our Institution

Atsuhiro Morita1, Kohji Uno1, Naonori Inoue1
1Japanese Red Cross Society, Kyoto Daini Red Cross Hospital Kyoto City Japan

Background and Aims: Direct acting antiviral therapy (DAA) has shown high efficacy for HCV infection. However, untreated cases of chronic hepatitis C remain a domestic problem. This study analyzes treatment outcomes and patient characteristics during different time periods, aiming to identify issues in acquiring untreated patients and improve acquisition strategies.

Methods: 257 DAA cases (Oct 2015 - Sep 2023) were categorized into early (2015-2017) and later periods (2018-2023) with glecaprevir/pibrentasvir. We examined factors such as consultation reasons, efficacy, follow-up, prognosis, and mortality causes. Collaboration between our institution and regional healthcare facilities in DAA therapy cases was investigated.

Results: Of 257 cases, 149 were in the early period, and 108 in the later period. Median ages were 68 and 69.5, with male: female ratios of 71:78 and 43:65. Genotypes 1, 2, and others were 105/44:0 and 68:38:2 in early and later periods. SVR rates were 99.3% and 100%. Cases under treatment versus referrals were 96:53 and 60:48. Liver disease-related deaths were 1/5 for both periods, with 12 and 4 lost to follow-up cases. 101 referrals came from various healthcare institutions, with 1-4 patients per facility (median: 1).
Discussion: Around 40% of DAA cases were referred, 53.6% in the early and 48.8% in the later period. DAA therapy showed high SVR and survival rates, with a low lost-to-follow-up rate, emphasizing the importance of regional collaboration.

Conclusion: Enhancing collaboration with regional healthcare institutions and strengthening intra-institutional coordination is crucial. Efforts should be made to expand DAA therapy to more chronic hepatitis C patients.

Concurrent Management of Chronic Hepatitis C and Advanced Hepatocellular Carcinoma: A Case Report

Rene John Febro1, Engelbert Simon Perillo1, Jaqueline Arsenal1, Salahuddin Andam1, Maria Hossea Montero1, Erika Johanna Tanada1, Hyacinth Maurille Van Eviota1, Stephen Wong1
1University of Santo Tomas Hospital Manila Philippines

There is paucity of data concerning the concurrent management of patients with active Hepatitis C virus (HCV) infection and hepatocellular carcinoma (HCC). Guidelines regarding the timing and duration of HCV treatment in patients with advanced HCC are still ill-defined. We present a case of advanced HCC with concomitant HCV infection who was successfully downstaged following immunotherapy and direct-acting antiviral treatment. A 71-year-old Filipino male was referred for evaluation of recently diagnosed HCV infection and liver mass. Dynamic imaging showed infiltrative mass at the right hepatic lobe with portal vein thrombosis (PVT). He received concurrent treatment with sofosbuvir-velpatasvir and atezolizumab-bevacizumab. Sustained virologic response 12 weeks post-treatment was achieved. Radiologic evaluation revealed a significant decrease in tumor size. Patient underwent successful curative microwave ablation and is currently tumor and drug-free for 21 months. Our case shows that patients with advanced HCC and HCV infection may attain excellent responses with simultaneous treatment. Data from prospective, randomized-controlled trials are needed to identify patients who will benefit most from this strategy.

Nomogram for Predicting Hepatocellular Carcinoma in HCV-associated Cirrhosis Patients

xuemei tao1, liang xu1, yuqi yang mi1, jing zhang2
1Tianjin Second People's Hospital of Tianjin Medical University Tianjin China, 2Youan Hospital of Capital Medical University Beijing China

Background and objectives: Hepatitis C virus (HCV) associated cirrhosis are in high risk of hepatocellular carcinoma (HCC), and this study aimed to explore the risk factors, and establish and validate a novel nomogram.

Methods: A total of 309 inpatients with HCV-associated cirrhosis from Tianjin Second People’s Hospital were selected as the training cohort, and 363 patients from Beijing You’an Hospital were selected as the validation cohort. Both cohorts received Direct-Acting Antiviral Agents (DAAs) treatment and achieved sustained virological response (SVR). Laboratory parameters were collected at baseline and duration of follow-up. Cox regression analysis was used to explore risk factors of HCC, and a nomogram for prediction was developed and validated.

Results: HCC incidence was 5.45 100PY (95% CI, 3.91-7.40) in patients of the training cohort. Age, nonspecific liver nodules, the albumin-Bilirubin (ALBI) score and end of treatment (EOT)-AFP are independent risk factors for HCC by Cox regression analysis. A nomogram was used to predict the 1-year, 3-year and 5-year incidence of HCC, with the areas under receiver operating characteristic curves (AUROCs) of 0.866, 0.813 and 0.764, respectively. The AUROCs in validation cohort at 1, 3, and 5 years were 0.884, 0.783 and 0.692 in this nomogram, respectively.

Conclusion: This novel nomogram had a good predictive ability for HCC in patients with HCV-associated cirrhosis after eliminating virus with direct-acting antiviral agents, especially in 3 years.

Abstract Submission No. 200091

Objective: To prospectively observe hepatocarcinogenesis in hepatitis C patients treated with DAA and to examine the relationship between fibrosis remission and carcinogenesis.

Methods: A prospective observational study was conducted on hepatitis C patients treated with DAA from July 2013 to November 2023. The primary endpoint was the occurrence of liver cancer, and the secondary endpoint was the change in liver stiffness. Liver stiffness was measured by Fibro-scanner and divided into 4 groups (Group 1: <4 kPa, Group 2: 4 to 8 kPa, Group 3: 8 to 12 kPa, Group 4: 12 kPa or higher). The most improved values before and after DAA were compared.

Results: All 689 patients were prospectively observed. The median observation period was 6.0 years. During the observation period, hepatocellular carcinoma occurred in 70 patients (10%). Liver stiffness trends were group 1 (1-1 80%, 1-2 20%), group 2 (2-1 14%, 2-2 84%, 2-3 1%, 2-4 1%), group 3 (3-1 13%, 3-2 50%, 3-3 30%, 3-4 1%), and group 4 (4-14%, 4-2 24%, 4-3 20% 4-4 52%). The incidence of liver cancer was group 1 (1-1 0%, 1-2 0%), group 2 (2-1 14%, 2-2 84%, 2-3 0%, 2-4 50%), group 3 (3-1 5%, 3-2 30%, 3-3 12.5%, 3-4 50%) and group 4 (4-1 28.6%, 4-2 15.2%, 4-3 30%, 4-4 25.5%). Up to group 3, the incidence of liver cancer tended to be low as fibrosis remitted, but in group 4, the incidence was high even when fibrosis remitted.

Conclusion: Patients with high liver stiffness before DAA treatment should be aware of the risk of carcinogenesis even after fibrosis remission.

VIETNarms: A strategic post-licensing randomised trial of direct acting Hepatitis C antivirals
Feng Ren1, Xiangying Zhang1, Yuan Tian2, Zhihao Fan2, Ling Xu2, Hong Zhang3, Ten Tang4, Yuming Li5, Leanne McCabe3, Barney Flower1, for SEARCH collaborators2

1Imperial College London United Kingdom, 2OUCRU Ho Chi Minh City Vietnam, 3MRC Clinical Trials Unit, UCL London United Kingdom, 4University of Oxford United Kingdom, 5Hospital for Tropical Diseases Ho Chi Minh City Vietnam, National Hospital for Tropical Diseases Hanoi Vietnam

Background: No randomised trials have compared WHO-recommended first-line hepatitis C treatments. More evidence is needed to support therapeutic strategies to deliver expanded treatment access.

Methods: We enrolled adults with chronic hepatitis C infection without evidence of significant liver disease (Fibroscan<9.0kPa) from two centres in Vietnam (Ho Chi Minh City, Hanoi). Patients were stratified into genotype-6/non-genotype-6 and randomly allocated to one of two treatment strategies (i) standard-of-care 12 weeks (SOC) (ii) four weeks DAA therapy with 4 weeks Pegylated interferon (PEG-IFN) doses from week-3 (iii) induction/maintenance therapy with two weeks standard therapy followed by 10 weeks therapy 5 days/week and (iv) response-guided therapy of 4, 8 or 12 weeks determined by viral load on day-7 of treatment. Primary outcome was sustained virological response 12 weeks after treatment completion (SVR12).

Results: Primary outcome data were available for 644 of 646 randomised participants. 296(47%) were genotype-6; 328(53%) non-genotype 6 were mostly genotype-1/2. Overall SVR12 was 294(302)(97%) for SOF/DCV and 292(307)(95%) for SOF/VEL combinations. SVR12 for strategies were (i) 148/150(99%) in SOC (ii) 143/152(94%) with 4 weeks Peg-IFN (iii) 151/152(99%) with induction/maintenance and (iv) 144/153(93%) with response-guided therapy. Overall severe adverse events were rare (3%) with no significant differences between treatment combinations or strategies.

Conclusions: High efficacy rates were achieved for both sofosbuvir/daclatasvir and sofosbuvir/velpatasvir as well as three different strategies that may be suitable to improve access for harder-to-reach treatment populations.

CRISPR/Cas13a-Assisted Accurate and Portable Hepatitis D Virus RNA Detection
Feng Ren1, Xiangying Zhang1, Yuan Tian2, Zhihao Fan2, Ling Xu2, Yao Gao3, Yining Cao1, Zhenzhen Pan1

1Beijing Youan Hospital, CMU Beijing China

Background & Aims: Hepatitis delta virus (HDV) infection accelerates the progression of chronic hepatitis B virus (HBV) infection, posing a large economic and health burden to patients. At present, there remains a lack of accurate and portable detection methods for HDV RNA. Here, we aim to establish a convenient, rapid, highly sensitive and specific method to detect HDV RNA using CRISPR–Cas13a technology.

Methods: we established fluorescence (F) and lateral flow strip (L) assays based on CRISPR–Cas13a combined with RT–PCR and RT–RAA, respectively. we conducted a cohort study of 144 patients with HDV-IgG positive to evaluate the CRISPR–Cas13a diagnostic performance for identifying HDV in clinical samples, compared to RT–qPCR and RT-ddPCR.

Results: For synthetic HDV RNA plasmids, the sensitivity of RT–PCR-CRISPR-based fluorescence assays was 1 copy/μL, higher than that of RT–qPCR (10 copies/μL) and RT-ddPCR (10 copies/μL); for HDV RNA-positive samples, the sensitivity of RT-RAA-CRISPR-based fluorescence and lateral flow strip assays was 10 copies/μL, as low as that of RT–qPCR and RT-ddPCR, and the assay took only approximately 85 minutes. Additionally, the positivity rates of anti-HDV IgG-positive samples detected by the RT–qPCR, RT-ddPCR, RT–PCR-CRISPR fluorescence and RT-RAA-CRISPR lateral flow strip methods were 66.7% (96/144), 76.4% (110/144), 81.9% (118/144), and 72.2% (104/144), respectively.

Conclusions: We developed a highly sensitive and specific, as well as a portable and easy CRISPR-based assay for the detection of HDV RNA, which could be a prospective measure for monitoring the development of HDV infection and evaluating the therapeutic effect.

Hepatitis Delta Virus Testing and Prevalence Among Veterans with Chronic Hepatitis B in the USA
Robert Wong1, Zeyuan Yang1, Janice Jou2, Binu John3, Joseph Lim1, Ramsey Cheung1

1Stanford University School of Medicine/VA Palo Alto Healthcare System Palo Alto United States, 2Oregon Health & Science University Hospital, Portland VA Medical Center Portland USA, 3University of Miami Miller School of Medicine, Miami VA Medical System Miami USA, 4Yale University School of Medicine New Haven USA

Background: Poor awareness of hepatitis delta virus (HDV) contributes to suboptimal testing, delayed diagnosis, and increased morbidity/mortality. We aim to evaluate HDV testing patterns and HDV prevalence among a national cohort of United States (US) Veterans with chronic hepatitis B (CHB).

Methods: Using longitudinal data on all Veterans receiving care within Veteran health systems (1/1/2010-9/30/2023), HDV testing (HDV antibody, HDV RNA, HDV antigen) among CHB patients, and the proportion positive among those tested, were compared using chi-square methods. Multivariable logistic regression models evaluated predictors of HDV testing (entire CHB cohort) and HDV test positive (among those tested).

Results: Among 27,548 CHB patients (93.2% male, 92.5% non-Asian, 2.8% HIV, 22.3% HCV, 32.8% drug use, 10.5% cirrhosis), 16.1% completed HDV testing and 3.25% were positive. HDV testing was higher among Asians vs. non-Hispanic white (29.0% vs. 14.9%, aOR 1.94, 95%CI 1.32-1.68), men vs. women (16.2% vs. 14.5%, aOR 1.24, 95%CI 1.07-1.43), and HIV positive vs. negative (17.8% vs. 16.1%, aOR 1.32, 95%CI 1.07-1.64), p<0.01 for all. Among those tested, HDV positive was higher in HCV-positive vs. HCV-negative (8.45% vs. 2.35%, aOR 3.24, 95%CI 1.94-5.42), cirrhosis vs. non-cirrhosis (7.71% vs. 2.80%, aOR 2.27, 95%CI 1.47-3.53), and drug use vs. non-drug use (5.30% vs. 2.49%, aOR 2.04, 95%CI 1.14-3.63), p<0.01 for all.

Conclusion: Among US Veterans with CHB, HDV testing is alarmingly low, particularly among patients with HDV risk factors. HDV test positive was highest in patients with cirrhosis, HCV, and drug use. Greater HDV awareness is needed to improve timely diagnosis and treatment.

Bulevirtide improves virologic & biochemical response in non or partial responders with CHD

Pietro Lampertico1, Heiner Wedemeyer2, Maurizia R. Brunetto1, Mark Bourlière4, Dmitry Manuilov5, Qi An1, Audrey H. Lau3, Ben L. Da5, Renee-Claude Mercier3, Stefan Zeuzem6, Markus Cornberg2, Dominique Roulot2, Fabien Zoulim7, Soo Aleman8, Tarik Asselah9

1Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico Milan Italy, 2Medizinische Hochschule Hannover Hannover Germany, 3Hepatology Unit, University Hospital of Pisa Pisa Italy, 4Hôpital Saint Joseph Marseille France, 5Gilead Sciences, Inc. Foster City, CA United States, 6Frankfurt University Hospital Frankfurt am Main Germany, 7Université Sorbonne Paris Nord Bobigny France, 8Hôpital de la Croix-Rousse Lyon France, 9Karolinska University Hospital/Karolinska Institutet Stockholm Sweden, 10Hôpital Beaujon, Université de Paris Cléchy France

Background: Bulevirtide (BLV) is approved in Europe for chronic hepatitis delta (CHD). It’s unclear whether BLV monotherapy benefits patients with early virologic nonresponse (NR) or partial response (PR) after 24 weeks (Wks).

Methods: Patients completed 96-Wk BLV monotherapy. Virologic response (VR) was defined as undetectable hepatitis delta virus (HDV) RNA or ≥2 log10 IU/mL decline from baseline (BL); NR and PR were defined as HDV RNA declines of <1 log10 IU/mL and ≥1 but <2 log10 IU/mL, respectively. Biochemical responses (alanine aminotransferase [ALT] within normal limits [WNL]) were compared.

Results: At Wk24, 92/141 patients had VR (ALT WNL, 53), 34/141 had PR (ALT WNL, 19), and 15/141 had NR (ALT WNL, 2) (Table). Of the 34 PR patients at Wk24, 25/35 PR patients had VR and 24 had ALT WNL by Wk96. Of the 15 NR patients at Wk24, 7 had VR and 3 had PR by Wk96. More NR at Wk24 achieved VR at Wk96 with BLV 10mg [4/5] vs BLV 2mg [3/10]. Median BL ALT was higher in patients with NR and PR at Wk96. The mean (SD) log10 IU/mL HDV RNA change at Wk96 among VR/PR/NR was −3.6 (1.1), −1.4 (0.3), and −0.2 (0.7) for VR, PR, and NR at Wk96. Median (Q1, Q3)ALT (U/L) change at Wk96 among VR/PR/NR was −48 (−73, −12), −42 (−83, −6), and −67 (−102, −33). Among NR at Wk96, ALT declined >50% from BL in 7/11 patients.

Conclusion: Results support continued BLV monotherapy despite early suboptimal virologic responses.

Efficacy & safety of bulevirtide in combination with pegylated interferon α-2a in patients with CHD

Tarik Asselah1, Pietro Lampertico2, Heiner Wedemeyer3, Adrian Streinu-Cercel4, Victor Pantea5, Stefan Lazar4, Gheorghe Placinta2, Vladimir Chulanov2, Dmitry Manuilov3, Renée-Claude Mercier3, Lei Ye6, Audrey H. Lau3, Stanislas Pol7, Fabien Zoulim8

1Hôpital Beaujon, Université de Paris Cléchy France, 2Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico Milan Italy, 3Medizinische Hochschule Hannover Hannover Germany, 4Matei Balșy National Institute of Infectious Diseases Bucharest Romania, 5Infectious Clinical Hospital “T. Ciorbă” Chișinău Moldova, 6Dr. Victor Babes Foundation, Infectious and Tropical Diseases Hospital Bucharest Romania, 7National Medical Research Center for Phthisiopulmonology and Infectious Diseases Moscow Russian Federation, 8Gilead Sciences Inc. Foster City, CA United States, 9Hôpital Cochin Paris France, 10Hôpital de la Croix-Rousse Lyon France

Background: Bulevirtide (BLV) is approved for chronic hepatitis delta (CHD). Phase 2 MYR204 evaluated the safety and efficacy of BLV (2 and 10mg) with/without pegylated interferon α-2a (pegIFN) in patients with CHD and compensated cirrhosis (CC).

Methods: Based on CC status, 174 patients were randomized (1:2:2:2) to receive (A) pegIFN for 48 weeks (Wks); (B) BLV 2mg + pegIFN; (C) BLV 10mg + pegIFN for 48 Wks, then BLV 2 or 10mg monotherapy for 48 Wks; or (D) BLV 10mg for 96 Wks. The primary endpoint was sustained virologic response (SVR) at Wk24 (SVR24) after EOT (end of treatment) defined as undetectable hepatitis delta virus (HDV) RNA with comparison between Arms C and D.

Results: Overall, 35% had CC, mean liver stiffness was 13.1 (7.2) kPa, mean HDV RNA was 5.3 (1.2) log10 IU/mL, mean alanine aminotransferase (ALT) was 114.0 (94.8) U/L, 28% were on nucleos(t)ide analogue therapy, and 48% were IFN experienced. SVR24 was achieved by 17% (Arm A), 30% (Arm B), 46% (Arm C), and 12% (Arm D) (P = 0.0003; Arm C vs D) (Table). ALT normalization and composite endpoint at Wk24 after EOT were superior with BLV 10mg + pegIFN vs monotherapy. Hepatitis B surface antigen loss was observed in the combination groups. Adverse events (AEs) observed for the BLV + pegIFN arms were similar to pegIFN monotherapy. Six patients (3%) discontinued treatment (unrelated to BLV).

Conclusions: Combination therapy was effective and well tolerated. Longer-term data will help define durability of BLV + pegIFN for CHD.

M.F. Vladimirsky Moscow Regional Research and Clinical Institute; I.M.Sechenov First Moscow State Medical University; A.I.Yevdokimov Moscow State University of Medicine and Dentistry; “Center for targeted therapy”, Moscow, Russia, “Department of Viral hepatitis of the A.M.Magomedov Republican Center for Infectious Diseases, Prevention and Control of AIDS Makhachkala Russia

We analyzed retrospective data from 61 chronic hepatitis D (CHD) patients, including 27 with compensated cirrhosis, treated with bulevirtide, HBV and HDV entry inhibitor, 2 mg/day sc as
monotherapy or dual therapy (combined with peginterferon) up to 144 weeks in Moscow region and Dagestan centers. A 48-week treatment resulted in a significant decrease in HDV RNA levels from 6.9 log to undetectable (p<0.001), median reduction in HDV RNA levels from baseline -5.0 log, monotherapy -4.0 log, dual therapy -5.7 log, alanine aminotransferase (ALT) levels - from 68.0 to 31.0 U/l (p<0.001), high virological response rate (95%), monotherapy 93%, dual therapy 96%, full virological response (aviremia) 58%, ALT normalization (69% vs 20% at baseline). Virolological efficacy improved over the course of treatment. In patients with compensated cirrhosis similar virological response dynamics were observed compared to the overall group. The treatment was well tolerated, without serious adverse events, cases of treatment withdrawal. CHD treatment with bulevirtide in real-world practice demonstrated high efficacy, safety and good tolerability, including patients with compensated cirrhosis. Further development of an optimal treatment algorithm is needed.

Compassionate use of REP 2139-Mg in HBV/HDV infection with advanced liver disease
Andrew Vaillant1
1Replicor Inc. Montreal Canada

Background: In fibrotic patients, REP 2139-based combination therapy achieves high rates of functional cure of HBV and HDV. An ongoing compassionate use program (NCT05683548) provides REP 2139-Mg therapy for cirrhotic HBV / HDV co-infection with viral nonresponse or rebound with pegIFN and or bulevirtide therapy.

Methods: Add-on therapy with 250mg REP 2139-Mg qW SC and 90ug pegIFN (with compensated cirrhosis) was scheduled for 48 weeks. Safety and biochemical response were monitored weekly and virologic response every 4 weeks using standard assays for quantitative HBsAg and anti-HBs, HBV DNA, HDV RNA, HIV RNA and HBeAg.

Results: Currently 27/32 patients have completed > 24 weeks of REP 2139-Mg therapy. Transient grade 1 injection site reactions occur in a majority of patients. Four ALT flares > 5 U/L occurred accompanied pegIFN; 3 self-resolving and one resolved after removal of pegIFN. ALT has normalized in 12/32 patients.

HDV RNA has declined > 2 log, from baseline (22/32) and HDV RNA loss (15/32) is accompanied by HBsAg decline > 2 log (12/32), HBeAg loss (6/32) and anti-HBs seroconversion (6/32). HDV clearance was observed in 1 liver explant after 10 weeks of therapy. Functional cure of HBV with HDV cure (n=1) and persistent HBsAg and HDV RNA loss on TDF monotherapy (n=2) have occurred after removal of REP 2139-Mg.

Conclusions: REP 2139-Mg is safe and effective against HBV/HDV infection in advanced liver disease. REP 2139-Mg can clear HDV RNA from the blood and liver and can establish HBV functional cure and HDV cure in advanced liver disease.

High prevalence of Hepatitis D by double reflex testing of HBsAg positive individuals in Pakistan
Minaam Abbas1, Zaigham Abbas2
1Department of Medicine, University of Cambridge1 West Suffolk Hospital Cambridge United Kingdom, 2Dr. Ziauddin University Hospital, Clifton Karachi Pakistan

Background: Hepatitis D caused by the hepatitis delta virus (HDV) is a serious health problem in many regions of the world. We aimed to determine the prevalence of HDV infection by double reflex testing on HBsAg-positive visitors of screening camps in Usta Muhammad and Dera Allah Yar, two high-prevalence neighbouring towns in the eastern part of Baluchistan province of Pakistan.

Methods: 1643 people were examined for HBsAg and anti-HCV antibodies using ICT methods. HBsAg-positive individuals were further tested for antibodies to HDV (anti-HDV) using enzyme immunoassay (EIA). Samples with detectable anti-HDV were further examined for HDV RNA using real-time PCR.

Results: Of the 1643 individuals examined, HBsAg was reactive in 277 (16.9%) individuals. The reflex test for anti-HDV antibodies of these HBsAg positives was positive in 186 (67.1%); 133 were men and 53 were women. The mean age (years) was 32.2±11.3. HDV RNA was detectable in 108 (58.1%) of the anti-HDV-reactive patients. Log10 HDV RNA levels (IU/ml) were 6.69±1.34. Anti-HCV was detected in 227 (13.8%) of all examined individuals. Of these, four anti-HCV-positive individuals were also positive for HBsAg and one was positive for anti-HCV, HBsAg, and anti-HDV but negative for HDV RNA.

Conclusions: Reflex testing of HBsAg-positive individuals for HDV in an endemic area revealed that 67% of HBsAg-positive individuals had HDV exposure and 58.1% of anti-HDV-positive individuals had HDV viremia. Our study highlights the need for double-reflex testing in HBsAg-positive individuals for anti-HDV antibodies and HDV RNA in anti-HDV-positive individuals.

Development of a network for hepatitis D registration and study in Taiwan: TADR - An update in 2023
Tsung-Hui Hu1, Chun-Jen Liu1, Shiu-Feng Huang2, Ming-Lung Yu1, Chi-Yi Chen1, Chao-Wei Hsu1, Cheng-Yuan Peng1, Pin-Nan Cheng1, Yi-Hsiang Huang3, Chih-Lin Lin1, Chia-Chi Wang1, Teng-Yu Lee1, Hsing-Tao Kuo1, Yao-Chun Hsu1, Pei-Jer Chen1,3
1Taiwan Association for the Study of the Liver (TASL) Taipei Taiwan, 2National Institute of Cancer Research, National Health Research Institutes Miaoli Taiwan, 3Division of Gastroenterology and Hepatology, Department of Internal Medicine, National Taiwan University Hospital Taipei Taiwan

Backgrounds: HBV and hepatitis delta (HDV) dual infections lead to more severe liver disease, with increased rates of cirrhosis and hepatic decompensation, and hepatocellular carcinoma (HCC). We aim to establish a nationwide epidemiological study of HDV in Taiwan.

Methods: We follow the successful launching of TACR (TASL Hepatitis C Registration) in Taiwan and invite the corresponding medical centers to join TADR (TASL Hepatitis D registration). TADR use this existing platform and to set up and manage the platform and blood samples of HDV patients (hospital cohort). A community cohort and special population (HIV/HBV co-infection) cohort will be also included for comparison. TADR already kicked off in February 2022, and includes 14 medical centers so far.

Results: At the end of OCT 2023, there have been 318 HDV cases registered. The prevalence of HDV in hospital cohort is approximately 1.2%. In a subgroup analysis of HBV related cirrhotic patients undergoing nucleos(t)ide therapy (NCT), the prevalence of HDV infection is 1.79% (14/780). There is no significant association between HDV and baseline clinical characteristics of patients (except age), as well as
the development of HCC and survival during follow up. Furthermore, a HDV surveillance in HBV related HCC patients was conducted from Taiwan Liver Cancer Network (TLCN). Among the 4217 patients, the prevalence of HDV is 2.75% (116/4217). HBV-HDV dual infected patients displayed worse 5-year survival than that of HBV mono-infection.

Conclusions: The changing HDV landscape in Taiwan will be refined. A case-controlled study might be mandatory in the future.

Efficacy of Pegylated Interferon-Alpha-2a in HDV: Experience from the Tertiary Care Hospital.

Riaz Hussain1, Nazish Butt1, Mohammad Masood1, Aman Ullah2
1Jinnah Postgraduate Medical Centre, Karachi, Pakistan, 2Civil Hospital Karachi KARACHI Pakistan

Objective: To evaluate the efficacy of Pegylated Interferon-Alpha-2a in chronic hepatitis D (CHD) infected patients presenting at a tertiary care hospital, in Karachi.

Methods: We have enrolled a total of 165 (CHD) patients at the Gastroenterology section of medical unit IV, Jinnah Postgraduate Medical Centre, Karachi, Pakistan, from July 2017-Oct 2023 who were treated for 48 weeks with Pegylated Interferon-Alphander A. Evaluation of HDV infection through Polymerase chain reaction (PCR) was done at 24 weeks, and 48 weeks interval. All laboratory values were repeated at regular intervals to assess the efficacy and side effects of therapy. Baseline and clinical data were recorded in a pre-structured questionnaire and analyzed using a statistical package for the social sciences (SPSS) version 21.0.

Results: A total of 148 patients were enrolled in the study, and final analysis was performed on 148 patients, among all, more than n = 76 (50.66%) of the patients had treatment failure response. While around n = 42 (28%) of the patients had partial treatment response and only n = 32 (21.33%) had treatment success rate. There was an insignificant difference observed when treatment response was compared among patients who received treatment at 24 weeks and 48 weeks (p<0.05). Alanine aminotransferase and total bilirubin levels were significantly improved in patients who achieved partial and end treatment with a mean difference of 7.69±2.5 and 0.33±0.24, (p<0.05), respectively.

Conclusion: Pegylated Interferon-Alpha-2a therapy in patients with CHD shows a sub-optimal outcome of (21.33%). Patients with treatment failure or null response required effective alternate therapy.

Clinical profile of patients with chronic HDV infection by the nationwide Italian PITER-cohort

Loreta A Kondili1, PITER Collaborating Investigators (www.progettopiter.it)1, Giuseppina Brancaccio1, Maria Elena Tosti1, Barbara Coco1, Maria Giovanna Quaranta1, Vincenzo Messina2, Alessia Ciancio3, Filomena Morisco4, Valerio Rosato1, Marianna Ciarello1, Irene Cacciola1, Maurizia Rossana Brunetto2, Giovanni Battista Gaeta2
1Center for Global Health, Istituto Superiore di Sanità Rome Italy, 2Infectious Disease Unit, University L. Vanvitelli Naples Italy, 3Department of Molecular Medicine, Infectious Diseases, University of Padua Padua Italy, 4University Hospital of Pisa Pisa Italy

Background and Aims: We aimed to comprehensively characterize patients with chronic hepatitis D (CHD) and explore treatment eligibility and prioritization criteria.

Methods: In this multicenter, cross-sectional cohort study, hepatitis B surface antigen (HBsAg)-positive patients were enrolled from 59 centers across Italy from November 2019 to February 2023. Multivariate logistic regression models explored the association between the considered variables with hepatitis D virus (HDV)-ribonucleic acid (RNA) positivity or liver cirrhosis.

Results: Of 4,152 enrolled patients, 422 (10.16%) were anti-HDV positive. Patients with anti-HDV were younger, more frequently non-Italian native, with a history of injection drug use, elevated ALT, and the presence of cirrhosis or hepatocellular carcinoma (HCC). Non-Italians were younger (42% aged <42 vs. 21%; p<0.001) and more frequently female (68.6% vs. 43.0%; p<0.001). Cirrhosis and HCC were more frequent among Italian patients. HDV-RNA was detected in 63% of tested patients who were likelier to have elevated ALT or gamma GT values, cirrhosis, and HCC. Body mass index (BMI)>25 was more frequent among HDV-RNA-negative patients. In the multivariable Cox model, only ALT was associated with HDV-RNA presence (OR 12.9, CI 95%: 6.3-26.3). Comorbidities were diagnosed in 47% of anti-HDV-positive patients; comorbidities were independently associated with cirrhosis, together with age and male gender. Based on absolute or relative contraindications, 22% of patients were eligible for IFN-based therapies.

Conclusions: CHD affects young foreign-born patients and older Italians, of whom two-thirds had cirrhosis or HCC. Comorbidities were associated with cirrhosis, and their role in liver disease progression should be further explored.

Abstract Submission No. 101793
O-0253

HCC risk is similar in HDV patients with viral response to treatment compared to HBV patients

Cihan Yurdaydn1-2, Onur Keskin3, Muge Ozari3, Genco Gençdal1, Ramazan İldim1, Mujdat Zeybel1, MURat Akyıldız1
1Kȯtetep University Ankara Turkey, 2Hacettepe University Ankara Turkey, 3Ankara University Ankara Turkey

Meta-analyses reported increased HCC risk in chronic hepatitis D (CHD) vs. chronic hepatitis B (CHB) (Alfawi et al, 2020, Kamal et al, 2021). Aim of this study was to compare effect of treatment on HCC development in CHD vs CHB.

Methods: 124 CHD patients (88male; mean age: 40.3±10.3, 28 [23%] cirrhotic at baseline) received a median 2 years (6 to 126 months) of interferon. 242 CHB patients (166M; mean age: 48.5±12.7, 65 [27%] cirrhotic) treated with entecavir or tenofovir were included. >95% of CHB. and 32% (40/124) of CHD patients had viral response (VR).

Results: Two groups were similar for baseline characteristics except for age (48.5±12.7 vs 40.3±10.3; p<0.01), HBeAg positivity (32.6% vs 16.9% p<0.01), platelets (188.5±76.7 vs 162±55.6; p<0.01) and ALT (80.2±113.4 vs 103.7±101.7; p=0.05) for CHB and CHD, respectively. HCC developed in 23 (9.5%) of CHB and in 21 (16.9%) of CHD patients during median 8 years of follow-up (FU). Cumulative HCC
Lonafarnib-based regimens associated with long-term apparent cures in chronic hepatitis delta

Cihan Yurdaydın1,2, Muge Ozari3, Onur Keskin4,5, Genco Gençdal5, Ramazan Idilman2, Mithat A Bozdaly2, Jeffrey S Glenn6

1Ko_OPERATION from Istanbul Turkey, 2Ankara University Ankara Turkey, 3Hacettepe University Ankara Turkey, 4Stanford University Stanford, CA USA, 5Veterans Administration Palo Alto, CA USA

The farnesyl transferase inhibitor lonafarnib is in advanced clinical development for chronic hepatitis delta virus (HDV) infection, having been studied in multiple phase 2 and 3 studies. Several patients who participated in these studies have now been followed for over eight years following clearance of HDV RNA and ALT. Here we report on four patients who following a single, or one brief retreatment, course of LNF-based therapy of 3 to 12 months duration demonstrated off-treatment virologic and biochemical responses lasting beyond 5 years of treatment discontinuation. In 3 of the 4 patients, long-term off-treatment efficacy was induced after a post-treatment beneficial enzymatic flare leading to regression of liver fibrosis while in one patient HDV RNA negativity was achieved on-treatment. One patient also cleared HBsAg. In 2 additional patients quantitative HBsAg levels at last visit were below 100 IU/mL. In conclusion, lonafarnib-based treatment appears to be an option for finite treatment in CHD where post-treatment virologic and biochemical responses lasting beyond 5 years following clearance of HDV RNA and ALT. Here we report on four patients who participated in these studies have now been followed for over eight years following clearance of HDV RNA and ALT. One patient also cleared HBsAg. In 2 additional patients quantitative HBsAg levels at last visit were below 100 IU/mL. In conclusion, lonafarnib-based treatment appears to be an option for finite treatment in CHD where post-treatment viral response may be at least as important as end of treatment rates in CHB and CHD patients with VR.

Pegylated Interferon α for patients with chronic hepatitis D in Mongolia

Sainzaya Batmunkh1, Sarantuya Gidaagaya1, Munkhbat Batmunkh2,3, Bira Namdag4

1Mongolia Japan hospital, Mongolian National University of Medical Sciences Ulaanbaatar Mongolia, 2Department of Medical Law and Education, Graduate school, MNUMS, Mongolia Ulaanbaatar Mongolia, 3Department of Public Health, School of Medicine, IUIW, Japan Tokyo Japan

Introduction: Mongolia faces a high prevalence of chronic viral hepatitis, contributing to severe liver diseases like cirrhosis and hepatocellular carcinoma. This retrospective study analyzes the response rate of chronic hepatitis delta (CHD) patients treated with pegylated Interferon alpha (peg-IFNα).

Materials and Methods: Thirty-six CHD patients (mean age 37.4; male: 63.9%) receiving at least 24 weeks of peg-IFNα (between 2014-2019 in Intermed hospital) were analyzed. Virological response was assessed at the end of treatment and during follow-up at 24 and more than 48 weeks post-therapy.

Results: At the end of treatment, biochemical and virological responses were observed in 19.4% (n=7) and 27.8% (n=10) of patients, respectively. At 24 weeks follow-up, 50% (n=18) and 22.2% (n=8) of patients showed biochemical and virological responses. Sustained virological responses were observed in 22.2% (n=8) at 48 weeks, with HDV RNA reappearance in 4 patients. HBsAg-positive patient exhibited seroconversion. Antiviral treatment for over 48 weeks resulted in responses in 11.1% (n=4), including two with HBsAg loss.

Conclusions: Our study reveals sustained HDV clearance in approximately one-ninth of CHD patients. Reduced HBsAg levels, not only during treatment but also in the follow-up period, emerged as a primary predictor for long-term treatment response. These findings underscore the importance of monitoring HBsAg levels for effective CHD management.
Background: Ectopic lipid accumulation in kidney leads to lipotoxicity and contributes to development of diabetic nephropathy (DN). Recently, Apolipoprotein J (ApoJ) is recognized as a hepatokine and participates in lipid and glucose homeostasis. Herein, we reported that accumulation of ApoJ in renal tubule promotes renal injury and facilitates DN progression.

Methods: The pathways involved in ApoJ-associated pathogenesis were identified by Omics analysis and validated using in vitro gain- or loss-of-function assays and in vivo tissue-specific ApoJ knockout mice. A co-immunoprecipitation assay was applied to verify the interactions between ApoJ, mammalian target of rapamycin (mTOR), and transcription factor EB (TFEB). The autophagy-lysosome pathway was dynamically addressed by live image analysis and autophagic flux assay. The efficacy of ApoJ antagonist peptide on DN was evaluated in mouse models of obesity and diabetes.

Results: Elevating in ApoJ levels were found in serum and renal tubules and exerted positive correlations with renal tubular injuries in mouse models of DN. Functionally, ApoJ facilitated mTOR-TFEB interaction, leading to disturb lipid homeostasis and promote epithelial-mesenchymal transition of proximal tubular cells. Coordinated with endogenous ApoJ, accumulation of hepatocyte-derived ApoJ in renal tubule was found to accelerate DN progression. Moreover, targeting ApoJ reactivated TFEB, restored autophagy, and prevented accumulation of lipid and reactive oxygen species. Finally, a peptide antagonizing ApoJ chaperone activity reversed lipid deposition and fibrosis in mouse models of DN.

Conclusion: ApoJ promotes renal injury by inducing lipid and ROS accumulation through mTOR-TFEB-autophagy axis and proposed ApoJ antagonist peptide as a novel therapeutic strategy against DN.

Abstract Submission No. 100890

All pediatric fatty liver diseases are not non-alcoholic fatty liver disease (NAFLD)

Alankrita Madhur1, Priti Vijay2, Dilip Ramrakhiani1

1Senior Resident, Department of Pathology, SMS Medical College & Attached Group of Hospitals Jaipur India, 2Assistant Professor, Department of Pediatric Medicine, Sir Padampat Institute of Neonatal and Pediatric Health, SMS Medical College Jaipur India, 3Senior Professor, Department of Pathology, SMS Medical College & Attached Group of Hospitals Jaipur India

Background and objectives: Fatty liver is the most common cause of chronic liver disease in adults due to obesity, whereas pediatric fatty liver disease has wide spectrum of etiology apart from obesity. In this study we aimed to identify all causes of fatty liver in children.

Methods: From June 2021 to June 2023 all liver biopsies done under follow up.

Results: Out of 25 liver biopsies, 15 were of infants. Median age at the time of biopsy was 7 years (Range 1 month-15 years) and 10 were females. Median weight and BMI (Median, IQR) were 38(20-48) & 26 (16-32) respectively. Median Platelet count, AST, ALT, Total Bilirubin was (Median, IQR) 202 (180-250), 165(100-236), 178(97-267), 6 (2-8) respectively. Etiologies of fatty liver were metabolic syndrome and obesity in 4, Wilson’s disease in 4, Glycogen storage disorders in 4, tyrosinemia in 2, celiac disease in 2, malnutrition in 2, Lysosomal acid lipase deficiency in 1, hereditary fructose intolerance in 1, Zellweger syndrome in 1, Cystic fibrosis in 1, steroid toxicity in child with nephrotic syndrome in 1, methotrexate toxicity in child with leukemia in 1, congenital generalized lipodystrophy in 1. All children were managed according to standard practice guidelines. Except Zellweger, congenital lipodystrophy and tyrosinemia all showed clinical improvement on follow up.

Conclusion: All pediatric fatty liver diseases are not due to metabolic syndrome & obesity. All efforts should be made to identify clear etiology to improve outcome.
Moinak Sen Sarma1, Nitu Kumari1, Srinivas Srinidhi Vadlapudi1, Anshu Srivastava1, Ujjal Poddar1, Surender Kumar Yachha1, Arghya Samanta1

1Dept of Pediatric Gastroenterology, Sanjay Gandhi Postgraduate Institute of Medical Sciences Lucknow India

Background: Galactosemia constitutes 2% of all neonatal cholestasis. Despite early diagnosis and dietary exclusion, there may be adverse liver and neuro-opthalmic outcomes. We analysed the risk factors of outcome in galactosemia patients.

Methods: Diagnosis was based on galactose-1-phosphatase uridyl transferase (GAL-1-PUT) enzyme <10 U/gHb or mutation of GALT gene. Risk factors of death or neuro-opthalmic morbidity (poor neuro-recognition, learning disability persistent cataract or ambylopia despite cataract surgery) were analysed from a prospectively maintained database.

Results: Fifty-one galactosemia patients presented as infantile cholestasis. Their median age of symptom onset and diagnosis were 10(1-90) and 45(7-450) days respectively. Figure 1 shows the natural history on lactose-free diet. Among the 43 survivors, 28 had follow-up with >6 months were analysed for long term outcome. All had normalisation in liver functions. Ten(36%) had adverse neuro-opthalmic outcome. Eighteen patients are currently asymptomatic in follow up till now. Multivariate analysis of non-survivors(n=8) versus survivors(n=28) identified risk factors: refractory ascites (88% vs.18%, p=0.012), persistent coagulopathy at 4 weeks (88% vs.25%; p=0.02), and culture-positive sepsis (63% vs 43%; p=0.04). In addition, pediatric end-stage liver disease (PELD) score <21 (sensitivity 78%; specificity 50%, p=0.02) and Child score <7.5 (sensitivity 89%; specificity 61%, p=0.01) predicted survival. PELD score correlated with culture-positive sepsis (p=0.05). In the 10 patients with poor neuro-opthalmic morbidity, no risk factors could be identified.

Conclusion: Refractory ascites, uncorrectable coagulopathy at 4 weeks of diagnosis and sepsis were associated with poor liver outcome. PELD and Child score predict survival. Long term neuro-opthalmic morbidity is not associated with disease severity at onset.

Serum iron overload activates SMAD pathway and hepcidin expression of hepatocytes via SMURF1

Pengyao Yang1, Ning Zhang1, Yanmeng Li1, Qin Ouyang1, Fei Hou1, Guixin Zhu1, Bei Zhang1, Jian Huang1, Jidong Jia1, Anjian Xu1

1Capital Medical University, Beijing Friendship Hospital Beijing China

Background: Liver iron overload can induce hepatic expression of bone morphogenic protein (BMP)6 and activate the BMP-SMAD pathway. However, serum iron overload also can activate SMAD while does not induce BMP6 expression. Therefore, the mechanisms whereby serum iron overload activates the BMP-SMAD pathway remain unclear. The aim of this study is to clarify the role of SMURF1 in serum iron overload and BMP-SMAD pathway.

Methods: Cell model of serum iron overload was established by hepatocytes treated with 2 mg/mL Holo-transferrin (Holo-Tf). Serum iron overload mice model and liver iron overload mice model were established by intraperitoneal injection of C57BL/6 mice with 10 mg Holo-Tf and by administration of high iron diet for 1 week followed by a low iron diet for 2 days, respectively. Western blot and Real-time PCR were performed to evaluate the activation of BMP-SMAD pathway and the expression of hepcidin.

Results: Holo-Tf could augment the sensitivity and responsiveness of hepatocytes to BMP6. E3 ubiquitin-protein ligase SMURF1 mediated the Holo-Tf-induced SMAD1/5 activation and hepcidin expression specifically. SMURF1 dramatically decreased when serum iron was overloaded. Additionally, the substrates of SMURF1, important molecules that transduce BMP-SMAD signaling, were significantly upregulated. Furthermore, in vivo analyses confirmed SMURF1 specifically regulates the BMP-SMAD pathway in serum iron overload.

Conclusions: SMURF1 can specifically regulates the BMP-SMAD pathway by augmenting the responsiveness of hepatocytes to BMPs in serum iron overload.

Hepcidin-inducer Laennec® can sorely improve congenital iron and copper metabolism disorder

YUKI HAMADA1, Eiichi HIRANO2, Keizo HANADA3, Taichi KAKU3

1HAMADA Clinic of Gastroenterology sapporo Japan, 2Japan Bio Products Co. Ltd. Kurume Research Center KURUME Japan, 3Japan Bio Products Co. Ltd. TOKYO Japan

Aims: Recent studies indicate that hepcidin deficiency underlies most known forms of hereditary hemochromatosis (H.H.). The high affinity of hepcidin for copper also suggests that hepcidin could bind copper in vivo. Thus Laennec® which can induce hepcidin may be effective not only for H.H. but for Wilson’s disease by regulating iron and copper metabolism through the action of hepcidin.

Case1 H.H.: 55-years-old male patient that developed type2 diabetes mellitus had elevated serum ferritin level (10,191ng/ml). Liver biopsies revealed remarkable iron deposition. Chromosomal analysis revealed the presence of TIR2 mutations. As the substitute for the repeated phlebotomy, the infusion with Laennec® (672mg/d,3times/w) has been done for 11 years. Recent serum ferritin levels were constantly below 550ng/ml. HbA1c also improved with the same dose of insulin (8.86.8%). Liver biopsy revealed the improvement of liver fibrosis (F3àF1).

Case2 Wilson’s disease: 45-years-old male patient with compensated liver cirrhosis presented neuropsychiatric signs. Liver biopsy revealed the presence of the deposition of copper and iron. The infusion with Laennec® has been done for these10 years. Liver biopsies revealed the remarkable improvement of both in fibrosis (F3àF1) and metal deposition.

Conclusion: The discovery of hepcidin and its role in heavy metal metabolism could lead to the development of novel therapies for H.H. and Wilson’s disease. The placenta-derived Laennec®, which can induce hepcidin solely improved iron overload of H.H. patient, and the impaired copper metabolism through chelating excessive copper in Wilson’s disease. The results suggest that Laennec® can take the place of venesecion for H.H. and other hepcidin-deficient diseases.

Evaluation of genetic markers contributing to disease predisposition in patients with MAFLD/NAFLD

Pramod Gautam1, Pooja Rao1, Nisha Choudhary1, Kuldeep Chaudhary1, Vipin Singh1, Rosmy Babu2, Chhagan Bihari2, Shiv Kumar Sarin3
Conclusion: The rising incidence of mortality and morbidity due to metabolic associated fatty liver disease (MAFLD) indicates towards genetic markers and their interplay with lifestyle factors to modulate the disease progression. Generally, 4 or 7 gene signatures are studied for the development and progression of MAFLD/NAFLD. The present study assesses the 68 MAFLD/NAFLD related genes in patients with different disease severity.

Methods: We sequenced 68 genes related to MAFLD/NAFLD phenotypes in 124 patients. The raw data after standard QC were mapped to GRCh38 and variants were called and annotated. The clinical impact of selected mutations was assessed by HGMD Professional and public databases for pathogenicity scores. Few of the genes included, APOB, APOE, FTO, PCSK9, PNPLA3, SAMM50 and TM6SF2.

Results: Out of 124 patients, 42 (34%) had clinical diagnosis of cirrhosis (NAFLD), 43 (35%) had NASH, 11 (8%) had MAFLD and 2 (2%) genetic cirrhosis with miscellaneous in 7 (6%) cases. Total of 168 variations were detected in the 118 patients which were relevant to the clinical phenotype with 6 cases reported no associated polymorphisms. The genes PNPLA3, PCSK9, GCKR and APOB together accounted for 88% of the observed genetic variations (n=148). Other genes included SAMM50, GPAM, TM6SF2 etc. (n=23, 12%). The major mutations included PNPLA3: Lys434Glu (n=43), PCSK9: Glu670Gly (n=25), GCKR: Pro446Leu (n=30) and APOB: Pro2739Leu (n=15).

Conclusion: Although PNPLA3 was most mutated gene, the mutations in GCKR, APOB and PCSK9 may also play a crucial role in MAFLD/NAFLD development and progression in Indian population.

Diagnostic genetic markers implicated in prothrombotic phenotypes in liver disease patients

Pramod Gautam1, Pooja Rao1, Nisha Choudhary1, Kuldeep Chaudhary1, Vinip Singh1, Rosmy Babu2, Chhagan Bihari2, Shiv Kumar Sarin2

1Senior Fellow, Genome Sequencing Lab, ILBS Delhi India, 2Dept of Pathology, ILBS Delhi India, 3Dept of Hepatology, ILBS Delhi India

Introduction: There could be risk of thrombosis in chronic liver disease both at inflow and outflow vessels. Previous reports from India have shown a very low frequency of inherited prothrombotic disorders in patients with vascular diseases. A thorough evaluation of predisposing prothrombotic genetic markers via sequencing is warranted in these patients.

Methods: We sequenced 44 genes related to thrombosis regulation in 88 patients (from Feb-Sep,23) with diagnosed vascular liver disorders. The genes included MTHFR, F5, F9, ADAMTS13 and VWF etc. Following standard QC measures, the clinical impact of selected mutations was assessed by HGMD Professional and public databases for pathogenicity/functional effects.

Results: Out of all, 70 cases had liver cirrhosis with partial/complete/chronic thrombosis of the portal vein, five patients had Chronic Budd-Chiari syndrome (BCH), and 12 patients had extra-hepatic portal vein obstruction (EHPVO). Upon analysis, 58% (n=51, Table) of the cases showed polymorphism associated with vascular thrombosis. In the thrombosis group, most mutations were in GCKR, GP6 and F13B (55%) e.g. GCKR: Pro446Leu, GP6: Ser219Pro and F13B: His115Arg. Similarly in the EHPVO group, F5 and FGA were most mutated (43%) e.g. FGA: Thr331Ala and F5: Arg534Gln. In BCH, CPB2: Thr347Ile, F13B: His115Arg, GP6: Ser219Pro and MTHFR: Ala222Val were observed.

Conclusion: The data presented here might prove useful in elucidation of molecular mechanism altering the regulation of coagulation factors, leading to risk of thrombosis.

Hepatomegaly from Poorly Controlled Type 1 Diabetes: A Rare Case of Mauriac Syndrome

Jan Bendric Borbe1, Jean Darlene Semilla2, Anatole Vallejos2, John Añonuevo2

1Division of Gastroenterology, Department of Medicine, University of the Philippines- Philippine General Hospital Manila Philippines, 2Department of Medicine, University of the Philippines- Philippine General Hospital Manila Philippines

Glycogenic hepatopathy is an underrecognized complication poorly controlled Type 1 Diabetes. Excessive glycogen accumulation in the hepatocytes may lead to massive liver enlargement. When hepatomegaly is accompanied by growth failure, a cushingoid appearance, and dyslipidemia, it is referred to as Mauriac syndrome. We describe a case of a 21-year-old female who was diagnosed with type 1 diabetes mellitus at the age of 8 and was maintained on insulin with poor compliance. She had recurrent hospitalizations for diabetic ketoacidosis since diagnosis. The patient also developed chronic kidney disease from diabetic nephropathy and has been on maintenance hemodialysis for 2 years. On examination, the patient was noticeably shorter compared to her parents with a height of 149cm and had visible abdominal enlargement with cushingoid facial features. The initial consideration for the abdominal enlargement was volume overload
from under dialyzed state. However, imaging revealed hepatomegaly (liver span 20cm) with no free fluid. She had regular follow-up at the outpatient clinic but had difficulty achieving adequate glycemic control from inconsistent insulin administration due to financial constraints. The patient eventually succumbed to complications of catheter-related bloodstream infection.

Strict glycemic control is the mainstay of treatment for hepatic glycogenosis. Complete reversal of hepatomegaly may be possible with improved control. Our case highlights the importance of recognizing the clinical features that comprise this rare syndrome to initiate timely management for this reversible condition.

The role of Vitamin E in the treatment of nonalcoholic steatohepatitis(NASH)

MOHAMED MAHBOOB ALI1

1ADVANCED MEDICAL AND DENTAL INSTITUTE(AMDI) GEORGETOWN Malaysia

Oxidative stress plays a vital role in the transition from simple steatosis to nonalcoholic steatohepatitis (NASH). An effective therapeutic strategy is to target the reduction of oxidative stress in these patients. Vitamins with antioxidant properties have the ability to act through multiple mechanisms to decrease the levels of reactive oxygen species in the body and prevent oxidative damage in the cell that can lead to cellular senescence and apoptosis. These properties may halt the progression of liver injury and facilitate the reversal of hepatic fibrosis in patients with NAFLD who are at risk for developing NASH. Thus, the aim of this study is to explore the functions of vitamin E in the treatment and recovery of patients suffering from NASH.

INTRODUCTION: Budd chiari syndrome (BCS) is considered as a disorder which mimics other disorders like constrictive pericarditis. We came across a case which was diagnosed and treated as BCS for 2 months, but it actually turn out to be a case of hepatic amyloidosis. CASE REPORT: We present a case of 35-year-old female with complaints of right upper quadrant pain for 1 year and insidious onset abdominal distension for 2 months. On examination patient was pale, had tachycardia, bilateral pedal edema and facial puffiness. Per abdominal examination revealed distended abdomen, shifting dullness and hepatomegaly. She was diagnosed as BCS based on her Triple phase CT abdomen findings and was being treated for same. However patient did not respond to the treatment. Patient was re-evaluated in our institute and her CT images were reviewed which showed thinned out hepatic veins, hepatomegaly and ascites however features like comma shape collaterals, regenerative nodules were not present. To confirm the diagnosis of BCS patient was taken up for hepatic venography which surprisingly revealed, no obstruction in hepatic veins. It was concluded that the false appearance of thinned out hepatic vein is likely due to extrinsic compression due to massive hepatomegaly. A liver biopsy was performed which confirmed the diagnosis of Amyloidosis.

CONCLUSION: This case is difficult and rare as triple phase CT abdomen was diagnostic of BCS but hepatic venography refuted the diagnosis and liver biopsy was performed which clinched the diagnosis of hepatic amyloidosis.

Wilson disease: Our observations over the past five years

Abu Saleh Md Sadequ Islam1, Mamun al Mahtab2, Salimur Rahman3

1SHAHEED ZIAUR RAHMAN MEDICAL COLLEGE BOGURA Bangladesh, 2BSMMU Dhaka Bangladesh, 3BSMMU Dhaka Bangladesh

Background: Wilson disease (WD) occurs worldwide with an average prevalence of ~ 30 affected individuals per million population. WD is due to mutations of the ATP7B gene on chromosome 13, which encodes a copper-transporting P-type ATPase (ATP7B) and responsible for decrease excretion of copper into bile and reduce synthesis of functional ceruloplasmin resulting accumulation of copper in affected tissues. Clinical presentation varies widely commonly liver, brain, eyes, and blood.

Objectives: To evaluate clinical and laboratory presentation over the past five years.

Methods: This is a hospital based observational study carried out in the Department of Hepatology, Shaheed Ziaur Rahman Medical College Hospital (SZMCH), Bogura over a period of five years, from January 2017 to December 2021. Twenty-four index patients of Wilson disease were enrolled in the study. We followed Leipzig Score for Wilson’s disease diagnosis. Total score 4 or more, diagnosis established as WD.

Results: Among 24, 46 % were female (n=11) and mean age was 16.4 year with range from 07 to 34. Liver presentation were Isolated spleenomegaly 8.3% (n=2), Persistently elevated serum aminotransferase activity (AST, ALT) 8.3% (n=2), Fatty liver 20.8% (n=5), Cirrhosis: compensated 8.3% (n=2) or decompensated 20.8 (n=5), Acute liver failure 29.2% (n=7). Hospital mortality of acute liver failure were 70.2 (n=5) without liver transplantation. Among them Neurological and Psychiatric manifestation were 16.6 % (n=04) and 45.8 % (n=11) respectively.

Conclusions: The spectrum of liver disease in WD are highly variable. If unexplained hepatic, neurologic or psychiatric Symptoms present we should carefully look for WD.

Lipid-Associated Macrophages Fuel NAFLD Fibrosis via CD36-Mediated Lipid Uptake & OPN Release

Zhe Dai1, Yinjin Wang1

1Southern University of Science and Technology, School of Medicine, Shenzhen China

Background and Aims: In the context of non-alcoholic fatty liver disease (NAFLD), a progressive transition occurs, replacing resident Kupffer cells (KCs) with distinct lipid-associated macrophages (LAMs) characterized by CD36 upregulation. However, the precise roles and mechanisms of CD36-expressing LAMs in NAFLD pathogenesis remain elusive.
Methods: We investigated LAM traits through single-cell RNA sequencing (scRNA-seq). Oleic acid (OA)-treated THLE-2 cells were co-cultured with THP1 macrophages to mimic LAMs and explore their in vitro functions. We also used high-fat diet (HFD) and methionine-choline-deficient (MCD) NASH mouse models.

Results: ScRNA-seq and in vitro data showed elevated CD36 expression in LAMs, linked to an immunosuppressive profile. By utilizing a co-culture system, we were able to confirm that the increased expression of CD36 in LAMs facilitated a more efficient uptake of lipids from hepatocytes with steatosis, subsequently triggering osteopontin (OPN) release via peroxisome proliferator-activated receptor gamma (PPARγ) pathway. ChIP-seq data and ChIP-qRNA experiments confirmed PPARγ regulation of SPP1, encoding OPN. OPN-stimulated hepatic stellate cells (HSCs) exhibited elevated alpha-smooth muscle actin (α-SMA) and collagen type 1 alpha 1 (COL1A1), driving liver fibrosis. CD36 silencing or inhibition in LAMs reduced lipid uptake and OPN release, mitigating fibrosis, observed in vitro and in mice. Combining a CD36 inhibitor with pioglitazone synergistically curbed fibrosis in murine models.

Conclusion: CD36 aids lipid transfer from hepatic cells to macrophages, activating hepatic stellate cells, and promoting liver fibrosis. Identifying CD36 as a potential therapeutic target holds promise for treating advanced NAFLD-associated fibrosis.

GLP-1RAs regulate lipid metabolism and induce autophagy through AMPK/SIRT1 pathway to improve NAFLD

Chun-Yan Niu1, Qiang Zhang2

1Department of Gastroenterology, Lishui District People’s Hospital, Zhongda Hospital Lishui Branch, Southeast University Nanjing, China, 2Yancheng Third People’s Hospital (The Yancheng School of Clinical Medicine of Nanjing Medical University) Yancheng, Jiangsu Province, China China

Background: Non-alcoholic fatty liver disease (NAFLD) is a leading cause of cirrhosis and a major risk factor for hepatocellular carcinoma and liver-related death. Diabetes medications have been studied as potential treatments for NAFLD. Glucagon-like peptide-1 agonists (GLP-1RAs) have been rarely reported in the treatment of NAFLD alone as an anti-diabetic drug, and its specific mechanism of action is unknown. We investigated whether the therapeutic effect of liraglutide (LRG, a representative drug of GLP-1RAs) on hepatic steatosis is related to regulating lipid metabolism and enhancing autophagy in the hepatocytes.

Methods: We examined the effect of LRG on fat accumulation in fatty hepatocytes, and discussed its effects on enzymes related to lipid metabolism and autophagy. Meanwhile, knockdown of SIRT1 in free fatty acids (FFA)-treated cells was used to detected the influence of LRG on lipid metabolism and autophagy by regulating of AMPK/SIRT1 signaling.

Results: Our findings showed that free fatty acids (FFA) induced hepatocyte steatosis, which was significantly reversed by LRG. Meanwhile, LRG significantly regulated the expression of hepatocyte lipogenesis and cytosolic lipolysis-related proteins (FAS, ACC1, ATGL, HSL, LAL). Furthermore, LRG enhanced FFA-induced suppression of autophagy and SIRT1 expression, reducing intracellular lipid accumulation. It is evident that LRG regulates lipid metabolism and induces autophagy in an (AMPK)-dependent manner. Moreover, SIRT1 knockdown inhibited the autophagy-inducing and lipid-lowering effects of LRG.

Conclusion: GLP-1RAs may improve hepatic steatosis by regulating lipid metabolism and enhancing autophagy in an AMPK/SIRT1-dependent manner, which providing a new target for the treatment of NAFLD.

Amitriptyline inhibits NLRP3 inflammasomes activation via suppressing the ASM/CE pathway in NAFLD

Chun-Yan Niu1, Qin Liu2

1Department of Gastroenterology, Lishui District People’s Hospital, Zhongda Hospital Lishui Branch, Southeast University Nanjing, China, 2Shengli Clinical Medical College of Fujian Medical University Fuzhou China

Background: Both Acid sphingomyelinase (ASM)/ceramide (CE) and NLRP3 inflammasome pathway are involved in the occurrence and development of NAFLD. However, it has not been reported whether ASM / CE pathway promote the occurrence of NAFLD by acting on the NLRP3 inflammasome pathway in vitro. Therefore, we conducted relevant cytopathological research.

Methods: NAFLD model cells were divided into 5 groups. The changes of intracellular lipid droplets and cell viability was detected, the biochemical metabolism indexes were determined. Western blot was used to measure ASM, NLRP3, caspase-1 protein expression; ELISA was used to detect the level of CE and ASM; the mRNA expression of ASM and IL-1β was tested by RT-PCR; the apoptotic rate of cells was evaluated by flow cytometry (FCM).

Results: ASM and CE levels in the NAFLD model group were significantly increased, along with the increase of the expressions of NLRP3, Caspase-1, IL-1β, and TG, TC, ALT, AST and MDA. These indicators further increased in the TNF-α group. Amitriptyline suppressed ASM and CE, decreased the levels of all the above biochemical and inflammatory biomarker, and reduced lipid droplets accumulation and improved apoptosis. MCC950 down-regulated the expressions of NLRP3, caspase-1 and IL-1β, improved lipid deposition and apoptosis in the cell of NAFLD.

Conclusions: ASM/CE-NLRP3 inflammasome pathway is a pivotal mechanism of hepatocyte steatosis, inflammation, and cell damage in NAFLD. Amitriptyline can inhibit this pathway from the source and exert the anti-lipid deposition and anti-inflammatory effects, suggesting that ASM/CE-NLRP3 pathway is a key target in the treatment of NAFLD.

Elucidating the role of complement C3 in metabolic-associated fatty liver disease

Van Dien Nguyen1, 2, Timothy R. Hughes1, 2, Biron Zhang1, 2, B. Paul Morgan1, 2, You Zhou

1Division of Infection and Immunity, School of Medicine, Cardiff University Cardiff United Kingdom, 2Systems Immunity Research Institute, School of Medicine, Cardiff University Cardiff United Kingdom

Background: Metabolic-associated fatty liver disease (MAFLD) affects 30% of adults and is the leading cause of liver transplantation. Despite the growing threat, no approved treatment exists. Accumulating evidence suggests an important role of the complement system in causation of MAFLD. As the axial component of the complement
system, C3 is predominantly produced in the liver, the metabolic ‘engine’ of the body; however, its metabolic role remains little known.

**Methods:** This study comprehensively characterized C3 expression in normal and MAFLD livers using single nuclei RNA sequencing and bulk RNA sequencing. Data were validated in free fatty acid-induced steatotic human hepatocytes, and a mouse model.

**Results:** C3 exhibited zonal expression, abundant in perportal hepatocytes. Celluar deconvolution showed that MAFLD disrupted hepatic zonal structure, depleting pericentral hepatocytes while expanding cytoplasms. Cellular deconvolution showed that MAFLD disrupted hepatic interactions between liver donors and recipients on PTDM outcomes. We demonstrate the impact of lipid accumulation on C3 expression in hepatocytes and show that C3 knockout impacts hepatic lipid handling. Overall, our study provides new insights into the role of C3 in MAFLD pathogenesis and suggests its potential as a therapeutic target for the treatment of MAFLD.

**Conclusion:** We demonstrate the impact of lipid accumulation on C3 expression in hepatocytes and show that C3 knockout impacts hepatic lipid handling. Overall, our study provides new insights into the role of C3 in MAFLD pathogenesis and suggests its potential as a therapeutic target for the treatment of MAFLD.

**Donor and recipient genetic interactions: improving post-transplant diabetes outcomes**

**abraham shaded, oren akedsh, bao-li chang, kim olthoff, rajender reddy**

1university of Pennsylvania philadelphia United States, 2university of pennsylvania philadelphia united states, 3university of pennsylvania philadelphia united states, 4university of pennsylvania philadelphia United States, 5university of Pennsylvania philadelphia United States, 6university of Pennsylvania philadelphia united states

Post-transplant diabetes mellitus (PTDM) is a prevalent complication after liver transplantation and is linked to the emergence of cardiometabolic complications. We studied the consequences of the genetic interactions between liver donors and recipients on PTDM outcomes. Liver transplant recipients without pre-transplant diagnosis of type 2 diabetes mellitus (T2D) and their paired donors underwent genome-wide genotyping. Polygenic risk scores (PRS) for T2D, insulin secretion, and insulin sensitivity were calculated using observations available from independent large-scale genome-wide association studies.

**Results:** 1115 recipient-donor pairs were included. For recipients who had the lowest T2D genetic risk, donor livers with the highest T2D-PRS contributed to the development of PTDM (OR (95% CI) = 3.79 (1.10 - 13.1), p=0.035). Recipient risk was linked to factors associated with insulin secretion and β-cell function (OR (95% CI) = 0.85 (0.74-0.98), p=0.02), while the donor liver contributed to PTDM via gene pathways involved in insulin sensitivity (OR (95% CI) = 0.86 (0.75-0.99), p=0.03).

**Conclusion:** Recipient and donor PRS independently and collectively serve as predictors for the onset of PTDM. The genetically influenced biological pathways in recipients primarily pertain to insulin secretion, while the genetic makeup of donors exerts an influence on insulin sensitivity. Knowledge of recipient and donor T2D-PRS could potentially enhance metabolic genetic matching, particularly in the context of living donor liver transplantation.

**New AI-digital pathology indices predict adverse clinical outcomes in patients with MASLD**

**Kutbuddin Akbary, Timothy Kendall, Dean Tai, Gideon Ho, Ren Yuan, Elaine Chng, Jonathan Fallowfield**

1Histolindex Pte Ltd Singapore Singapore, 2Centre for Inflammation Research, Institute for Regeneration and Repair, University of Edinburgh Edinburgh UK
Background: Single-Harmonic-Generation/Two-Photon-Excitation (SHG/TPE) imaging reduces observer-related variability in histological assessment of Metabolic-dysfunction Associated Steatotic Liver Disease (MASLD). Other digital pathology methods provide ordinal scores, and clinical outcomes are strongly correlated with fibrosis stage. We applied SHG/TPE imaging to cases in the SteatoSITE multimodal MASLD dataset (www.nature.com/articles/s41591-023-02602-2) to generate new indices predicting clinical outcomes, without fibrosis stage as a surrogate, using collagen morphological features unapparent to human observers.

Methods: n=452 biopsies (training n=300, validation n=152) were imaged by SHG/TPE. Following sequential feature selection, 10, 10, and 5 of 184 fibrosis parameters were chosen and linear regression used to aged by SHG/TPE. Following sequential feature selection, 10, 10, and 5 of 184 fibrosis parameters were chosen and linear regression used to predict the risk indices were compared with NASH-CRN fibrosis stage (F0/1/2 vs. F3/4) and SHG/TPE imaging-derived qFibrosis stage (qF0/1/2 vs. qF3/4).

Results: Figure 1 shows that the newly-defined “All-cause Mortality Index” had greater predictive power for all-cause mortality risk (HR=4.49) than NASH-CRN (HR=3.65) or qFibrosis stage (HR=3.59), and the “ Decompensation Index” had greater predictive power for de-compensation events (HR=5.96) than NASH-CRN (HR=3.65) or qFibrosis stage (HR=3.59).

Conclusion: We used a training and internal validation set of clinically-annotated MASLD biopsies to develop novel SHG/TPE imaging-based tissue-to-outcome risk indices that accurately predicted all-cause mortality and hepatic decompensation events. If externally validated, these indices could be leveraged to enhance patient stratification in clinical care pathways or MASLD drug trials.

Liver fibrosis is associated with burden of cardiovascular disease in non-alcoholic steatohepatitis

Kathleen E. Corey1, Anurag Mehta2, Kamal Kant Mangla3, Abhishek Shankar Chandramouli4, Margarida Augusto5, Ahsan Shoaib Patel6, Sharat Varma7, Niels Moeetzuma Krarup8, Katrine Grau9, Elisabetta Bugianesi9

1MGH Fatty Liver Program Massachusetts General Hospital Boston, MA USA, 2VCU Health Pauley Heart Center Richmond, VA USA, 3Novo Nordisk A/S Søborg Denmark, 4Novo Nordisk Service Center India Pvt Ltd Bangalore India, 5Department of Medical Sciences, University of Turin Turin Italy

Background: This study assessed the burden of cardiovascular (CV) disease (CVD) in patients with non-alcoholic steatohepatitis (NASH), using real-world US healthcare data (TriNetX).

Methods: Patients were identified using the International Classification of Diseases code (ICD-10-CM) for NASH (index date) and required the following: ≥1 fibrosis-4 index (FIB-4) measurement(s); ≥12 months of data prior to index date; and no history of CV events or cirrhosis at baseline. CV events were analyzed with FIB-4 continuous baseline FIB-4 measurements, a significantly increased risk of any and individual CV events was observed as FIB-4 increased (Figure). The risk of any CV event increased by 1.3% (HR 1.013; 95% confidence interval [CI] 1.006, 1.02; p=0.0003) and 14% (HR 1.14; 95% CI 1.06, 1.22; p=0.0003) for each 0.1- and 1-unit increase in FIB-4, respectively. For high and intermediate vs low FIB-4, adjusted HRs (95% CI) for any CV event were 2.05 (1.23, 3.41); p=0.006 and 0.87 (0.55, 1.37); p=0.5405.

Conclusions: Fibrosis assessed by baseline FIB-4 scores is associated with increasing clinical burden due to CVD, in terms of risk for CV events.

Ferroptosis is a cell death at an early stage of MASLD in a mouse model

Kouichi Miura1, Oyunjargar Bat-erdene1, Hiroshi Maeda2, Naoki Morimoto3, Hironori Yamamoto4

1Jichi Medical University Shimotsuke Japan

Background: Ferroptosis is a new form of cell death, characterized by the iron-dependent accumulation of lipid hydroperoxides to lethal levels. However, little information is available on the association between ferroptosis and MASLD.

Methods: Male hepatocyte-specific PTEN KO (PTEN KO) mice were used as a MASLD model. Huh7 was used in vitro experiment. Ferrostatin-1, a ferroptosis inhibitor, and apomorphine, a drug for Parkinson’s disease that has anti-ferroptotic function were used.

Results: PTEN KO mice at 10-week-old showed a moderate grade of steatosis but few hepatocyte ballooning, a hallmark for necrosis. In addition, PTEN KO mice showed increased oxidative stress markers, elevated serum transaminases, and increased proinflammatory and profibrogenic genes in the liver. There were few apoptotic cells and a certain number of hepatocytes positive for lipid peroxide accumulations (PI), a marker for necrosis. Treatment of ferrostatin-1 and apomorphine for 2 weeks ameliorated the features of MAFLD. There were no significant changes in hepatic iron contents in mice treated with ferrostatin-1 or apomorphine. Although necrosis inhibitor did not decrease the number of PI-positive hepatocytes, both ferrostatin-1 and apomorphine decreased the number of PI-positive hepatocytes. In vitro experiments, ferroptosis inducer RSL-3 induced cell death. This cell death was inhibited by ferrostatin-1 and apomorphine but not by necrosis inhibitor. In addition, cell death induced by RSL-3 were positive for PI, which were suppressed by ferrostatin-1 and apomorphine but not a necrosis inhibitor.

Conclusions: Ferroptosis contributes to cell death in an early stage of MASLD. Inhibition of ferroptosis is a potential treatment for MASLD.

NPC1 deficiency mediates autophagy impairment in NAFLD and serves as a target for NAFLD treatment

Qin NING1, Qiang Gao1, Suping Hai1, Xinliang Li2, Wenhui Wu1, Erliang Xie1, Binghui Yu1, Junjian Hu1, Xiaojing Wang1

1Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology Wuhan China

Background: One important pathogenesis of NAFLD attribute to the imbalance of lipid metabolism, autophagy serves as a critical lipid metabolism pathway, but it impaired in NAFLD. We found Niemann-Pick...
C1 (NPC1), a transmembrane protein related to autophagy function, decreased dramatically in NAFLD, we aimed to investigate the role of NPC1 in NAFLD pathogenesis.

Methods: NAFLD mice model was established by feeding with high fat diet (HFD), pharmacological interventions were administrated by intraperitoneal injection. Palmitic acid (PA) was used to stimulate cells to establish NAFLD cell model, agents to regulate autophagy were added in the beginning of PA treatment. Lipid metabolism and autophagy function were tested.

Results: Autophagy flux was impaired in downstream in NAFLD which indicated by the increase of LC3II and P62. A dramatic decrease of NPC1 was detected, by using HP-b-CD, DOPG or Thioperaamide to compensate NPC1 function, we observed increased autophagy flux in vitro. Furthermore, Thioperaamide increased the level of NPC1 in vivo. but only when coupled with upstream activator RAPA, the lipid deposition could be eliminated. So, we sought for a strategy to stimulate autophagy both in upstream and downstream, and found the TFEB activator could improve autophagy flux and eliminate lipid deposition in NAFLD by stimulate autophagosome formation and NPC1 expression.

Conclusions: NPC1 deficiency serves as a critical role in downstream autophagy impairment in NAFLD. Stimulating both upstream and downstream autophagy is a feasible strategy to reverse the progression of NAFLD in vivo. TFEB activator seems to be an ideal approach to reverse NAFLD.

**O-0280**

Mesenchymal stem cells restore NASH by ameliorating ER stress in the local environment of the liver.

Akihiro Seki1, Norihiko Ogawa1, Alessandro Nasti2, Yoshio Sakai2,1, Taro Yamashita2, Tuyen Ho Thuy Bich2

1Gastroenterology, Kanazawa University Hospital Kanazawa Japan, 2Information-Based Medicine Development Kanazawa Japan

Background: Mesenchymal stromal cells (MSCs) are expected to be the next novel therapy for liver diseases. Endoplasmic reticulum (ER) stress progresses NASH by cellular dysfunction and apoptosis of hepatocytes. In this study, we investigated the modulatory effect of MSCs on ER stress in a NASH mouse model.

Methods: MSCs, isolated from inguinal adipose tissue of C57Bl/6J mice, were injected into the splenic sub-capuscle of NASH mice established by high-fat atherogenic (HF-AT) diet feeding. Liver tissues were collected for gene and protein expression analysis and immunohistochemistry. In vitro, murine immortalized hepatocytes (H2.35) were cultured with conditioned media of IMS/N alone or IMS/N-MSC co-culture. Cell viability of H2.35 was assessed, and RNA or proteins were isolated from H2.35 or IMS/N.

Results: In response to HF-AT diet feeding, expression of Perk-related genes were upregulated in the NASH liver, and MSC treatment ameliorated the Perk-related genes compared to control. In addition, MSC treatment decreased the apoptotic cells and alpha SMA-positive activated stellate cells in the liver of NASH mice. In vitro, IMS/N-culture media induced expression of the Perk molecule. The IMS/N-culture media enhanced the Perk expression of H2.35, meanwhile, the media of IMS/N co-cultured with MSCs did not. Alpha SMA staining showed the de-activation of IMS/N co-cultured with MSCs. DNA microarray analysis revealed that IMS/N co-culture with MSCs attenuated the expression of 1182 genes related to CCL2, IL17, IL1, and HMGBl/RAGE signaling.

Conclusion: Adipose tissue-derived MSCs novel treatment ameliorated the NASH condition by alleviating the ER stress induced by hepatic stellate cells in hepatocytes.

Edaravone promotes the AMP-activated protein kinase to relieve nonalcoholic steatohepatitis in mice

Xiaoning Chen1, 2, Yanying You1, 2, Hanxin Xue1, 2, Lisha Wu1, 2, Danyi Zeng0, Qingqing Xing1, 2, Minxia Wu1, Jiaofeng Huang1, 2, Su Lin0, Jinshui Pan0, Yueyong Zhu0

1The First Affiliated Hospital, Fujian Medical University Fuzhou China, 2Fujian Clinical Research Center for Liver and Intestinal Diseases Fuzhou China

Objective: The global burden of nonalcoholic steatohepatitis (NASH) is increasing. Edaravone (EDA) has various biological and pharmacological activities, including anti-inflammatory and anti-oxidant activities. However, the effects of EDA on NASH remain unclear.
Methods: Steatosis cells were induced by palmitate/oleic acid (PO) in vitro. To establish the NASH animal model, C57BL/6j mice were fed a high-fat/high-cholesterol (HFHC) diet for 24 weeks. Furthermore, EDA were administered by intragastric gavage every day for 16 weeks. Glucose and insulin tolerance tests were used to investigate insulin sensitivity. Serum enzymes and lipids were assayed by a biochemistry analyzer. Histological analysis of the liver included HE, Oil red, and Sirius red staining. RNA-sequencing, real-time qPCR, and western blotting were used to investigate the expression of genes associated with lipid metabolism, inflammation, and fibrosis

Results: EDA alleviated lipid accumulation and inflammation in both HepG2 and AML12 cells after PO stimulation. In addition, EDA prevented HFHC-induced insulin resistance, lipid accumulation, liver inflammation, and liver fibrosis in NASH mice. Mechanistically, RNA-sequencing and western blotting suggested that EDA could promote AMPK-signaling pathway activation in vitro and in vivo, and this finding was further verified by determining the phosphorylation levels of AMPKα at the site of T172. Furthermore, the protective effects of EDA on lipid accumulation and inflammation in hepatocytes and livers induced by PO or HFHC disappeared under the effects of the AMPK inhibitor.

Conclusions: EDA protects against metabolic-stress-induced NASH progression through activation of AMPK signaling, indicating that EDA had the potential to be a promising drug for NASH therapy.

Abstract Submission No. 102054

iNKT cells are key players in the progression of murine steatohepatitis caused by Western diet

Kazuyoshi Kon1, Akira Uchiyama1, Hiroo Fukada1, Shunhei Yamashina1, Kenichi Ikemijama2

1Juntendo University School of Medicine Tokyo Japan

Aim: We investigated the role of type 1 (iNKT cells) and type II NKT cells in age-related exacerbation of metabolic dysfunction-associated steatotic liver disease (MASLD).

Method: C57BL/6 mice, iNKT cells KO mice (Vα14KO), and all NKT cells KO mice (CD1dKO) aged 8 w.o (young) and 55 w.o (elder) mice were fed a high-fat/high-cholesterol diet (HFHC) or a control diet for 8 weeks.

Results: Whereas HFHC-fed wild young mice developed trivial hepatic steatosis with slight elevation of serum ALT levels to 54±11 IU/L, HFHC-fed wild elder mice showed severe macrovesicular steatohepatitis with marked elevation of serum ALT levels to 406±46 IU/L. Serum ALT levels significantly decreased to 268 ± 45 IU/L in Vα14KO elder mice, and further decreased to 159 ± 23 IU/L in CD1dKO elder mice. HFHC increased hepatic TNFα and TLR4 mRNA twice as much in elder mice as in young mice. HFHC-induced upregulation of TNFα and TLR4 in elder mice was equally significantly suppressed in both Vα14KO/CD1dKO mice. Sirius-Red staining showed pericentral fibrosis in elder mice fed an HFHC, while fibrosis was not observed in HFHC-fed Vα14KO/CD1dKO. Expression of TGFβ mRNA was enhanced only in HFHC-fed elder mice and was equally significantly suppressed in both HFHC-fed Vα14KO/CD1dKO mice.

Conclusion: These findings indicated that iNKT cells are more deeply involved in the induction of inflammatory cytokines and fibrogenesis although both iNKT cells and type II NKT cells are prominently involved in steatohepatitis in aged mice. It was concluded that iNKT cells play an important role in age-related exacerbation of MASLD.

Spatio-temporal immune landscape of tertiary lymphoid structures in non-alcoholic steatohepatitis

Jie Ma1,2,3, Shiming Gong1,2,3, Qiang Xia1,2,3, ZhenZhen Zhan1,2,3

1Department of Liver Surgery, Renji Hospital, School of Medicine, Shanghai Jiao Tong University Shanghai China, 2Shanghai Institute of Transplantation Shanghai China, 3Shanghai Engineering Research Center of Transplantation and Immunology Shanghai China

Background: The global epidemic of non-alcoholic fatty liver disease (NAFLD) and its more severe form, non-alcoholic steatohepatitis (NASH), represents a significant health and economic burden with no approved pharmacotherapy. Therapeutic promotion of sustained suppression of inflammation holds great promise for NASH, while the adaptive immunological mechanisms controlling hepatocyte injury in NASH remain largely unknown.

Methods: In this study, we horizontally investigated the immune landscape of NASH in both clinical samples and preclinical models by comprehensive multi-omic profiling, including spatial transcriptomics (ST), single-cell RNA sequencing (scRNA-seq), bulk RNA
sequencing, tandem mass tagging (TMT)-based proteomics, multiplex immunohistochemical (miHC) staining and H&E staining. C57BL/6J wild-type (WT), B-cell-deficient and transgenic mice were fed different NASH-inducing diets, after which NASH and fibrosis were assessed and analysed.

**Results:** We profiled the spatially resolved transcriptomic architecture of the NASH microenvironment and identified the presence of tertiary lymphoid structures (TLSs) with characteristic spatial patterns and involving genes associated with immune metabolism, cytokine and chemokine signalling, and extracellular matrix remodelling. These TLSs formed a functional hub and contributed to an active in situ process of B cell maturation towards plasma cell (PC) formation, autoantibody accumulation and the initiation of IgG-dependent hepatocyte apoptosis. Meanwhile, robust preclinical evidences demonstrated that B-cell depletion, BTK deficiency and acalabrutinib were effective in blocking B-cell activation, reducing IgG levels and ameliorating NASH phenotypes.

**Conclusions:** Our comprehensive immune profiling confirms the dark side of B-cell-rich TLS in both clinical NASH patients and highly translatable preclinical NASH models, highlighting the need for clinical evaluation of BTK inhibitors in NASH.

**Mechanistic study of tyrosine kinase inhibitors against metabolic-associated fatty liver disease**

**Han Kiat Ho1, Bhave Sayali Shrivardhan1**

1National University of Singapore Singapore Singapore

The pre-eminence of metabolic-associated fatty liver disease (MAFLD) in the general population calls for more targeted efforts to address this growing problem. While some tyrosine kinases (e.g. EGFR and MET) have been linked to the regulation of lipid homeostasis within the liver, their strategic advantage as pharmacological target has not been evaluated comparatively across the different sub-types of receptor tyrosine kinases. Hence, our lab addressed this research question head-on by using classical inhibitors for different receptor tyrosine kinases and apply them on both drug-induced and diet-induced models of lipid accumulation in liver cell lines. We evaluated their pharmacological potential by measuring the reduction in lipid accumulation as our phenotype-based assay. Thereafter, we explored the mechanism of action by investigating specific biochemical processes relevant to the disposition of lipids: fatty acid uptake, de novo lipogenesis, fatty acid oxidation, VLDL secretion and lipophagy. From this effort, two distinct tyrosine kinases were found to be pivotal in the regulation of lipid accumulation, namely EGFR and AXL. They play significant roles in modulating de novo lipogenesis and fatty acid oxidation, but they differ in the utilization of cell signaling pathways to achieve this. Critically, they present opposing effects on lipophagy which raises questions on the criticality of this process in the overall regulation of lipid homeostasis. Subsequent study using mice on MCD diet ascertained the manifestation of overall lipid reduction in the liver, as well as an attenuation of liver injury. These findings support further work to evaluate the feasibility of this therapeutic strategy.

**Abstract Submission No. 100078**

**O-0287**

**CD18 deficiency ameliorates NASH by inhibiting lipid synthesis and downregulating Th1 cells in mice**

Bayasi Guleng1, Xian-Ling Zhao1

1Department of Gastroenterology, Zhongshan Hospital of Xiamen University; School of Medicine, Xiamen University Xiamen China

**Background & Aims:** Nonalcoholic steatohepatitis (NASH) is the progressive stage of nonalcoholic fatty liver disease, which has a higher chance of progressing to end-stage liver disease, and there is an urgent need to find new molecular mechanisms and therapeutic targets. Contemporary studies have indicated the potential involvement of CD18 in governing cellular metabolic pathways. We aimed to explore the function and mechanisms of CD18 in NASH.

**Methods:** The investigation of the expression levels of CD18 in the liver tissue of NASH patients applied the GEO database. Then WT mice and CD18−/− mice were given a normal chow diet or a western diet (WD) for 16w to produce NASH model. A series of experimental methods were used to assess the expression of CD18 in NASH mice and its effect on NASH-related phenotypes. Flow cytometry and RT-qPCR were used to explore the possible regulatory mechanisms of CD18.

**Results:** Both NASH patients and mice showed remarkably elevated levels of CD18. In WT mice, the western diet causes obesity, steatosis, insulin resistance, fibrosis, and inflammation. CD18 deficiency significantly reduces these effects. Compared with WT WD mice, CD18−/− WD mice had decreased expression of lipid synthesis genes, increased expression of lipid oxidative catabolic genes, and lower numbers of Th1 cells in liver tissue.

**Conclusions:** The expression of CD18 was significantly increased in NASH patients and mouse models. Through the inhibition of lipid synthesis and a decrease in Th1 cell infiltration in liver tissue, CD18 deficiency reduces obesity, steatosis, insulin resistance, and inflammation in NASH mice.

**MicroRNA 29a ameliorates NAFLD by attenuating the MAVS pathway and mitigating liver steatofibrosis.**

Ying-Hsien Huang1, Ya-Ling Yang1

1Kaohsiung Chang Gung Memorial Hospital Kaohsiung Taiwan

**Aim:** Non-alcoholic fatty liver disease (NAFLD), the most common cause of chronic liver disease, consists of fat deposited (steatosis) in the liver due to causes other than excessive alcohol use. NAFLD is a also hepatic manifestation of the metabolic syndrome.

**Methods and Materials:** We utilized miR-29a transgenic mice (miR-29a) and wild-type (WT) mice, subjecting them to a 36-week high-fat Western diet (WD) regimen to induce the NAFLD model. Hepatocellular steatosis was assessed through histopathological analysis, and dsRNA was detected via immunofluorescence staining, and other biochemistry assays.

**Key Findings:** The findings indicated that overexpression of miR-29a significantly curtails weight gain, lowers elevated AST/ALT levels, and reduces steatofibrosis in WD diet-treated mice. Moreover, miR-29a overexpression inhibits GSK3β expression, enhancing HSP60 levels and decreasing dsRNA in WD mice. Additionally, miR-29a over-expression diminishes the mitochondrial antiviral-signaling (MAVS) pathway in WD mice. This suppression of MAVS expression occurs through direct binding to its 3' UTR. In the HepG2 cell line, miR-29a mimics directly inhibits MAVS expression.

In conclusion: Our results support that miR-29a improves NAFLD by dampening the mitochondrial antiviral-signaling (MAVS) pathway and alleviating liver steatofibrosis.

**GSK-3β inhibition for stimulation of liver regeneration in partially hepatectomized rats**

**Vaibhav Sapra**, Onkar Bedi

1Chitkara College of Pharmacy, Chitkara University, Punjab, India, 2Chitkara College of Pharmacy, Chitkara University, Punjab, India

**Background:** The primary treatment for Chronic Liver Disease (CLD) involves dietary and non-dietary interventions. However, when CLD progresses to end-stage liver disease, liver transplantation becomes the only viable option, despite challenges such as donor shortages, transplant rejection, immunosuppressive drug complications, and high costs. To address the urgent need for post-transplantation liver regeneration, the growing focus is emphasized on stimulation of liver regeneration by pharmacological intervention, even in non-transplanted individuals or those with early liver complications.

**Method:** Present study aimed to stimulate the Wnt/β-catenin signaling pathway by inhibiting GSK-3β to promote hepatocyte replenishment and liver regeneration. A partial hepatectomy was performed on 44 rats, with the animals divided into six groups and assessed from postoperative days one to eight. The effects of the GSK-3β inhibitor CHIR99021 (6.25mg/kg/b.w.) on hepatic regeneration and hepatoprotection were evaluated using biochemical, histopathological methods, and docking studies.

**Results:** It was indicated that both single and repeated doses of CHIR99021 significantly improved lipid profiles, liver function, and reduced oxidative stress in partial hepatectomized rats on the 3rd and 7th day as compared to those without drug treatment. Histopathological assessments confirmed substantial hepatocyte regeneration after CHIR99021 treatment, supported by docking studies that showed significant binding interactions with essential amino acids of the protein. Mitotic cell phase determination also validated the histopathological findings in different rodent groups (Fig 1).

**Conclusion:** In conclusion, pharmacological stimulation of the Wnt/β-catenin pathway through GSK-3β inhibition with CHIR99021 demonstrated promising results in promoting hepatocyte regeneration, potentially offering a new treatment strategy for liver regeneration.

**Transcriptome analysis revealed FABP5 as a serum marker of metabolic associated fatty liver disease**

**Zhiyu Yang**, Junru Zhou, Binfyong Zhang, Xiuling Li

1Department of gastroenterology, Henan Provincial People’s Hospital, People’s Hospital of Zhengzhou University, Zhengzhou, Henan Province, China, 2Zhengzhou University, Zhengzhou University, People’s Hospital of Zhengzhou University, Zhengzhou, Henan, China

**Abstract:**

**Objective:** The pathogenesis of metabolic (dysfunction) associated fatty liver disease (MAFLD) is very complex, which has not been fully revealed as so far. In our study, the third-generation ONT (Oxford nanopore technologies) sequencing platform was used to explore the key differentially expressed genes involved in the pathogenesis of MAFLD.

**Methods:** In the present study, we firstly fed male C57/BL6N mice with high fat and high fructose (HFHF) diet for 19 weeks to induce MAFLD model while setting up a normal diet control group (Chow).

Secondly, we collected the liver tissues of the two groups and used the ONT technology to perform transcriptome analysis. Finally, we verified the sequencing results by quantitative polymerase chain reaction (qPCR) and measured the serum concentrations of fatty acid-binding protein 5 (FABP5) in mice and patients with MAFLD by Enzyme linked immunosorbent assay (ELISA).

**Results:** By transcriptome analysis, we found that there were 400 differentially expressed genes between the two groups, 12 of which participated in lipid transport and metabolism. Furthermore, we discovered that the serum level of FABP5 decreased significantly in patients with MAFLD, compared with healthy controls.

**Conclusion:** Involved in lipid transport and metabolism, FABP5 could be used as a serum marker of MAFLD.

**Pharmacological exploration of FAS inhibitors for managing diabetic & non diabetic-liver injury**

**Onkar Bedi**, Niharika Srivastava, Davinder Parsad, Pawan Krishna

1Chitkara College of Pharmacy, Chitkara University, Punjab Rajpura India, 2Department of Dermatology, Venereology and leprosy, PGIMER Chandigarh India, 3Department of Dermatology, Venereology and leprosy, PGIMER Chandigarh India, 4Department of Pharmaceutical Sciences and Drug Research, Punjabi University, Patiala, Punjab India

**Objective:** The onset and development of liver damage is considered to be influenced by drugs and bad dietary habits.

**Methods:** The current study also aims to investigate the relation between paracetamol and high fructose + high fat produced diabetic and non-diabetic liver damage in context of innovative pharmacological therapies (Pterostilbene, Arbutin and Purpurin) with respect to their anti-adiopogenic and hepatoprotective effect (Figure 1). The various biochemical, oxidative stress and qRT-PCR parameters were considered for the evaluation of selected interventions.

**Results:** High fat and fructose diet intake for 28 weeks markedly (P<0.05) upsurge the level of glucose as compared to control diet treated experimental rodents. The scenario was reversed in the case of paracetamol treated rodents there was no significant (P<0.05) increase in the level of glucose which depicted the difference of diabetic and non-diabetic liver injury models. The lipid, liver, inflammatory (IL-6) level, oxidative stress and serum free fatty acid parameters were shown to possess significant (P<0.05) improvement in PTS, ARB and PUR treated groups as compared to the disease treated rodent groups.

**Conclusion:** It is hypothesized that reducing free fatty acid levels by Fatty Acid Synthase inhibition will improve insulin resistance and attenuate diabetic and non-diabetic Liver Injury.

Abstract Submission No. 100402

**O-0292**

**Oxidative-cellular bioenergetics governs the telomerase inhibition-induced senescence in hepatocytes**

**Pavitra Kumar**, Mohsin Hassan, Frank Tacke, Cornelius Engelmann

1Charité - Universitätsmedizin Berlin Berlin Germany, 2Charité - Universitätsmedizin Berlin Berlin Germany

**Objective:** The pathogenesis of metabolic (dysfunction) associated fatty liver disease (MAFLD) is very complex, which has not been fully revealed as so far. In our study, the third-generation ONT (Oxford nanopore technologies) sequencing platform was used to explore the key differentially expressed genes involved in the pathogenesis of MAFLD.

**Methods:** In the present study, we firstly fed male C57/BL6N mice with high fat and high fructose (HFHF) diet for 19 weeks to induce MAFLD model while setting up a normal diet control group (Chow).
Background: Cellular senescence is a state where cells resist growth signals and apoptosis, ceasing proliferation. This leads to a prolonged ‘zombie-like’ state, impacting regenerative tissues like the liver. Senescent cells undergo metabolic shifts, affecting liver function. Heterogeneity among the senescence characteristics makes targeting senescent cells difficult. This study focuses on the link between telomerase inhibition-induced senescence and liver cell metabolism.

Methods: Primary hepatocytes or hepatocyte-derived organoids were cultured in vitro. Both were treated with 20 μM BIBR-1532 (telomerase inhibitor) for 12-72 hours. Senescence was assessed through SA-β-galactosidase, immunofluorescence, immunoblotting (p53, p21, γH2AX), and senescence-associated secretory phenotype (SASP) markers. Cellular bioenergetics were measured using the XF eSea-horse analyzer.

Results: BIBR-1532 increased phosphorylation of histone (γH2AX), a DNA damage marker, by 10-fold (p<0.001), and SA β-galactosidase activity by 11-fold (p<0.001) (Figure 1A). Arrested proliferation is an important feature of senescence cells and the primary hepatocytes have limited proliferation in 2D culture. To overcome this limitation, we validated the results in hepatocyte-derived organoids and observed similar findings (Figure 1A). Coincided with DNA damage, BIBR1532 stabilized p53, increased p21 levels, and SASP expression. In contrast to the studies in immortalized cell lines, telomerase inhibition initially (up to 24 hours of treatment) increased oxidative phosphorylation capacity, however, in the later senescence phase, the cellular bioenergetics became predominantly glycolytic (Figure 1B).

Conclusion: BIBR-1532 (telomerase inhibitor) induces senescence phenotype in mouse primary hepatocytes. Cellular bioenergetic capacity transitions from oxidative phosphorylation to glycolysis in BIBR-1532 treated hepatocytes, which may affect the hepatocytes’ response to toxins and inflammation.

Abstract Submission No. 100503 O-0293

PAK1 protects against nonalcoholic fatty liver disease via suppression of PPARγ

Hanzhi Xu1,2, Xun Qiu1,2, Yawen Tan1,2, Zhoucheng Wang1,2, Xiao Xu1, Kai Wang1,2

1Institute of Organ Transplantation, Zhejiang University Hangzhou China, 2Key Laboratory of Integrated Oncology and Intelligent Medicine of Zhejiang Province, Department of Hepatobiliary and Pancreatic Surgery, Affiliated Hangzhou First People’s Hospital, Zhejiang University School of Medicine Hangzhou China

Background: Nonalcoholic fatty liver disease (NAFLD) is the most common chronic liver disease worldwide characterised by an increase in hepatic accumulation of triglycerides. The p21 activated kinase 1 (PAK1) participates in the regulation of many cellular processes such as cell growth, survival and migration. However, the role of PAK1 in NAFLD remains unclear. This study aims to identify the function and mechanism of PAK1 in NAFLD.

Methods: The mice fed high fat or methionine and choline deficient L-amino acid diet and mouse hepatic cells treated with oleic acid were used to detect the change of PAK1 in the progression of NAFLD/NASH. Lentivirus, siRNA and small molecular chemicals were used to overexpress or suppress targeted genes in mouse hepatic cells. Triglyceride content was detected by oil red O staining. The gene expression was measured by western blotting and RT-qPCR. In vivo investigations have shown that inhibiting FTO’s enzymatic

Abstract Submission No. 100543 O-0294

Antioxidative Activity of Orange Water Kefir to Improve Liver Tissue in The Hyperlipidemic Rat Model

Rafik Prabowo1,2, Saosanti Mariana3

1Region General Hospital of Rokan Hulu Riau Indonesia, 2Faculty of Medicine, Universitas Islam Indonesia Special Region of Yogyakarta Indonesia, 3Faculty of Industrial Technology, Universitas Islam Indonesia Special Region of Yogyakarta Indonesia

Background: This research aims to know the antioxidative activity of orange water kefir drink to improve oxidative stress of liver tissue and lipid profile level in the hyperlipidemic rat model.

Material and Methods: This research used 30 rats divided into 3 groups (K+, K-, B). Group of K+ and B were given quail egg yolk for the first 4 weeks to make hyperlipidemia condition. For the next 4 weeks, K+ and K- groups were only fed ad libitum. Group B was given an orange water kefir drink with a dose of 5 ml/200grBW. Orange water kefir drink was made by good manufacturing product (GMP) standards and the procedure for making water kefir. All of this intervention was administered to rats with the sonde method. Blood sampling was taken to measure lipid profile (Total Cholesterol/TC and High-Density Lipoprotein/HDL) and the animal model was terminated to get liver organs to measure the Malondialdehyde (MDA level) and Superoxide Dismutase (SOD activity). Data will be expressed as mean ± SD and significant differences when the P value < 0.05.

Results: The Mean of TC (mg/dL) was 203.50±0.96 (K+), 77.80±1.52 (K-), and 131.32±2.38 (B). Mean of HDL (mg/dL) was 25.98±0.58 (K+), 82.31±0.88 (K-), and 51.50±1.24 (B). MDA level (nmol/g) was 11.80±0.17 (K+), 2.5±0.12 (K-), and 4.56±0.12 (B). The mean of SOD activity (%) was 21.43±2.52 (K+), 71.43 ± 3.91 (K-), and 71.42 ± 2.70 (B). The results showed significant differences between all groups after the intervention with orange water kefir drink (P<0.001).

Conclusion: The antioxidative activity of orange water kefir drink has been proven to improve oxidative stress of liver tissue and lipid profile levels in the hyperlipidemic rat model.

Abstract Submission No. 100552 O-0295

Entacapone Abrogate Steatotic Liver Disease Progression by Modulating FTO Gene Expression

Sunita Giri1, Vijay Kumar1

1Institute of liver and biliary sciences Delhi India

Background: Steatotic Liver Disease (SLD) is a metabolic dysfunction-associated liver disease that arises in the context of obesity and metabolic disorders, and poses a substantial health burden. The fat mass- and obesity-associated (FTO) gene, initially identified through genome-wide association studies, is positively correlated with obesity and metabolism in both humans and mice. However, the metabolic regulation of FTO in SLD remains unclear. Furthermore, in silico and in vitro investigations have shown that inhibiting FTO’s enzymatic
activity of FTO leads to the dysregulation of genes involved in energy metabolism. In this study, we used entacapone, a drug for Parkinson’s disease treatment and known as an FTO inhibitor, to alleviate SLD in a murine obesity model.

Methods A murine obesity model was established by feeding C57BL/6J male mice a high-fat, high-calorie (HFHC) diet for 13 weeks, with some mice receiving intraperitoneal entacapone injections of varying doses and durations. Key metabolic parameters, including glucose and insulin tolerance, liver histology, serum biochemistry, adiponectin and leptin levels, and hepatic FTO expression, were meticulously assessed using microscopy, ELISA, RT-qPCR, immunohistochemistry, and western blotting.

Results: Compared with their entacapone-treated counterparts, HFHC-fed mice exhibited impaired glucose regulation, increased body weight, heightened liver index score (p<0.0001), and periportal fibrosis. Disease severity, reflected by SLD activity scores (p<0.0001), emphasized exacerbated liver pathology in the HFHC-fed group. Elevated serum biochemical markers, such as alanine transaminase, aspartate transaminase, triglycerides, and total cholesterol, were evident in HFHC-fed mice. In contrast, the entacapone-treated group displayed more favorable metabolic profiles (p<0.01).

Additionally, entacapone-treated mice demonstrated elevated serum adiponectin levels and reduced serum FTO expression (p<0.0001). In contrast, higher levels of serum leptin and FTO were observed in HFHC-fed mice. RT-qPCR, immunohistochemical analysis, and western blot validation confirmed increased FTO expression (p<0.0001) in the livers of HFHC-fed mice compared to that in the treatment groups.

Conclusion: These findings suggest that entacapone has the potential as a therapeutic agent for the management of obesity and SLD by interfering with the progression of MASLD. This study introduced entacapone as a repurposing drug to address metabolic liver disorders associated with obesity, thereby offering novel therapeutic avenues in this demanding medical domain.

METTL14 Promotes Liver Glucose Production and Liver Steatosis in Obesity by RNA m6A modification

Xiao Zhong1, 2, 6, Qiantao Zheng2, 3, Qianqian Kang2, 3, Zhiguo Zhang2, 3, Decheng Ren1, Liangyou Rui1, 2, 5

1Department of Infectious Diseases, Hunan Key Laboratory of Viral Hepatitis, Xiangya Hospital, Central South University Changsha China, 2Department of Molecular & Integrative Physiology, University of Michigan Medical School Ann Arbor USA, 3Elizabeth Weiser Caswell Diabetes Institute, University of Michigan Michigan USA, 4Department of Medicine, University of Chicago Chicago USA, 5Division of Gastroenterology and Hepatology, Department of Internal Medicine, University of Michigan Medical School Ann Arbor USA, 6National Clinical Research Center for Geriatric Disorders, Xiangya Hospital, Central South University Changsha China

Hepatic glucose production (HGP), a pivotal process mediated by glycolysis and gluconeogenesis, maintains energy metabolism during fasting and exercise. However, an excessive amount of HGP can lead to diabetes. Glucose-6-phosphatase (G6pase) is a key enzyme that regulates HGP through both glycolysis and gluconeogenesis. N6-methyladenosine (m6A) modification controls RNA processing, trafficking, decay, and translation. Mettl14 binds to Mettl3 and forms a m6A transferase complex to modify RNA. Recent studies have shown that the Mettl3/Mettl14/m6A pathway plays a crucial role in health and disease, but its function in HGP remains unknown. Here, we identify Mettl14 as m6A writer for G6pase transcripts. Obesogenic factors increase expression of Mettl14 and Mettl3 in hepatocytes, thereby increasing RNA m6A modification in the liver. Deletion of hepatic Mettl14 decreases hepatic gluconeogenesis, liver glucagon response, and blood glucose in mice with HFD-induced obesity while not altering HFD-induced obesity. Mettl14 overexpression has the opposite effect. Moreover, Mettl14-deficient male mice are resistant to HFD-induced liver steatosis, and Mettl14 deficiency does not alter liver insulin and glucagon signaling. Notably, HFD feeding increases liver G6pase transcript m6A content and G6pase levels. Overexpression of Mettl14 increases, whereas ablation of Mettl14 decreases G6pase transcript m6A content in hepatocytes. Deletion of Mettl14 decreases G6pase transcript stability and translation, thereby lowering G6Pase levels, gluconeogenesis, and glycogenolysis. These data unravel a hepatic Mettl14/m6A/G6pase/gluconeogenesis and glycogenolysis axis contributes to increased hepatic glucose production and diabetes progression in obesity.

Abstract Submission No. 100780

Role of Serum Ferritin Level in The Diagnosis of Non-Alcoholic Fatty Liver Disease

Mohammad AZAM1, A Arbab Chowdhury1, M Anisur Rahman1

1BIRDEM ACADEMY Dhaka Bangladesh

Background: Non-alcoholic fatty liver disease (NAFLD) is characterized by excessive liver fat accumulation and is a major cause of progressive liver disease. Serum ferritin is a biochemical parameter which is elevated in several clinical conditions including both acute and chronic liver diseases. It may indicate hepatic inflammation, necrosis and fibrosis progression in NAFLD due to its association with iron buildup and inflammation.

Aims: To assess the role of serum ferritin as an effective marker in the diagnosis of NAFLD.

Materials and Methods: This cross sectional study was conducted at Bangladesh Institute of Research and Rehabilitation in Diabetes, Endocrine and Metabolic disorders (BIRDEM) General Hospital, Dhaka on patients attending department of Gastrointestinal, Hepatobiliary and Pancreatic Disorders (GHPD). Purposive sampling technique was applied to enroll the subjects according to selection criteria. Statistical significance were set at 0.05 level and confidence interval at 95% level.

Result: This study included 206 patients. They were divided into two groups on the basis of ultrasonogram of abdomen. Among them 136 patients had NAFLD (Group-A) and 70 patients had normal liver (Group-B). Serum ferritin level was measured in all patients. The mean±SD of serum ferritin was significantly higher among Group-A (326.88±203.94) than Group-B (57.23±14.55) (p<0.001). ROC analysis for serum ferritin level yielded an AUC of 0.993. Sensitivity, specificity, PPV, NPV and accuracy at cut off value 77 ng/ml were 94%, 97%, 94%, 97%, 96%; at 78.5 ng/ml were 95%, 97%, 94%, 95%, 96%; at 81.5 ng/ml were 98%, 95%, 92%, 99%, 97%; at 82.6 ng/ml were 94%, 98%, 99%, 89%, 95% and at 86 ng/ml were 92%, 98%, 90%, 92% and 90% respectively. The cut-off value of serum ferritin ≥81.50 ng/ml showed the highest accuracy.

Conclusion: The findings of this study suggest serum ferritin is an important biochemical test of NAFLD.

INFODEMIOLOGY STUDY

FATTY LIVER DISEASE: A RETROSPECTIVE INFODEMIOLOGY STUDY

Aaron Lemuel Ong1, Janus Po Ong2, Eric David B. Ornos3
1Philippine General Hospital Cebu Philippines, 2Philippine General Hospital Manila Philippines, 3University of the Philippines Manila Philippines

Background: Non-alcoholic fatty liver disease (NAFLD) is a prevalent and growing health concern globally, coinciding with the rise of metabolic disorders. Understanding the search patterns related to NAFLD can provide insights into public interest for this condition. This research aims to analyze global online interest using Google Trends.

Methods: Google Trends data for search terms related to fatty liver over a period of five years was downloaded and analyzed. Spearman’s rank-order correlation correlated NAFLD, diabetes and obesity prevalence data, GDP per capita and internet penetration rate with search volume index.

Results: There was a significant reduction in online search interest during the COVID-19 pandemic (2020) however, there was an increase of approximately 30% in search terms related to fatty liver post-pandemic. The Latin American countries had the highest search volume when using the search term “fatty liver disease” while predominantly North American and Middle Eastern countries used “NAFLD” as a search term. The NAFLD search volume index was positively correlated with obesity prevalence and GDP per capita while searches for fatty liver disease correlated with the NAFLD prevalence in these respective countries. Countries with high liver cirrhosis-related mortality also searched “fatty liver” the most. Although majority of countries had above average internet penetration rate, this did not approach statistical significance.

Conclusions: The study found that the global online interest in fatty liver disease is increasing especially in regions where NAFLD prevalence is high and the use of Google Trends can be utilized as an infodemiologic tool.

A COMPARISON OF THE KNOWLEDGE AND PRACTICES ON NON-ALCOHOLIC FATTY LIVER DISEASE AMONG PHYSICIANS

Aaron Lemuel Ong1, Janus Po Ong2
1Philippine General Hospital Manila Philippines, 2Philippine General Hospital Manila Philippines

Background: NAFLD affects 25% of the population worldwide and poses a significant economic burden. It is important that physicians are aware of the burden of NAFLD and its appropriate management. This study aims to assess the knowledge, attitude, and practices of physicians towards NAFLD in a tertiary hospital.

Methods: A cross-sectional study was done using an online questionnaire distributed to all specialists, fellows and residents in Internal and Family Medicine in Philippine General Hospital.

Results: A total of 97 physicians participated in this online survey. Most of the respondents were from family medicine followed by internal medicine. In terms of knowledge, only half of participants correctly identified the true prevalence of NAFLD and just 20% were aware of the available tools to stage fibrosis in NAFLD. On multiple regression, only number of NAFLD patients seen per year seemed to correlate with knowledge but this did not reach statistical significance.

Despite most physicians agreeing that NAFLD may lead to cirrhosis, a third are not concerned about cirrhosis as a consequence of NAFLD and only half routinely screen for NAFLD in at-risk patients. Fibrosis risk assessment using predictive tools is almost never practiced and referral to specialists is only done occasionally. Majority however, routinely prescribe individualized diet and exercise regimens.

Conclusion: Despite the increasing burden of NAFLD, there is still a significant gap in the knowledge and practices among physicians. Reinforcement of guidelines should be shared to all physicians in order to improve diagnosis and management of this disease.

Lessons on Drug Development: A Literature Review of Challenges Faced in MASLD Clinical Trials

Joel Yeh Siang Chen1, Damien Chua1, Nguan Soon Tan1
1Lee Kong Chian School of Medicine Singapore Singapore

Background: Metabolic-dysfunction associated Steatotic Liver Disease (MASLD) is a leading liver disorder worldwide, resulting in both hepatic and systemic complications, notably cardiovascular diseases. Notwithstanding its profound impact on healthcare, current therapeutic strategies for MASLD primarily hinge on weight management — a task often challenging for patients — with no pharmaceutical solutions approved by the FDA to date.

Methods: We conducted a review of MASLD-focused clinical trials for 22 drugs (Phase 2 and beyond) listed on ClinicalTrials.gov as of 24th August 2022. Data collected encompassed trial identifiers, titles/ acronyms, duration, patient counts and diagnoses, trial outcomes, and associated side effects. Subsequently, drugs were grouped into five analytical categories: Hypoglycemic, Lipid-lowering, Bile-pathway, Anti-inflammatory, and a diverse set which included nutraceuticals.

Results: Challenges hampering progress in the MASLD drug landscape included limited data, challenging trial design and outcomes, and debilitating adverse events. These findings shed light on several key areas for improvement, including repurposing existing drugs, exploring drug combinations, adopting non-invasive outcome measures, advocating for standardization, addressing adverse reactions, and prioritizing precision medicine that duly accounts for the intricate heterogeneity of MASLD in clinical trials.

Conclusion: While every advancement in drug discovery invariably presents unique challenges, this study underscores the importance of drawing lessons from past experiences. Proposing strategic improvements based on prevailing data allow us to advance clinical trials towards uncovering effective therapeutic drugs for MASLD management.

Abstract Submission No. 100866

OMENTIN-1: IMPLICATIONS ON ITS ROLE IN DIABETES AND METABOLIC-ASSOCIATED FATTY LIVER DISEASE

Noel Salvoza1,2,3, Pablo Giraudi4, Silvia Gazzin2, Maria Melissa Milito2,3, Deborah Bonazza2, Silvia Palmisano4, Nicolet de Manzi2, Fabrizio Zanconati2, Alan Raseni2, Francesca Sirianni2, Claudio Tiribelli2, Natalia Rosso5
1Philippine Council for Health Research and Development - Department of Science and Technology Philippines Taguig Philippines, 2Fondazione Italiana Fegato - ONLUS Trieste Italy, 3Lee Kong Chian School of Medicine Singapore Singapore, 4Azienda Ospedaliero Universitaria di Trieste Italy, 5Department of Science and Technology Philippines Taguig Philippines

Background: Omentin-1 is an adipocytokine which is expressed in human omentum lipocytes and adipose tissue in vivo and in vitro. Omentin-1 is a 38 kDa protein which is a member of the fibrinogen-like family of proteins. Omentin-1 is known to be involved in the regulation of glucose, lipid and insulin metabolism. Omentin-1 has also been associated with obesity and type 2 diabetes in the past years.

Methods: A comprehensive literature review was conducted to analyze the role of Omentin-1 in diabetes and metabolic-associated fatty liver disease (MAF-LD). The databases PubMed, Scopus, and Web of Science were searched for relevant articles. The search terms included “omentin-1”, “diabetes”, “metabolic syndrome”, “fatty liver disease”, “liver cirrhosis”, and “non-alcoholic fatty liver disease.”

Results: The search resulted in 100 articles, of which 50 were relevant to the study. The majority of the studies found a significant association between Omentin-1 and metabolic diseases, including diabetes, obesity, and metabolic syndrome. Several studies also reported an association between Omentin-1 and non-alcoholic fatty liver disease (NAFLD) and liver cirrhosis.

Conclusion: Omentin-1 is a potential biomarker for metabolic diseases, including diabetes and fatty liver disease. Further studies are needed to clarify the role of Omentin-1 in the development and progression of these diseases.
Objectives: Obesity and diabetes are tightly linked to metabolic-associated fatty liver disease (MAFLD). Here, we explore the potential role of visceral adipose tissue (VAT) omentin-1, identified through in silico analysis, in the context of obesity-related MAFLD and diabetes.

Methods: Omentin-1 levels were measured in obese patients with biopsy-proven MAFLD and mice fed with high-fat diet (HFD). In vitro and/or ex vivo studies were conducted to investigate the effects of omentin-1 on MAFLD-related pathogenesis, including steatosis, inflammation, ER stress, oxidative stress, and glucose-insulin modulation. We also analyzed the levels of omentin-1 in diabetic patients before and after 1 year of bariatric surgery.

Results: VAT and plasma omentin-1 levels exhibit a significant stepwise reduction in MAFLD patients, depending on disease severity but independent of fibrosis status. Likewise, HFD-fed mice with histological signs of MASH exhibited significantly reduced omentin-1 levels compared to their control diet counterpart. In vitro and ex vivo experiments using fat-laden hepatocytes and VAT explants, respectively, showed that omentin-1 did not affect steatosis but significantly reduced TNF-α levels, ER stress, and oxidative stress. Furthermore, omentin-1 significantly decreased the mRNA expression of NF-κB and mitogen-activated protein kinases. Ex vivo VAT explants showed that D-glucose and insulin significantly reduced omentin-1 mRNA expression and protein levels. Notably, diabetic patients exhibited a significant increase in plasma omentin-1 levels one year following bariatric surgery.

Conclusions: Our findings suggest that reduced omentin-1 levels contribute to the development of diabetes and MAFLD. Therefore, further research is warranted to explore its role as potential therapeutic target and/or biomarker.

Non Alcoholic steatohepatitis examined by FAST score and colorectal carcinoma-A case-control study

Jishnu J¹, Kandasamy alias kumar E¹, Poppy Rejoice¹, Shafique A¹, Geetha D¹
¹Department of Medical Gastroenterology, Tirunelveli Medical College Tirunelveli India

Background: FAST score has been recently suggested for non-invasive detection of Non alcoholic steatohepatitis(NASH). We evaluated the relationship between Colorectal carcinoma(CRC) and co-existence of NASH detected by FAST scoring, as a risk factor.

Methodology: Patients with biopsy proven CRC were enrolled for the study group (n=53) and those without liver diseases or malignancies as control (n=53). The quantitative values of steatosis and fibrosis were measured using FibroScan. FAST score was calculated using the equation as carried out by Newsome et al. The optimal rule-out (FAST: ≤0.55) and rule-in (FAST: ≥0.78) cut-offs were applied. CAP, LSM, AST and FAST score values were compared between the two groups.

Results: Mean age was 53.7 years and 50.8 years for the case and control groups, respectively. 77.3 % of CRC (41/53) and 71% of control (38/53) had steatosis, defined by CAP ≥238dB/m (p=0.23). 68% of the case group (36/53) and 50% of the control (27/53) had fibrosis, defined by LSM ≥7.5kPa (p=0.002). Median AST was 76 for the case and 60 for the control (p=0.013). With rule-in cut off value for FAST score as ≥0.78, 63.4% of the case and 36.6% of the control had NASH with statistically significant p-value of 0.045. Odd ratio for association of NASH in CRC patients was 3.12, 95% CI 1.27-7.58, p=0.0015.

Conclusion: From our study, NASH has an association in CRC development. Further studies may help us to identify the role of NASH in tumorgenesis. Also, validating FAST scoring as a screening tool may help in early detection of steatosis and preventing complications.

Abstract Submission No. 101228

Sphingomyelin synthase 2 deficiency attenuates liver inflammation and fibrosis

Yingyun Gong¹, Xuan Ye¹, Wanzi Jiang¹, Hongwen Zhou¹
¹the First Affiliated Hospital of Nanjing Medical University Nanjing China

Objective: Sphingomyelin, a vital component of the plasma membrane, plays an indispensable role in maintaining membrane stability, fluidity, and cellular signal transduction. Sphingomyelin synthase 2 (SMS2) facilitates the transformation of ceramide to sphingomyelin, thereby regulating the sphingomyelin concentration within the plasma membrane. However, the exact function and underlying mechanism of sphingomyelin in nonalcoholic steatohepatitis (NASH) remain to be elucidated.

Methods: Wild-type (WT) and SMS2-knockout (SMS2-KO) male mice, aged nine weeks, were subjected to a Western diet (WD) (comprising 21.1% fat, 41% sucrose, and 1.25% cholesterol) and a high-sugar solution (containing 23.1 g/L d-fructose and 18.9 g/L d-glucose). Carbon tetrachloride (CCl4), diluted tenfold with corn oil, was administered intraperitoneally at a dosage of 2 μl (0.32 μg)/g of body weight once weekly for a duration of 12 weeks.

Results: Compared to WT mice, SMS2-KO mice exhibited a decrease in both plasma membrane sphingomyelin and total liver sphingomyelin. WD/CCl4-treated SMS2-KO mice displayed mild hepatic steatosis in both plasma membrane sphingomyelin and total liver sphingomyelin. WD/CCl4-treated SMS2-KO mice displayed mild hepatic steatosis in both plasma membrane sphingomyelin and total liver sphingomyelin. WD/CCl4-treated SMS2-KO mice displayed mild hepatic steatosis. WD/CCl4-treated SMS2-KO mice displayed mild hepatic steatosis.

Conclusion: The depletion of SMS2 mitigates liver injury in WD/CCl4-induced NASH mice due to a decrease in the inflammatory response and TGFβ1-mediated collagen accumulation. This suggests that SMS2 deficiency may exert a protective effect against the progression from simple steatosis to NASH.

Intestinal IL-33 exacerbates NASH by increasing gut microbiota-derived TMAO synthesis

Qin NING¹, Suping Hai¹, Xitang Li¹, Wenhui Wu¹, Qiang Gao¹, Binghui Yu¹, Erliang Xie¹, Xiaojing Wang¹
¹Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology Wuhan China

Background: Gut microbiota and its metabolites play a critical role in the development of non-alcoholic steatohepatitis (NASH) through the gut-liver axis. IL-33 is highly expressed in the intestine and regulates intestinal and extraintestinal diseases. Herein, we investigated the role of intestinal IL-33 in NASH.

Abstract Submission No. 101281
O-0305

Intestinal IL-33 exacerbates NASH by increasing gut microbiota-derived TMAO synthesis
Methods: IL-33 knockout mice and their control mice were fed 60% high-fat diet (HFD) for 24 weeks to establish NASH models. 3,3-dimethyl-1-butanol (DMB), a kind of choline analogue, was administered to inhibit gut microbiota-derived trimethylamine N-oxide (TMAO) synthesis. Fecal microbiota transplantation was carried out to study the role of IL-33-related gut microbiota alterations in NASH. Feces and serum were analyzed by 16S rRNA sequencing and metabolomics. Human intestinal epithelial cell line, Caco-2, and spleen naïve CD4+ T cells were used for in vitro studies.

Results: The expression of intestinal IL-33 was increased in NASH. IL-33 knockout improved NASH progression by alleviating intestinal barrier leakage and gut microbiota dysbiosis, with the decrease level of TMAO. Inhibition of TMAO synthesis by DMB reduced hepatic injury in NASH. Intracellular IL-33 inhibited the expression of intestinal barrier-related genes, directly damaging the intestinal barrier. Extracellular IL-33 promoted Th1 differentiation and function leading to the pro-inflammatory environment in the gut. Transplantation of gut microbiota reversed NASH phenotypes.

Conclusion: These findings suggest that intestinal IL-33 increases gut microbiota-derived TMAO synthesis and aggravates NASH progression. Targeting intestinal IL-33 and its related microbiota may provide a potential strategy for treating NASH.
To identify high-confidence diagnostic markers we isolated and analyzed the RNA content of exosomes from different MAFLD mouse models and human patients. For establishing disease stage specific mouse liquid biopsy-based exosome RNA content signatures we collected serum from mice being exposed for 1, 6 or 8 weeks CDHFD, 8, 14, 20 or 26 weeks to Western Diet or respective controls, exposed to normal chow for the indicated times. Exosomes were precipitated, RNA isolated and high quality NGS libraries for sequencing were prepared. The same approach was applied to human patient serum from patients with liver biopsy verified disease stage. Data was in depth analyzed with a focus on interspecies conserved high confidence biomarkers, which were validated by qPCR on independent patient samples. Pathway analysis shows that the mRNA content of isolated exosomes reflects important gene expression changes associated with the metabolic syndrome. We can identify liver related, but also cardio-vascular and bacterial changes associated with this disease. We then pinpointed 16 specific and reliable mRNA biomarker, which we could validate in mice and man.

Hepcidin alleviates hepatic steatosis through inhibiting PERK signaling pathway

Xiaofan Wang1, Yingying Liu1, Chao Xie1, Tianhui Liu1, Ping Wang1, Lin Liu1, Xu Fan1, Jidong Jia1, Min cong1

1Beijing Friendship Hospital, Capital Medical University, Beijing China

Background: Hepcidin is a crucial protein regulating iron homeostasis, while hepatic steatosis was more severe in hepcidin knockout mice in our previous study. The aim of this study is to investigate the role and mechanism of hepcidin modulating lipid metabolism in metabolic-associated fatty liver disease (MAFLD).

Methods: A mouse model of fatty liver was established by high fat diet (HFD) or methionine choline deficiency diet (MCD) feeding. Mice were injected with recombinant adeno-associated virus carrying hepcidin (AAV-Hamp) or green fluorescence protein. AML12 cell line was used to investigate the mechanism of hepcidin in regulating lipid metabolism.

Results: Treatment with AAV-Hamp significantly improved hepatic steatosis in both HFD and MCD mice, accompanied by a decrease in triglyceride (TG) content, lipid droplet formation and changes in mRNA and protein related to lipid synthesis and lipolysis. However, hepcidin did not significantly improve liver inflammation and fibrosis in MCD mice. In an in vitro model of lipid deposition using AML12 cells stimulated with oleic acid, hepcidin administration reduced the expression of lipid synthesis-related mRNA and protein, consistent with the in vivo experiments. Specifically, hepcidin decreased the expression of fatty acid synthase (FASN) and protein kinase RNA-like ER kinase (PERK), one of the three endoplasmic reticulum stress sensors. Furthermore, intervention of the PERK signaling pathway with a PERK activator abolished the protective effect of hepcidin on lipid deposition by inhibiting FASN.

Conclusions: Hepcidin plays a protective effect in hepatic lipid metabolism by decreasing the expression of FASN through inhibiting PERK signaling pathway, thereby alleviating MAFLD.

C-reactive Protein and Nonalcoholic Fatty Liver Disease

Qin NING1, Qinghao Guo1, Yuan Zhan1, Meiwen Han1, Qianting Guan1, Fangfei Yan1, Jie Feng1, Dong Xi1

1Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan China

Background: C-reactive protein (CRP) was found to increase in patients with nonalcoholic fatty liver disease (NAFLD). However, the causal association between NAFLD and CRP need to be further assessed.

Methods: Baseline information of 202 subjects between were collected from Tongji Hospital. Univariable and multivariable binary logistic regression analyses were conducted to assess the association between CRP and NAFLD. Furthermore, summary-level data from GWAS was employed in MR analysis. Inverse variance weighted (IVW) method was the primary analytic approach to infer the causality. Then, the Cochran’s Q test and MR-Egger regression analysis were performed to determine the heterogeneity and pleiotropy, and the leave-one-out analysis was conducted to assess the stability of MR result.

Results: The retrospective study showed that CRP significantly increased in patients with NAFLD compared to non-NAFLD controls (2.40 vs 0.70, P<0.001). Multivariable logistic regression analysis revealed that elevated CRP was an independent risk factor for NAFLD (OR=1.141, 95%CI 1.007-1.294, P=0.039). Subsequently, a significant positive causality of CRP with NAFLD was observed by IVW method (OR=1.187, 95%CI 1.004-1.404, P=0.045). It was further confirmed by the results of weighted mode (OR=1.321, 95%CI 1.147-1.521, P=0.000), and weighted median (OR=1.341, 95%CI 1.132-1.589, P=0.000). Meantime, no causal effect of NAFLD on CRP. Horizontal pleiotropy was not found among instrument variables (IVs). Despite the presence of heterogeneity, the MR result was proved robust by leave-one-out sensitivity analysis.

Conclusion: CRP is significantly increased in patients with NAFLD and may serve as an independent predictor for the risk of NAFLD.

Abstract Submission No. 101423

Assessment of Liver Fibrosis with Transient Elastography in NAFLD Patients

Lajpat Rai1, Nazish Butt1, Ali Akbar1, Riaz Hussain1

1Jinnah Postgraduate Medical Center, Karachi Pakistan

Background: Transient elastography is a non-invasive technique for estimating liver fibrosis. There is limited data about the performance of TE in Pakistani patients with non-alcoholic fatty liver disease (NAFLD). The overall prevalence of NAFLD in Pakistan is 47%.

Method: A Cross-sectional study was undertaken at the Department of Gastroenterology, Jinnah Postgraduate Medical Centre, Pakistan. After obtaining ethical approval, all patients above the age of 18 years, with the diagnosis of NAFLD based on abnormal liver-function tests and ultrasound abdomen consistent with fatty liver were included in the study. All patients with hepatitis, hepatic malignancies, hepatobiliary infections, and biliary tract disease were excluded from the study. Fibrosis score was calculated through Elastography as F0-F1 (5.3-7.1 kPa, Normal); F2 (7.5-8.5 kPa, Mild/Grade-I); F3 (9.5-13.0 kPa, Moderate/Grade-II); and F4 (13.1-18.8 kPa, Severe/Grade-III).

Results: A total of 171 patients were enrolled in the study, from which 69 (40.35%) were male and 102 (59.64%) were female, with a mean age of 37.50 ± 9.74 years. Of these, 112 (65.49%) belonged to the lower socioeconomic class. One hundred and twenty-two (71.34%) patients had fatty liver on ultrasound and 49 (28.65%) had hepatomegaly.
with fatty changes. TE revealed that 69 (40.35%) patients had a score of F0-F1, 62 (36.25%) F2, 29 (16.95%) F3, and only 11 (6.43%) had a score of F4.

**Conclusion:** Detecting liver fibrosis at its early stages is crucial in preventing its progression to cirrhosis. Reversal of fibrosis is only possible if it is diagnosed as early as possible and managed with appropriate treatment.

**Exploring the Interplay of Hepatic Steatosis, Body Fat Ratio, and Hepatic Fibrosis in MAFLD**

**Tushar Prabhakar,1,2 Shiv Kumar Sarin,2, Manya Prasad2**

1Amrita School of Medicine Faridabad India, 2Institute of Liver and Biliary Sciences New Delhi India

**Background:** Hepatic fibrosis is a significant pathological condition with far-reaching implications for public health, often associated with hepatic steatosis and the overall distribution of body fat. This study encapsulates a comprehensive investigation aimed at elucidating the intricate relationship between hepatic steatosis, body fat ratio, and the development of hepatic fibrosis in patients with NAFLD. **Methods:** Data from hospital-based records of a tertiary specialty centre was collected for the period from April 2021 to August 2023. Transient elastography provided Liver Stiffness Measurement values, and cut-off for liver fibrosis was kept at 7.9 kPa. Continued Attenuation Parameter (CAP) value of more than or equal to 248 Db/m was defined as hepatic steatosis. Body composition analysis was performed using InBody 770 machine.

**Results:** A total of 586 MAFLD patients were studied of which 288 (49.1%) had some degree of liver fibrosis. Mean age was 46.6±13.1 years and 71.6% were males. Percent Body Fat was significantly higher in those with no liver fibrosis (33.8±9.5% vs 32.5±9.6%; p=0.031). When study subjects were stratified according to liver steatosis and total body fat percentage, it was observed that median liver fibrosis was 7.6kPa [IQR 5.1-20.6] in those with liver steatosis present & body fat percentage more than normal upper limit. In those with liver steatosis present but normal body fat percentage, liver fibrosis was 13.7kPa [IQR 8.8-62.9]. Liver fibrosis was significantly correlated to liver steatosis (-0.125; p<0.001), body fat percentage (-0.101; p=0.001), liver steatosis/body fat mass ratio (-0.108; p=0.001), BMI (0.113; p=0.001) and obesity degree (0.082; p=0.01).

**Conclusions:** MAFLD patients having central obesity (having higher visceral fat content) had higher tendency to develop hepatic fibrosis. Such patients may be more predisposed to having other metabolic ailments and strategies to decrease hepatic fat may benefit both liver and help prevent other metabolic diseases.

**IMPACT OF RENAMING NAFLD TO METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE (MASLD)**

**Erika Johanna P. Taada1, Stephen N. Wong1, Ann Margaret C. Navarroza1, Joseph Niño Espino1, Hyacinth C. Eviota1, Rene John D. Febro1, Jaqueline S. Arsena1, Salahudin C. Andam1, Maria Hosea C. Monfero1**

1University of Santo Tomas Hospital Manila Philippines

**Background:** The second-most recent change in steatosis nomenclature required 2/3 weight-metabolic criteria to be met and may lead to missed diagnosis in patients who develop weight-metabolic abnormalities later on. The metabolic-dysfunction-associated steatotic liver disease (MASLD) criteria requires only one criterion and may mitigate this. We aimed to characterize our steatotic patients into: 1) nonalcoholic fatty liver disease (NAFLD); 2.) MASLD only; 3.) NAFLD-MASLD; 4.) not NAFLD-MASLD.

**MATERIALS AND METHODS:** Consecutive patients with steatotic liver on ultrasound in a Hepatology clinic database from August 2007-July 2017 were included. Demographic, laboratories, AST/Platelet ratio (APRI), FIB4, and NAFLD fibrosis score (NFS) were compared between the groups.

**Results:** The 663 steatotic patients were categorized into: 60(9.9%) NAFLD, 326(49.2%) MASLD, 325(49%) NAFLD-MASLD, and 6(0.9%) not NAFLD-MASLD. Among patients meeting MASLD criteria, majority (80%) met ≥2 cardiometabolic criteria while only a minority (8.3%) satisfied only 1 criterion, of which overweight/obesity (79.6%) was most common. NAFLD-MASLD and MASLD patients had higher ALT, AST and platelet levels as compared to NAFLD and not NAFLD-MASLD patients (p<0.05). A higher probability of advanced fibrosis was seen in MASLD only compared to the other groups using APRI. There was a trend for more no/minimal fibrosis patients in the NAFLD and not NAFLD-MASLD groups compared to the MASLD and NAFLD-MASLD groups using non-invasive liver fibrosis tests.

**Conclusions:** Majority (82%) of patients with steatosis on ultrasound meet MASLD criteria. Serial follow-up is needed to determine if patients who do not meet MASLD criteria now will meet it in the future.
Conclusions: In the NAFLD microenvironment, cell-cell communication via FGFRs is hopefully a promising therapeutic target. The Hedgehog signaling pathway may be the essential mechanism that plays a counterpart role.

Abstract Submission No. 101825

CD36-mediated uptake of oxidized LDL induces ferroptosis and dysfunction in DNTregs in NAFLD

Yuxiong Wei1-4, Shimeng Zheng1-2, Xiyu Wang1-2, Guangyong Sun1, Dong Zhang6

1Medical Research Center, Beijing Institute of Respiratory Medicine and Beijing Chao-Yang Hospital, Capital Medical University Beijing China, 2Department of Gastroenterology, Beijing Chao-Yang Hospital, Capital Medical University Beijing China, 3Beijing Laboratory of Oral Health, Capital Medical University School of Basic Medicine Beijing China, 4Immunology Research Center for Oral and Systemic Health, Beijing Friendship Hospital, Capital Medical University Beijing China

Background: Inflammation plays a pivotal role in the development of NAFLD. CD3 TCR7αβ/CD4 CD8 double negative immune-regulatory T cells (DNTregs) are important for maintaining liver immune homeostasis. However, during NAFLD progression, intrahepatic DNTregs have decreased cell survival and immunosuppressive function, which lead to aggravated liver proinflammation. However, the reasons and underlying mechanisms that cause the changes of DNTregs during NAFLD progression are still unknown.

Methods and results: We analyzed DNTregs in PBMCs from NAFLD patients and in NAFLD mouse models with serum biochemical test index. Correlation analysis showed a significant negative correlation between serum oxLDL levels and both the survival and functional molecule expression levels of DNTregs. Moreover, stimulating DNTregs with oxLDL, we noticed decreased cell survival and immunosuppressive function of DNTregs accompanied by an increased DNTreg ferroptosis. Ferroptosis inhibitors were able to regain the immunosuppressive function of DNTregs. Further investigation revealed that CD36 is the primary regulator of oxLDL-mediated ferroptosis in DNTregs. CD36 knockout significantly rescued oxLDL-induced ferroptosis in DNTregs. Meanwhile, CD36 predominantly enhanced ferroptosis in DNTregs by upregulating ACSL4 expression. CUT&TAG experiments confirmed the oxLDL-induced upregulation of Hif-1α, which bound to the ACSL4 promoter region, thereby induced CD36-mediated ferroptosis. Finally, transferring CD36-/- DNTregs into NAFLD mice, we observed a significantly reduced ferroptosis, enhanced survival and immune regulation of CD36-/- DNTregs compared with those of WT DNTregs. This improvement of DNTregs resulted in a notable enhancement of the therapeutic efficacy against NAFLD.

Conclusions: Specifically targeting CD36 to prevent ferroptosis of DNTregs may provides a novel therapeutic approach for NAFLD.

Therapeutic target identification of MAFLD through patient transcriptomic-based in vivo RNAi screen

Yong-An Lee1, Dong Yeul Lee1, Chee Chong Lek1, Gao Rong4, Yee Siang Lim1, Yun-Shen Chan2, Yock Young Dan3, Mei Chin Lee1, Huck Hui Ng1, Torsten Wuestfeld4

1Genome Institute of Singapore (GIS) Singapore Singapore, 2Guangzhou Regenerative Medicine and Health Guangdong Laboratory Guangzhou China, 3National University of Singapore Singapore Singapore, 4National Cancer Centre Singapore Singapore Singapore, 5Nanyang Technological University Singapore Singapore

Backgrounds: Metabolic dysfunction-associated fatty liver disease (MAFLD) has become a significant global health concern, yet it remains underrepresented with limited identified effective therapeutic targets. Although analyzing patient transcriptomics provides insights into dysregulated genes with therapeutic potential, MAFLD is a complex condition involving intricate interactions among multiple organs. Consequently, the identification of effective therapeutic targets necessitates an innovative approach. To meet this challenge, we have devised a novel approach utilizing patient transcriptome-based in vivo RNAi screening to identify potential therapeutic targets for MAFLD.

Method: Dysregulated genes in patient liver tissues were identified through RNA sequencing. A pooled-shRNA library was constructed to target these genes and hydrodynamically introduced into mouse hepatocytes. Mice were divided into treated (high-fat diet) and control (normal diet) groups. Genomic DNA was collected from liver samples post-diet for quantifying shRNA abundance. Therapeutic target candidates were determined by identifying enriched shRNA in treated group mice.

Results: We identified four primary candidates as the most promising targets following a screening process, warranting further validation as-says. Silencing these target genes resulted in a notable reduction in disease progression, specifically in fibrosis formation. One of the four targets underwent additional validation to elucidate its mechanism of
action, revealing that the knockdown of this target significantly enhances lipid metabolism.

**Conclusion:** Our findings highlight the efficacy of our approach in identifying novel targets for MAFLD therapeutics. Suppression of the identified target gene expression significantly alleviated disease progression. This study contributes valuable insights to the discovery of novel MAFLD therapeutics.

Abstract Submission No. 200098

**MicroRNA-411-5p targets the EIF4G2 / FOXO3 axis to alleviate lipid deposition in MAFLD**

Zhiping Wan1, Xiaquan Liu1, Xiaoen Yang1, Hong Cao1, 2, Hong Deng1

1Department of Infectious Diseases, the Third Affiliated Hospital, Sun Yat-sen University Guangzhou China, 2Guangdong Provincial Laboratory of Liver Disease Research, the Third Affiliated Hospital, Sun Yat-sen University Guangzhou China

**Background:** Abnormal lipid deposition is an important driver of metabolic dysfunction-associated fatty liver disease (MAFLD) progression. MicroRNA-411-5p (miR-411-5p) and eukaryotic translation initiation factor 4e2 (EIF4G2) are related to abnormal lipid deposition, but the mechanism is unknown.

**Methods:** A high-fat and high-cholesterol diet (HFD) or a choline-deficient, L-amino acid-defined, high-fat diet (CDAHFD) was used to construct the MAFLD rat or mouse models. Adeno-associated virus type 8 carrying EIF4G2 shRNA were injected into the tail vein to downregulate EIF4G2. MiR-411-5p mimic was used to upregulate the expression of miR-411-5p.

**Results:** The miR-411-5p level was decreased in both MAFLD rats and mice, and was negatively correlated with the liver triglycerides and the degree of liver injury. Up-regulation of miR-411-5p reduced fatty acid synthesis to alleviate lipid deposition. Moreover, EIF4G2 was confirmed to be a target gene of miR-411-5p, and miR-411-5p downregulated the expression of EIF4G2. Down-regulation of EIF4G2 expression reduced fatty acid synthesis and alleviated lipid deposition in palmitic acid-induced steatosis hepatocytes. Importantly, down-regulation of EIF4G2 in the liver alleviated liver damage and abnormal lipid deposition in MAFLD mice. Besides, EIF4G2 regulated the expression of forkhead box class O 3 (FOXO3), and up-regulation of miR-411-5p or down-regulation of EIF4G2 both lead to reduced expression of FOXO3.

**Conclusions:** Up-regulation of miR-411-5p inhibits EIF4G2 to reduce the expression of FOXO3, thereby inhibiting fatty acid synthesis and alleviating abnormal lipid deposition in MAFLD. MiR-411-5p is beneficial for improving MAFLD and EIF4G2 is expected to become a therapeutic target for MAFLD.

**FTZ inhibits the hepatic lipid deposition by TFF3/PPAR α/AMPK signaling pathway in diabetes mice**

Yi qi Yang1, Quan you Liu1, Hong yan Huo1, Jia li Wu1, Zi yang Lin1, Hai bo Tan1, Jiao Guo1

1Guangdong Pharmaceutical University guangzhou China

**Background:** Trefoil Factor 3 (TFF3) TFF3 is a novel liver glycolipid metabolism regulatory factor that can maintain the homeostasis in the body by PPARα/AMPK signaling pathway. FTZ as a representative formula of the “Tiao Gan Qi Shu Hua Zhuo” method in prevention and treatment of glycolipid metabolism diseases, the inner mechanism is unknown.

**Methods:** 1. Animals: db/db and C57BL/6J mice (induced by 40mg/kg STZ and HFD) were used in our study. FTZ (1-2 g/kg) and Atorvastati (5mg/kg) were used for 12 weeks treatment. 2. L02 cells: Palmitic acid (0.25 mmol/L) and Glucose (6 mmol/L) were used to stimulate the L02 cells, followed by FTZ intervention for 24h. And the indicators including TC, TG, LDL-C, HDL-C, ALT and AST were detected by biochemical test kits. H&E and Oil Red staining methods were used to evaluate the histopathological changes and lipid accumulation in liver. IHC and WB methods were used to detect the TFF3, PPARα, p-AMPK/AMPK, p-ACC/ACC and CPT-1α levels.

**Results:** FTZ can significantly reduce the TC and TG content, and improve the liver function, inhibit liver lipid deposition, and significantly increase the protein levels of TFF3, PPARα, p-AMPK, p-ACC and CPT-1α in the liver and L02 cells.

**Conclusion:** FTZ can inhibit the hepatic lipid deposition, which could be related with TFF3/PPARα/AMPK signaling pathway, and further accelerate fatty acids β oxidation to decrease lipid accumulation. The study provides a new perspective and experiment basis for the prevention and treatment of metabolic diseases.

**Enhancing liver health in type 2 diabetes: CD26 inhibitors & Glycine max antioxidants synergy**

Anand Krishna Singh1, Purnima Tripathi1

1Shri Vaishnav Vidyapeeth Vishwavidyalaya Indore India

**Aims:** Non-alcoholic fatty liver disease (NAFLD) is the predominant chronic liver ailment globally, afflicting over half of type 2 diabetes mellitus (T2DM) patients due to exacerbated insulin resistance, oxidative stress, and inflammatory disruptions. A promising avenue for T2DM treatment involves leveraging the incretin hormone GLP-1. Dipeptidyl peptidase-IV (DPP-IV/CD26) inhibitors, sourced from Glycine max’s phenolic-rich fraction, may exhibit pleotropic effects via the presence of incretin hormone receptors in diverse tissues, including the liver. Our study explores the potential impact of DPP-IV inhibitors with antioxidant capabilities on NAFLD in a T2DM rat model.

**Methods:** Wistar rats underwent T2DM induction via a high-sucrose diet and dexamethasone. Biochemical, toxicological, and histological parameters were assessed. Evaluations encompassed serum DPP-IV inhibition, glycosylated hemoglobin, HOMA-IR, hepatic lipid peroxidation, SGOT, SGPT, and tissue antioxidants. Serum lipid profiles were examined to correlate with the antiperoxidative effects of Glycine max’s phenolic-rich fraction.

**Results:** Diabetes induction via corticosteroid and high sucrose diet was confirmed by HOMA-IR (2.5%), HOMA-β (36.3%), and HOMA sensitivity (44.3%). In-vitro DPP-IV inhibition assay demonstrated 63.1±2.8%, while serum activity was 41.9±1.3%. The DPP-IV inhibitors lowered aminotransferases (SGOT & SGPT) and alkaline phosphatase, elevated insulin, and reduced HbA1c. Triglyceride and cholesterol levels normalized. Glycine max extract exhibited superior antioxidant capacity, safeguarding against lipid peroxidation, and preserving liver histoarchitecture, emphasizing positive outcomes post-DPP-IV inhibitor treatment.

**Conclusions:** DPP-IV inhibitors along with antioxidant properties improve insulin sensitivity, reduce oxidative stress and toxicity which lead to improve liver dysfunction in T2DM. These findings also suggest that GLP-1 in liver has beneficial effects on NAFLD.
Abstract Submission No. 200201

The potential mechanism of methotrexate induced liver injury in MAFLD: in silico analysis

Yongqiang Xiong1, Bo Wang1, Na Huang2, Ren Li1, Shu Zhang6
1Department of Geriatric Digestive Surgery, the Second Affiliated hospital of Xi’an Jiaotong University Xi’an, Shaanxi China, 2Core Research Laboratory, the Second Affiliated Hospital of Xi’an Jiaotong University Xi’an, Shaanxi China, 3Experimental Teaching Center for Clinical Skills, the Second Affiliated Hospital of Xi’an Jiaotong University Xi’an, Shaanxi China

Background: The putative liver toxicity of methotrexate should be evaluated in the pathogenesis and natural history of liver disease, especially metabolic associated fatty liver disease (MAFLD). We initially identify the potential effects of methotrexate in MAFLD based on network toxicology and molecular docking technology.

Methods: The drug toxicity information was obtained from ProTox-II and ADMETlab 2.0. The potential targets related to methotrexate and MAFLD were identified through ChEMBL, STITCH, GeneCards and OMIM databases. The core genes were analyzed using STRING and Cytoscape, gene ontology (GO) analysis, and Kyoto Encyclopedia of Genes and Genomes (KEGG) pathway enrichment. The interactions between methotrexate and these core genes were confirmed by AutoDock Vina.

Results: ProTox-II and ADMETlab 2.0 confirmed the hepatotoxicity of methotrexate, and 22510 disease target genes and 541 drug target genes were identified from the database. Venn diagram showed 189 common related potential target genes between Methotrexate and MAFLD. Among these genes, 20 core targets were identified by STRING and Cytoscape. Further analysis of GO and KEGG pathway showed that genes related to methotrexate induced MAFLD mainly distributed in cancer and proteoglycans in cancer pathway and estrogen signaling pathway. AutoDock Vina confirmed the intensity of binding between methotrexate and the core target genes. The binding ability was relatively higher in ACLY, LDHA, HMGCR, ITGB3, MMP2, BCL2, and CASP3, than other target genes.

Conclusion: The core genes identified here maybe can serve as targets for the prevention and treatment of MAFLD in patients taking methotrexate.

Abstract Submission No. 100089

Vitamin E versus Placebo in the Treatment of NASH: a Multicenter, Randomized, Double-blind Study

Shijun Ping1, Yu Song1, Minghua Zheng4, Huiping Sheng2, Jing Wang4, Yongfeng Yang2, Xiaohong Chi2, Jinjun Chen4, Fangping He2, Xiaotang Fan16, Jie Li1, Shufei Zang3
1Hongzhuang Normal University Affiliated Hospital Hangzhou China, 2Nanjing Drum Tower Hospital Nanjing China, 3Shanghai Fifth People’s Hospital Shanghai China, 4The First Affiliated Hospital of Wenzhou Medical University Wenzhou China, 5General Hospital of Ningxia Medical University Ningxia China, 6The Affiliated Traditional Chinese Medicine Hospital of Southwest Medical University Lanzhou China, 7The Second Hospital of Nanjing Nanjing China, 8Guangdong Provincial Hospital of Chinese Medicine Guangzhou China, 9Nanshan Hospital Guangzhou China, 10The First Affiliated Hospital of Xijing Medical University Urumqi China

Background: Despite the proven efficacy of long-term high-dose vitamin E (800IU) for the treatment of non-diabetic patients with non-alcoholic steatohepatitis (NASH), potential risks hinder its application. The efficacy and safety of a lower dose of vitamin E for NASH treatment is unclear.

Methods: This was a multicenter, randomized, double-blind, placebo-controlled study of non-diabetic patients with biopsy-proven NASH. Patients were randomly assigned to receive oral vitamin E (300mg about 450 IU) or placebo. The primary outcome was an improvement in hepatic histology. The exploratory secondary endpoint was improvement in liver fibrosis by at least one stage and no worsening of NASH.

Results: A total of 124 patients were randomly assigned to receive vitamin E (58 patients) or placebo (66 patients). In the modified ITT population, 29.3% of those who received vitamin E demonstrated an improvement in histology (43.6% in PPS) compared with 14.1% (17.7% in PPS) in the placebo group (p = 0.040 in modified ITT, p = 0.0071 in PPS). An improvement in the exploratory secondary endpoint was observed in 25.9% (38.5% in PPS) of the vitamin E group and 19.6% (19.6% in PPS) of the placebo group (p = 0.16 in modified ITT, p = 0.048 in PPS). Serious adverse events were reported in a similar proportion of patients across groups but were not considered to be related to treatment.

Conclusions: Oral vitamin E administered at a dose of 300mg daily resulted in a significantly higher histologic improvement in non-diabetic NASH patients and was safe and well tolerated for NASH treatment.

The greater impact of PNPLA3 polymorphism on liver-related events in Japanese NAFLD

Yuya SEKO1, Kanji Yamaguchi1, Yoshito Itoh1, Takashi Okanoue1, Hirokazu Takahashi2, Miwa Kawanaka1, Saiyu Tanaka3, Atsushi Nakajima4
1Kyoto Prefectural University of Medicine Kyoto Japan, 2Saiseikai Saitama Hospital Saitama Japan, 3Saga University Saitama Saitama Japan, 4Nara City Hospital Nara Japan, 5Nara City Hospital Nara Japan, 6Yokohama City University Graduate School of Medicine Yokohama Japan

BACKGROUND & AIMS: PNPLA3 rs738409 has been associated with an increased risk of liver-related events in patients with non-alcoholic fatty liver disease (NAFLD). In this study, we investigated the epidemiology of NAFLD and the impact of PNPLA3 on prognosis in Japan.

Methods: A longitudinal multicenter cohort study, the JAGUR study, includes 1550 patients with biopsy-proven NAFLD in Japan. We performed genetic testing and evaluated outcomes from this cohort. Liver-related events were defined as hepatocellular carcinoma (HCC) and decompensated liver cirrhosis events.

Results: During follow-up (median [range], 7.1 [1.0-24.0] years), 80 patients developed HCC, 104 developed liver-related events, and 59 died of any cause. The 5-year rate of liver-related events for each single-nucleotide polymorphism was 0.5% for CC, 3.8% for CG, and 5.8% for GG. Liver-related deaths were most common (n=28); only 3 deaths were due to cardiovascular disease. Multivariate analysis identified carriage of PNPLA3 CG/GG (hazard ratio [HR] 16.04, p=0.006) and FIB-4 index >2.67 (HR 10.70, p<0.01) as predictors of liver-related event development. No HCC or liver-related death was found among patients with PNPLA3 CC. There was a significantly increased risk of HCC, liver-related events, and mortality for CG/GG versus CC, but no difference between the CG and GG genotypes.
Conclusions: In Japanese individuals, the main cause of death from NAFLD is liver-related death. The greater risk of liver-related events incurred by PNPLA3 G allele was shown in Japan. Risk stratification for NAFLD in Japan is best accomplished by integrating PNPLA3 with the FIB-4 index.

Abstract Submission No. 100116

Dissecting the Impact of Sex and Menopause on Steatotic Liver Disease: A Population-Based Study
Carolin Schneider1, Helen Huang2, Yelyzaveta Markova1, Jan Clusmann1, Jule K Adams1, Kate Townsend Creasy3, Eleonora Scorletti1, Christian Trautwein1, Yusuf Yilmaz4, Kai Markus Schneider1
1RWTH Aachen University Aachen Germany, 2Department of Genetics, Perelman School of Medicine, University of Pennsylvania, Philadelphia USA, 3Department of Nursing, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA 19104, USA, 4Department of GastroenterologySchool of Medicine, Recep Tayyip Erdoğan University Rize Turkey

Background: Steatotic liver disease (SLD) is affecting approximately 20-30% of the general population. However, data regarding sex differences are limited.

Methods: Therefore, we conducted a population-based study using the UK Biobank. Participants who underwent liver magnetic resonance imaging (MRI) and provided information on their sex/menopausal status were included. Logistic regression models were used to assess the association between sex differences in 18,135 men, 6159 premenopausal women, and 11,069 postmenopausal women, and steatosis on MRI, adjusting for age and BMI.

Results: Our results revealed that men had a higher prevalence of steatosis than women (34.5%), regardless of menopausal status. Postmenopausal women exhibited a higher prevalence of steatosis than premenopausal women (17.4% premenopausal women 20.9% in postmenopausal women), suggesting that menopause may increase the risk of steatosis. Additionally, we observed distinct clinical and laboratory profiles in male and female patients with simple steatosis. FIB4 levels were elevated in 8.4% of premenopausal women, 33.7% of postmenopausal women, and 35.9% of men. Homozygous carriers of TM6SF2 rs58549296 or PNPLA3 rs738409 were at increased risk of steatosis on MRI across all three groups. Shorter sleep duration increased the risk of steatosis in pre-menopausal women, while alcohol intake increased the risk in men only.

Conclusion: Our findings indicate that sex and menopausal status are important factors to be considered when studying hepatic steatosis. These results emphasize the need for personalized, sex-specific approaches to prevent steatosis. Further research is needed to elucidate the mechanisms underlying sex differences in, identify therapeutic targets, and develop sex-specific strategies for medical interventions.

Abstract Submission No. 100204

The correlation between LDL level and the development of NAFLD
MOHAMED MAHBOOB ALI1
1ADVANCED MEDICAL AND DENTAL INSTITUTE(AMDI) GEORGETOWN Malaysia

Background and Aims: NAFLD is a type of liver pathology that is associated with obesity, high cholesterol, Diabetes Mellitus, hypertension and genetics. The end result of NAFLD is liver cirrhosis and hepatocellular carcinoma(HCC). The aim of this study is to examine the correlation between LDL levels with the development of NAFLD.

Method: This is a retrospective study where a total of 1000 NAFLD patients were included. Variables such as age, sex, ethnicity, BMI, comorbidities, smoking status, liver function test and fasting serum lipid were recorded. Data from the years 2015 to 2020 were analyzed using the software empower stats version 5.0. Multivariate non-parametric analysis of the mean data was studied using the MANOVA test with a confidence interval (CI) of 95%. Receiver operating characteristic (ROC) curves were plotted to study the correlation between LDL and NAFLD. The area under the curve (AUC) was calculated and the DeLong test was used to determine the significance of the data.NAFLD was defined using liver ultrasound criteria such as liver brightness, vascular blurring, deep attenuation, and hepatorenal echo contrast. The scans were performed by the trained ultra-sonographer to reduce the operator bias.

Results: The level of LDL in both men and women was statistically significant in the development of NAFLD.ROC analysis for both sexes was performed and AUC for LDL was significantly higher in the NAFLD patients.
Conclusion: The level of LDL is significantly higher in NAFLD patients of both sexes and can be utilized as an early biomarker for the development of NAFLD.

Liver Fibrosis Tests and Outcomes of Bariatric Surgery in Morbidly Obese Patients with MASLD

Parinda Prathyajuta1, Thaninee Prasoppokakorn1, Kessarin Thanapirom1, Pattharasai Kachornvitaya1, Kanokwan Sonsiri1, Chonlada Phathong1, Arth Khemtong1, Suthep Udomsawaengsup1, Somrat Treeprasert1
1King Chulalongkorn Memorial Hospital, Thai Red Cross Society Bangkok Thailand

Background: MASLD is common among morbidly obese patients, but data on NITs for liver fibrosis assessment is limited. We aimed to validate NITs for predicting liver fibrosis and post-bariatric surgery outcomes.

Methods: In a single-tertiary-center retrospective cohort, we studied morbidly obese adults with biopsy-proven MASLD undergoing bariatric surgery between 2011 and 2022 (LRYGB/LSG). Follow-up exceeded 1 year. The primary outcome was NITs’ performance in predicting liver fibrosis, including LSM, FIB-4, NFS, APRI, and BARD scores. Secondary outcomes included biochemical and anthropometric changes.

Results: Among 193 patients, 103(53.4%) were female, mean age 36.3±10.9 years. Mean BMI was 47.7±14.4 kg/m², and 78(40.4%) had diabetes. Of these, 58(30.1%) had liver fibrosis(≥F1), and 9(4.7%) had significant fibrosis(≥F2). NITs showed low diagnostic accuracy for liver fibrosis (AUROC: LSM 0.38, FIB-4 0.59, NFS 0.53, APRI 0.50, BARD 0.51). After a median 1.9-year follow-up, LSM significantly decreased post-surgery (7.8 to 5.5 kPa, p=0.001). APRI and NFS improved (0.21 to 0.18, -0.773 to -1.395, p<0.001), while FIB-4 and BARD scores increased (0.52 to 0.60, 2 to 3, p<0.001) over a median 2.9-year follow-up (Figure). Anthropometrically, %TWL and BMI decreased significantly (30.8% to 28.5%, p=0.04, and 47.7 to 35.1, p<0.001). LRYGB had higher %TWL than LSG (30.8% vs. 28.5%, p=0.040). Biochemical parameters (AST, ALT, albumin, platelets, LDL-cholesterol, and triglycerides) improved significantly post-surgery. Subgroup analysis (n=27) showed LSM improvement>20% from baseline correlated with %TWL>30% (p=0.041).

Conclusion: Bariatric surgery improved long-term clinical/biological outcomes, though NITs demonstrated limited diagnostic accuracy for baseline liver fibrosis. Further research is needed to assess new NITs for monitoring liver fibrosis in morbidly obese patients.

Intelligent Diagnosis of Non-alcoholic Fatty Liver Disease Based on Multi-modal Ultrasound Features

Gangqiao Xie1,2,3, Yong-Sheng Xia4, Shun-Ping Chen4, Rui Wang4, Xingyue Wei1, Lijie Huang2, Zhiqiang Li2, Qiong He2, Ming-Hua Zheng2, Jianwen Luo4, Lai Wei5
1Hepatopancreatobiliary Center, Beijing Tsinghua Changgung Hospital, Tsinghua University Beijing China, 2Department of Biomedical Engineering, School of Medicine, Tsinghua University Beijing China, 3School of Clinical Medicine, Tsinghua University Beijing China, 4Department of Ultrasonography, The First Affiliated Hospital of Wenzhou Medical University Wenzhou China, 5MAFLD Research Center, Department of Hepatology, The First Affiliated Hospital of Wenzhou Medical University Wenzhou China, 6Key Laboratory of Diagnosis and Treatment for The Development of Chronic Liver Disease in Zhejiang Province Wenzhou China

Background: NAFLD is a prevalent chronic liver disease worldwide. The gold standard for NAFLD and at-risk non-alcoholic steatohepatitis (NASH) diagnosis is invasive liver biopsy. Therefore, there is an urgent need to develop non-invasive techniques for diagnosing key histological components of NAFLD and at-risk NASH.

Methods: Ninety-four patients with biopsy-proven NAFLD were included. A total of 262 features were extracted from an iLivTouch system, which utilizes multi-modal ultrasound techniques for diagnosing key histological components of NAFLD and at-risk non-alcoholic steatohepatitis (NASH).

Conclusions: The diagnostic performance of the iLivTouch system is promising for the non-invasive diagnosis of NAFLD and at-risk NASH. Further studies are needed to validate the system in larger populations and clinical settings.
system, ultrasound (US) images, and medical records by quantitative US techniques and US radiomics. A logistic regression model was developed for feature selection, and support vector machine (SVM) was used as the classifier for NAFLD diagnosis. Five-fold cross-validation was used to evaluate the classification performance.

**Results:** Multi-modal US features can accurately diagnose key histological components of NAFLD and at-risk NASH. The AUC values are 0.91 (95% CI, 0.75-1.00) for steatosis S2-S3 (≥ S2), 0.85 (95% CI, 0.74-0.99) for steatosis S3, 0.80 (95% CI, 0.71-0.88) for ballooning grade 2, 0.73 (95% CI, 0.57-0.81) for lobular inflammation grade 2-3 (≥ 12), 0.82 (95% CI, 0.28-0.85) for fibrosis grade 1-4 (≥ F1), 0.73 (95% CI, 0.59-0.78) for fibrosis grade 2-4 (≥ F2), 0.76 (95% CI, 0.58-0.88) for fibrosis grade 3-4 (≥ F3), and 0.81 (95% CI, 0.62-0.91) for at-risk NASH, respectively.

**Conclusions:** Multi-modal US features can accurately diagnose key components of NAFLD and at-risk NASH. With continued validation, they may be promising for evaluating the severity of NAFLD, diagnosing at-risk NASH, and dynamically assessing NASH resolution.

**Prevalence of Fatty liver disease in the Middle East and North Africa: A Systematic Review**

**Zobair Younossi1,2, Pegah Golabi1,2, James M. Paik2,3, Soroor Owrami2, Yusuf Yilmaz2, Mohamed El-Kassas2,4, Khalid Alswat5, Saleh AlQahtani6,7**

1The Global NASH council, Center for Outcomes Research in Liver Disease Washington, DC United States, 2Beatty Liver and Obesity Research Program, Inova Health System Falls Church, VA United States, 3Department of Gastroenterology, School of Medicine, Recep Tayyip Erdoğan University Rize Turkey, 4Department of Endemic Medicine, Faculty in Medicine, Helwan University Cairo Egypt, 5Liver Disease Research Center, Department of Medicine, College of Medicine, King Saud University Riyadh Kingdom of Saudi Arabia, 6Division of Gastroenterology & Hepatology, Johns Hopkins University Baltimore, MD United States, 7Organ Transplant Center of Excellence, King Faisal Specialist Hospital & Research Center Riyadh Kingdom of Saudi Arabia

**Background:** Nonalcoholic fatty liver disease (NAFLD) is part of the spectrum of fatty liver disease which is closely associated with type 2 diabetes (T2D) and other metabolic abnormalities. We assessed the prevalence of NAFLD among the general population and diabetics in the Middle East and North Africa (MENA) region using systematic review.

**Method:** We searched PubMed and Embase for articles published between 1990-2023 according to PRISMA. Each country’s NAFLD prevalence in the general population and in T2D patients was predicted by using multivariable meta regression model (global burden of disease-GBD 2019). Input data were extracted from our systematic review, GBD and NCD Risk Factor Collaboration. Confidence intervals were constructed by using prediction intervals with the Delta method.

**Results:** Meta-analytic pooling estimated NAFLD prevalence is 39.43% in the general population and 68.71% in T2D patients. NAFLD prevalence has increased from 35.42% (2008-2016) to 46.20% (2017-2020). Using GBD-2019, 141.51 million NAFLD prevalent cases were expected in the MENA region. The highest number of NAFLD cases were expected in Egypt (25.71 million), Türkiye (23.33 million), Iran (19.85 million), with the lowest cases from Bahrain (0.33 million). Estimated NAFLD prevalence exceeded 40% in 10 of 21 countries with the top countries being Kuwait (45.37%), Egypt (45.0%), Qatar (44.4%), and Jordan (43.3%). Furthermore, 24.96 million cases of NAFLD with T2D were expected in the MENA region.

**Conclusion:** Prevalence of NAFLD in the general population and among T2D is very high and growing necessitating urgent need to develop public policy to deal with this growing burden.

**Riding the Wave of Name-Change: Prevalence, Clinical Profile and Outcomes of NAFLD, MAFLD, and MASLD**

Laurence Laure1, Ian Homer Cua1, Juliet Cervantes1, Marie Antoinette Lontok1, Marianne Linley Sy-Janairo1, Ma. Regina Dimaculangan1, Ma. Felina Siray1, Maxine Andrea Garcia1

1St. Luke’s Medical Center- Global City Taguig Philippines

**Background:** The evolving renamed Non-Alcoholic Fatty Liver Disease (NAFLD) to Metabolic-Associated Fatty Liver Disease (MAFLD) and, subsequently, to Metabolic Dysfunction-Associated Steatotic Liver Disease (MASLD) has prompted a comparative investigation into these diagnostic criteria. This study aimed to identify its prevalence, clinical profile, and their outcomes.

**Methods:** Employing a five-year cross-sectional design, we collected data from our Liver Bank, including individuals diagnosed with hepatic steatosis Ultrasound, CT Scan, or MRI. We collected demographic data, metabolic and liver profiles, fibrosis scores, liver-related complications, and all-cause mortality.

**RESULTS:** A total of 201 patients (57.2% male) were included. Most patients were NAFLD-MAFLD-MASLD-overlap (50.25%). Alcohol ingestion was seen predominantly in the MAFLD only group (95%). Overall, triglycerides levels have a median of 139 mg/dl (29-375 mg/dL) with a significant difference across groups (p = .007§). Cirrhosis was present (22.61%), which varied significantly across patient categories (p = .030), where 44.4% of these, seen in MAFLD-only group. Cirrhosis outcomes had density rate of 3.45, while HCC stands at 4.15, where this was highest in the MAFLD+MASLD overlap group at 14.7%. The Kaplan Meier survival curve, at day 49, MAFLD-only had higher survival probability (76%, 95% CI 0.565-1.00) compared to NAFLD+MAFLD-MASLD (69%, 95% CI 0.461-1.00). All three and their overlaps were associated with increased all-cause mortality in individuals with Liver cirrhosis and HCC.

**CONCLUSION:** Patients excluded under the NAFLD definition, yet encompassed by MAFLD and MASLD, demonstrated an increased susceptibility to adverse liver-related outcomes. The nomenclature change appeared to enhance the clinical utility of these definitions.

**EUS-guided assessment of metabolic liver disease in patients with morbid obesity**

Rafael Romero-Castro1, Paula Fernandez-Alvarezz1, Maria Tous-Romero1, Felix Conde-Martin1, Alvaro Gutierrez-Domingo1, Victoria A. Jimenez-Garcia1, Eduardo Dominguez-Adame1, Patricia Cordero-Rubio1, Francisco Bellido-Muñoz1, Manuel Rodriguez-Tellez1, Angel Cañedo-Alvarez1, Juan J. Rios-Martin1, Isabel Carmona-Soria1

1Virgen Macarena University Hospital Seville Spain

**Background:** Bariatric surgery patients have a higher prevalence of metabolic associated- steatotic liver disease (MASLD). Percutaneous liver biopsy has technical difficulties and non-invasive markers are not very accurate in this population.
Aims: Evaluate the efficacy and safety of EUS-guided bilobar liver biopsy plus EUS-guided portal pressure gradient measurement in diagnosing MASLD and its correlation with non-invasive test.

Methods: Suspected MASLD by liver ultrasound or fatty liver index (FLI) score > 60. Demographic, anthropometrics, blood test, non-invasive serological markers (FLI, NAFLD, HEPAMET, APRI, FIB-4) and transient elastography (TE) with XL probe variables were evaluated.

Results: The prevalence of MASLD was 69%, metabolic dysfunction-associated steatohepatitis (MASH) 54.5%, and fibrosis (F1-F2) 12.6%. EUS-guided portal pressure gradient median was 4 mmHg, 9/33 (28%) patients had a gradient≥ 6 mmHg. MASLD patients showed higher levels of fibrosis determined by transient elastography (TE), of steatosis evaluated by coefficient attenuated parameter (CAP) and portal vein pressure, although they were not statistically significant. No differences were detected in FIB-4, NAFLD and HEPAMET scores according to MASLD.

The quality of liver biopsies was deemed adequate with a median of 7 portal spaces. There were observed 2 mild adverse events in 2 patients, one mild abdominal pain and one atrial fibrillation, successfully treated by medical therapy.

Conclusions: The prevalence of MASLD was high in morbid obesity patients. EUS-guided portal pressure gradient and EUS-guided liver biopsies seem safe and accurately evaluate the presence of portal hypertension and the underlying metabolic liver disease.

Abstract Submission No. 100619

Variability of Knowledge About Fatty Liver Disease: A Survey of Physicians from Asia

Zobair Younossi1, Janus Ong1, Hirokazu Takahashi1, Yusuf Yilmaz1, Yuichiro Eguchi1, Mohamed El-Kassas1, Ming-Hua Zheng1, Jian-Gao Fan1, Ming-Hua Zheng1, Jian-Gao Fan1, Vincent Wai-Sung Wong1, Khalid Aswat1, Yuichiro Eguchi1, Vincent Wai-Sung Wong1, Khalid Aswat1, Saleh Alqahtani1

1The Global NASH council, Center for Outcomes Research in Liver Disease Washington United States

Background: Despite the growing burden of fatty liver disease (FLD), there is low awareness and knowledge about the disease across different regions of the world. Our aim was to assess knowledge about FLD physicians in Asian countries.

Methods: Two specifically designed knowledge surveys containing 54-59 items were developed by the Global NASH Council members, one for GI/Liver specialists (hepatologists and gastroenterologists) and one for non-specialists (endocrinologists, primary care providers (PCPs), others). The surveys focused on terms such as FLD, NAFLD, NASH, and other related terms. Physicians from the Asian region completed the surveys using an approved electronic data collection form.

Results: There were 1482 physicians from 15 Asian countries who completed the survey: 180 hepatologists, 469 gastroenterologists, 115 endocrinologists, and 718 PCPs/other specialties. Their median practice duration was 12 years (IQR 4-24 years), 81% were hospital-based and 10% clinic-based physicians. Availability of diagnostic methods for fatty liver (imaging, liver biopsy) was the highest among hepatologists (39%-93%) and the lowest among PCPs (18%-80%) (all p<0.05). Practice guidelines were the most common primary source of latest knowledge about the disease for all the specialties (mean 43%) followed by national or international conferences (mean 16%) although Internet was the second most common source for PCPs (30%).

Disease knowledge related to epidemiology, pathogenesis, diagnostic tests, treatment, and understanding of the causes of death was higher among hepatologists than GIs (mean 68% vs. 61% correct answers) and higher among endocrinologists than PCPs (mean 73% vs. 63% correct) (both p<0.01). In multivariate analysis, the hepatology specialty (vs. GI), a hospital-based practice, seeing a greater number of affected patients per year, and using medical conferences or journals as a primary source of knowledge about the disease were independently predictive of a greater proportion of correct answers among specialists from Asian countries (all p<0.05). Similarly, the endocrinology specialty (vs. PCP) and a greater number of affected patients in the practice were associated with higher knowledge scores while using Internet as a primary source of knowledge about the disease was associated with lower knowledge scores (p<0.05) among non-specialists from Asia. Although 39%-73% survey completers believed that very few (<10%) patients have symptoms, the vast majority (78%-89%) believed that patients suffered from impaired quality of life.

Conclusions: Despite growing burden of FLD in Asia, a gap remains about disease knowledge and awareness. Better implementation of guidelines via conferences at society meetings in Asia may improve this knowledge gap.
Abstract Submission No. 100689

Diagnostic Performance in Detecting MASH with Fibrosis Stage 1 or Higher Using Machine Learning

Shun-ichi Wakabayashi1, Takefumi Kimura1, Tadanobu Iwadare1, Taiki Okumura1, Hiroyuki Kobayashi1, Yuki Yamashita1, Ayumi Sugira3, Satoru Joshita1,2, Takeji Umemura1

1Shinshu University School of Medicine, Division of Gastroenterology and Hepatology Matsumoto Japan, 2Yodakubo Hospital Nagawa Japan, 3Sato Hospital Nakano Japan

MASH, evolving from MASLD, is linked to liver cirrhosis and hepatocellular carcinoma. Early detection of early-stage fibrosis MASH is pivotal for timely intervention. This study sought to design a supervised machine learning (ML) model for predicting mild fibrosis MASH using routine blood data and to evaluate its diagnostic capabilities.

From 2003 to 2022, we analyzed 436 MASLD patients who had liver biopsies at our center. We characterized early stage MASH as Fibrosis ≥1. Supervised ML models, including Logistic Regression; LR, Support Vector Machine; SVC, Random Forest; RF, XGBoost, LightGBM, were trained on clinical and blood test data at biopsy. The cohort was split into a Training group (n=370) and a Test group (n=93). ML was employed on the Training set, and its diagnostic efficacy was gauged in the Test set through AUROC, Sensitivity, and Specificity.

The average age was 56, with 44% males. We observed 353 early-stage fibrosis MASH instances (F0: 83, F1: 198, F2: 55, F3: 99, F4: 28). Among 32 clinical and blood markers at biopsy, the RF model showcased the best prediction (AUROC=0.81). After implementing feature engineering, the RF model, using BMI, HbA1c, ALT, fasting glucose, and age+AST, outperformed others in the Test set (AUROC=0.84, Sensitivity=0.76, Specificity=0.86), exceeding APRI (AUROC 0.75) and FIB-4 (AUROC 0.72).

In conclusion, the RF model, with five clinical parameters, showed notable accuracy in identifying early-stage MASH.

Genetic Variants of Metabolic Dysfunction Associated Fatty Liver Disease from Taiwan Biobank

Xia-Rong Liu1, Yun-Zheng Gao1, Yi-Ting Chen1, Szu-Ching Yin1, Tzu-I Chen1, Mei-Hsuan Lee1

1Institute of Clinical Medicine, National Yang Ming Chiao Tung University Taipei City Taiwan

Background and Aims: The large-scale study aimed to investigate the risk factors and genetic variants associated with metabolic dysfunction-associated fatty liver disease (MASLD).

Methods: The study included 101,450 participants who underwent whole-genome genotyping throughout the Taiwan Biobank. All participants were non-drinkers and tested seronegative for HBsAg and anti-HCV antibodies. MASLD was defined by a fatty liver index ≥30 and the presence of at least one cardiometabolic risk factor. Participants with a fatty liver index <30 were categorized as non-steatotic liver disease. Logistic regression models were utilized to estimate the odds ratios (ORs) with 95% confidence intervals (CIs).

Results: Among the total population, 31389 (30.9%) had MASLD, while 70061 (69.1%) were individuals without steatotic liver disease. Individuals with MASLD showed significant positive associations with increased triglyceride levels, metabolic syndrome, central obesity, and cardiovascular disease (p<0.001). In addition, variants in the PNPL3, TM6SF2, and GCKR genes were found to be associated with MASLD, with the adjusted ORs (95% CI) of 1.73 (1.64-1.84), 1.22 (1.14-1.29), and 1.06 (1.02-1.11), respectively. Individuals with a higher number of risk alleles had an increased likelihood of having MASLD compared to non-steatotic liver disease. Participants with 4 risk alleles and 5 to 6 SNP risk alleles exhibited adjusted ORs of 1.19 (1.13-1.25) and 1.46 (1.39-1.54), respectively, when compared to those with 0 to 3 risk alleles.

Conclusions: Individuals with a greater number of risk alleles were more likely to have MASLD, emphasizing the importance of risk consultations for obesity-related comorbidities.

Results of triple therapy for NAFLD in Mongolia

Amsaranaa Jazag1,2,3,4, Erdenebayar Gonchig1, Baatarkhuu Oidov1, Enkhuyta Damba2-3, Buren-Ochir Tsakhurtsumur2, Tegshjargal Amarjargal1, Nandintsetseg Natsagdorj1, Urangoo Bayasgalanbaatar1

1MASLD, Mongolian Association for the Study of Liver Diseases Ulaanbaatar Mongolia, 2Otoch Manramba University Ulaanbaatar Mongolia, 3Happy Veritas Hospital Ulaanbaatar Mongolia, 4GLU Ulaanbaatar Mongolia

Background: Although it is well noted that hepatitis caused by viruses have recently decreased in Mongolia, it is expected that liver steatosis and cirrhosis related to unhealthy lifestyles will increase. Therefore, we conducted a study to determine the results of the triple therapy of NAFLD for the first time in our country.

Methods: Before treatment, the degree of steatosis was determined using the Fibrotouch / transient elastography/ device and patients with higher than normal values of steatosis were included, and then a triple medical therapy and lifestyle modifications were recommended for 1 month, and a second measurement was performed after treatment. The treatment was performed at the outpatient clinic of Happy Veritas Hospital. Treatment consisted of atorvastatin 20-40 mg once a day, ursodeoxycholic acid 250 mg 2-3 times a day, vitamin E 400 IU, 2 capsules per day after meals.

Results: 64 patients showed a decrease in fatty liver of 98.4%, and decrease in CAP values varied between 2 and 168 db/m respectively. Steatosis decreased in n=60 (93.7%) patients by at least one stage, 3% of patients (2.0%) whose steatosis reduced but the liver stiffness increased. The decrease in CAP values varied between 2 and 168 db/m respectively. Steatosis decreased in n=60 (93.7%) patients by at least one stage, 3% of patients (2.0%) whose steatosis reduced but the liver stiffness increased.

Conclusion: Triple therapy that consisted of lifestyle modifications plus statins, vitamin E and ursodeoxycholic acid was highly effective in Mongolian NAFLD patients.
Prevalence and characteristics of lean MAFLD in patients with diabetes: a multicenter study

weixia sun1,2, ling li3
1Southeast University Nanjing China, 2Department of Endocrinology, School of Medicine, Zhongda Hospital, Southeast University Nanjing China

Background: Metabolic associated fatty liver disease (MAFLD) is associated with obesity and type 2 diabetes (T2DM). Little is known about the prevalence and characteristics of MAFLD patients with normal body mass index and T2DM.

Comparing 1.5T and 3.0T MRI for Assessing Hepatic Steatosis with Proton Density Fat Fraction

Chia Yun Chang1, Chih horng Wu1
1Medical imaging, National Taiwan University Hospital, Taipei, Taiwan Taipei Taiwan

Background: Magnetic resonance spectroscopy (MRS) serves as a non-invasive method for assessing hepatic steatosis. However, it also presents shortcomings, including selection variability and spatial limitation. Proton density fat fraction (PDFF), a newly developed quantitative method for measuring liver fat across the entire liver, shows potential in replacing MRS.

There is no uniform protocol about PDFF, our study aims to compare the correlation between PDFF and MRS under the different magnetic fields.

Methods: 401 healthy liver donors of NTUH receiving pre-transplantation evaluation prospectively enrolled from August 2011 to September 2021. After 1:1 matching for age, gender and body mass index (BMI), 250 patients included in the study, evenly distributed in the two magnetic fields.

PDFF value measurements were taken from the six liver segments (S5, S6, S7, S8, medial and lateral). Correlations with MRS were separately analyzed, as well as the averages of 6 segments were also analyzed. Patients were categorized into high-fat and low-fat groups using a PDFF cutoff of 5%, and correlations were examined.

Results: The highest correlation was found in the average of the six segments in 3.0T (Spearman’s r value: 0.8945, p<0.05) and the lowest correlation in the lateral segment in 1.5T (Spearman’s r value: 0.7725, p<0.05). After grouping patients by fat content, the average of the six segments in 1.5T exhibited the highest correlation (Spearman’s r value: 0.9336, p<0.05), while the lateral segment in 1.5T displayed the lowest correlation (Spearman’s r value: 0.5096, p<0.05).

Conclusions: In our research, the average PDFF value of 6 segments has the highest correlation with MRS in both magnetic fields. And after grouping patients by fat content, 1.5T is better for the high-fat group and 3.0T is better for the low-fat group.
Metabolic dysfunction-associated steatotic liver disease and liver-related outcome

Sang Yi Moon¹, Yang Hyun Baek¹, Yeo Wool Kang¹, Minkook Son¹
¹Dong-A University College of Medicine Busan South Korea

Introduction: Compared to nonalcoholic fatty liver disease (NAFLD), the recently proposed metabolic dysfunction-associated steatotic liver disease (MASLD) has been suggested to better reflect the metabolic components of fatty liver disease (FLD). This study examines the occurrence of hepatocellular carcinoma (HCC) and liver cirrhosis-related complications in patients with and without MASLD, metabolic dysfunction, and alcohol-associated steatotic liver disease (MetALD).

Materials and methods: Using the Korean National Health Insurance database, we identified participants who underwent a health-screening program in 2010 and 2011 and retrospectively analyzed their data until 2019. The main objective was to ascertain the rate of newly diagnosed HCC and liver cirrhosis-related complications during the observation period for each patient group.

Results: Out of the 310,724 individuals, 108,996 (35.1%) were part of the MASLD group, 13,960 (4.5%) belonged to the MetALD group, and 187,768 (60.4%) were in the neither FLD group. When using the neither FLD group as the reference, the multivariable-adjusted hazard ratio (95% confidence interval) for HCC events was 1.34 (1.26-1.42) in the MASLD group and 1.48 (1.31-1.67) in the MetALD group, while the hazard ratios for liver cirrhosis-related complications were 1.31 (1.24-1.38) in the MASLD group and 1.73 (1.56-1.92) in the MetALD group.

Conclusions: Individuals with MASLD exhibit higher rates of HCC and liver cirrhosis-related complications compared to those without the condition.
GLP-1 receptor agonists (RA) like liraglutide and semaglutide are approved antidiabetic drugs and have shown to reduce weight and cardiovascular risks in multiple studies. Real-life data on the effect of these GLP-1RA in steatotic liver disease (SLD) are scarce.

**Methods:** Observational study examining liraglutide and semaglutide in SLD patients. Patients received therapy with liraglutide 0.6mg increased to 3.0mg daily or semaglutide 0.25mg weekly increased to 1mg subcutaneously for a period of at least 2 months. Elasticity using Fibroscan®, fat content using CAP (controlled attenuation parameter), weight and laboratory were recorded directly before, immediately after the end of therapy and after 6 months.

**Results:** 33 (17 female) patients were treated with GLP-1RA. 73% of patients were diagnosed with NAFLD, 16% with NASH and 11% with BASH. After 2 months of treatment with GLP-1RA, there was significant reduction in elasticity (median decrease 29.2% (+1.9kPa)) and significant decrease in CAP (median decrease 29.0% (+82dB/m)). Significant weight reduction was achieved (7.4% after two, 6.3% reduction six months post treatment). In 12 patients with elevated ALT, reduction was achieved in 9 patients after 2 months, stable after 6. The subgroup of women (10.7%, p=0.8) and those not suffering from diabetes showed a more pronounced weight reduction (10.2%, p=0.09) after 2 months. There was no significant difference between liraglutide (25) and semaglutide (8) patients. Both 1 patient with liraglutide (0.6%) and semaglutide (0.25%) patients were diagnosed with NAFLD, 16% with NASH and 11% with BASH. There were no significant differences in age, sex, occupation, or smoking history between the two groups. After treatment with empagliflozin, weight (76.91±6.4 vs. 73.52±6.8 kg, p=<0.001), BMI (22.52±4.6 vs. 21.47±4.6 kg/m², p=0.001), HbA1C (7.65±1.5 vs. 7.27±1.47%, p=0.012), AST (43.25±3.8 vs. 41.17±4.1 IU/L, p=0.001), ALT (56.04±7.7 vs. 52.53±7.5 IU/L, p=0.001), GCT (67.4±4.4 vs. 59.7±5.1 IU/L, p=0.001), total cholesterol (177.4±19.7 vs. 170.9±18.1 mg/dl, p=0.001), triglycerides (138.4±15.1 vs. 132.8±14.2 mg/dl, p=0.001), and LDL (109.6±16.7 vs. 103.7±17.1 mg/dl, p=0.001) significantly decreased. Additionally, the mean liver stiffness significantly decreased from baseline in the empagliflozin group (3.28±0.46 vs. 3.40±0.40 kPa, p=0.031), with a notable improvement in stages of liver stiffness among respondents.

**Conclusion:** Empagliflozin had a significant impact on liver fibrosis, weight, and liver function tests when used in patients with NASH and type 2 diabetes mellitus.

---

**Effect of Empagliflozin for the Treatment of Nonalcoholic Steatohepatitis in Patients with Type 2 DM**

*sarker sajjad¹,², Tareq Bhuyan¹*

¹MRC, FCPs Dhaka Bangladesh, ²BIRDEM general hospital Dhaka Bangladesh

**Background:** Non-alcoholic fatty liver disease (NAFLD) encompasses a spectrum of liver conditions, ranging from benign hepatic steatosis to the more severe non-alcoholic steatohepatitis (NASH), often leading to liver fibrosis. This study aims to assess the effects of empagliflozin on liver fibrosis in patients with nonalcoholic steatohepatitis (NASH) and type 2 diabetes mellitus.

**Methods:** This prospective, randomized, controlled, open-label study was conducted at the Department of GHPD, BIRDEM General Hospital, Dhaka, over a six-month period. Ninety patients with Type 2 diabetes mellitus (DM) and NASH were enrolled from the department’s outpatient population after obtaining informed written consent. They were randomly allocated into two groups: the empagliflozin group (Group A) and the control group (Group B) in a 1:1 ratio, with treatment allocation being open-label. Socio-demographic characteristics, clinical features, and laboratory investigations were assessed. Data was collected using a semi-structured questionnaire, and analysis was performed using Statistical Package for Social Science (SPSS) version 24.0.

**Results:** The mean age of respondents in the empagliflozin and control groups was 49.11±7.90 and 46.98±10.19 years, respectively, with a higher proportion of males in both groups (77.8% and 84.4%, respectively). There were no significant differences in age, sex, occupation, or smoking history between the two groups. After treatment with empagliflozin, weight (76.91±6.4 vs. 73.52±6.8 kg, p=<0.001), BMI (22.52±4.6 vs. 21.47±4.6 kg/m², p=0.001), HbA1C (7.65±1.5 vs. 7.27±1.47%, p=0.012), AST (43.25±3.8 vs. 41.17±4.1 IU/L, p=0.001), ALT (56.04±7.7 vs. 52.53±7.5 IU/L, p=0.001), GCT (67.4±4.4 vs. 59.7±5.1 IU/L, p=0.001), total cholesterol (177.4±19.7 vs. 170.9±18.1 mg/dl, p=0.001), triglycerides (138.4±15.1 vs. 132.8±14.2 mg/dl, p=0.001), and LDL (109.6±16.7 vs. 103.7±17.1 mg/dl, p=0.001) significantly decreased. Additionally, the mean liver stiffness significantly decreased from baseline in the empagliflozin group (3.28±0.46 vs. 3.40±0.40 kPa, p=0.031), with a notable improvement in stages of liver stiffness among respondents.

**Conclusion:** Empagliflozin had a significant impact on liver fibrosis, weight, and liver function tests when used in patients with NASH and type 2 diabetes mellitus.
Impact of single nucleotide polymorphisms on long-term prognosis in non-obese MASLD

Michihiro Iwaki1, Kobayashi Takashi2, Nogami Asako2, Yuya Seko2, Kanji Yamaguchi3, Miwa Kawanaka3, Saiyu Tanaka3, Hirokazu Takahashi4, Yoshito Itoh5

1Yokohama City University Graduate School of Medicine Yokohama Japan, 2Kyoto Prefectural University of Medicine, Graduate School of Medical Science Kyoto Japan, 3Kawasaki Medical School, General Medical Center Okayama Japan, 4Nara City Hospital Nara Japan, 5Saga University Hospital Saga Japan

Purpose: Metabolic dysfunction-associated steatotic liver disease (MASLD) is recognized to occur not only in obese but also in non-obese individuals. There is no consensus on the long-term prognosis of non-obese MASLD patients. Since mutations in single nucleotide polymorphisms (SNPs) are known to be involved in the progression of MASLD, we investigated the impact of SNPs on the long-term prognosis of non-obese MASLD patients.

Methods: This is a multicenter, retrospective cohort study. Patients diagnosed with MASLD by liver biopsy between November 1, 1997 and October 31, 2020 and examined for SNPs including PNPLA3, TM6SF2, and HSD17B13 were enrolled. Patients were followed until December 31, 2022, for death and clinical events.

Results: Of 1294 MASLD patients, 331 (25.6%) were non-obese. They also included 147 (44.4%) patients with PNPLA3 type GG, which was significantly higher than in the obese group (p=0.04). After a median follow-up of 7.6 years, 17 (5.1%) patients in the non-obese group and 33 (3.4%) in the obese group died, and the Kaplan-Meier method showed no significant difference in survival rates between the two groups.

Conclusion: Non-obese MASLD is more susceptible to SNPs than obese MASLD. Our results suggest that analysis of SNPs, especially PNPLA3, may be able to predict prognosis in non-obese MASLD patients.

AI diagnostic system accurately diagnoses hepatocellular carcinoma in nonalcoholic steatohepatitis

Takeshi Okanoue1, Kanji Yamaguchi2, Toshihide Shima3, Yasuhide Mitsumoto3, Yuya Seko2, Michihisa Moriguchi2, Yoshito Itoh2

1Department of Gastroenterology, Saiseikai Suita Hospital Osaka, Suita Japan, 2Department of Gastroenterology, Kyoto Prefectural University of Medicine Kyoto Japan

Background & Aims: To develop a novel noninvasive test using an artificial intelligence neural network system (named HCC-Scope) that can diagnose early stage hepatocellular carcinoma (HCC) in nonalcoholic steatohepatitis (NASH).

Methods: 175 with histologically proven nonalcoholic fatty liver disease (NAFLD) and 55 NASH-HCC patients were enrolled. Of the 55 HCC patients 27 (49.1%) were very early stage HCC and 6 (10.9%) were early stage HCC. HCC-Scope was conducted using 15 items: age, sex, height, weight, body mass index, aspartate aminotransferase, alanine aminotransferase, gamma-glutamyl transferase, cholesterol, triglyceride, platelet count, diabetes, alpha-fetoprotein (AFP), des-gamma-carboxy prothrombin (DCP), and IgM-free apoptosis inhibitor of macrophage (FAIM). The FMVWG2U47 (Fujitsu Co. Ltd) hardware and the originally developed software were used.

Results: Differential diagnosis between not HCC and HCC using the HCC-Scope revealed 100.0% sensitivity, 100.0% specificity, 100.0% positive predictive value, and 100.0% negative predictive value in a training study with gray-zone analysis, and which was also effective in the analysis in the explorative study. It was also excellent in the validation study (95.0% sensitivity, 100.0% specificity, 100.0% PPV, and 97.1% NPV with gray zone analysis, and it was 95.2%, 100.0%, 100.0% and 97.1% without gray zone analysis. HCC-Scope showed significantly better sensitivity and specificity than AFP, AFP-L3, DCP and even then than GALAD (gender, age, AFP-L3, AFP, DCP) score (its sensitivity: 85.3%, specificity: 85.1%).

Conclusions: The newly developed artificial intelligence neural network system algorithms termed HCC-Scope are easy to use and can
accurately differentially diagnose between NASH without HCC and NASH-HCC including early stage HCC.

Comprehensive Analysis of Specific MicroRNAs Related to Therapeutic Efficacy of Pemafibrate in MASLD
Asahiro Morishita1, Kyoko Oura1, Takuma Kei1, Mai Nakahara1, Tomoko Todokoro1, Koji Fujito1, Joji Tani1, Takashi Himoto2, Tsutomu Masaki1
1Kagawa University Kita-gun Japan, 2Kagawa Prefectural University of Health Sciences Takamatsu Japan

Background: MASLD has become a major social problem in recent years. Pemafibrate binds to PPARs and regulates the expression of its target gene, thereby decreasing plasma triglyceride levels and increasing HDL-cholesterol.

Aim: The aim of this study was to comprehensively analyze the efficacy of pemafibrate in patients with hyperlipidemia complicated with MASLD and the specific microRNAs involved in its therapeutic effect.

Methods: Thirty hyperlipidemia complicated patients with a confirmed diagnosis of NAFLD were treated with pemafibrate, a hyperlipidemic drug, as usual medical treatment. In parallel, clinical data (T-Bil, ALB, AST, ALT, platelets, type IV collagen 7S, M2BPG, Autotaxin, FIB-4 index), efficacy (liver function, changes in the degree of liver fibrosis, etc.), and safety in MAFLD treated with exercise and diet, Fobroscan data and microRNA were comprehensively analyzed.

Results: Comparing clinical data before, one month after, and three months after Pemafibrate administration, significant changes were observed in AST, ALT, and Autotaxin, and correlated with the FAST score. Comprehensive analysis of microRNA expression in serum before and 3 months after treatment showed that they formed different clusters. The number of microRNAs that were significantly up-regulated and down-regulated was 15 and 10 molecules, respectively.

Discussion: Pemafibrate treatment significantly altered microRNAs, consistent with the improvement in clinical data and FAST score. These microRNAs may be involved in the therapeutic effect of Pemafibrate.

Conclusion: Pemafibrate is effective in improving liver function in MASLD patients with hyperlipidemia, and the specific microRNAs involved in the therapeutic effect may help to elucidate the mechanism of this effect.

Study to compare the efficacies of vitamin E and Saroglitazar in non diabetic NAFLD patients
SANJAY KUMAR1, PRANAV RAGHUVANSHI1, NEETU KUMAR2, VINOOD NARKHED2, NAVEEN TMU3, MAYANK PATERIYA1, KSHTIJ KAPIL1, SATISH KAPIL1
1BHOPAL INSTITUTE OF GASTROENTEROLOGY, BHOPAL CORE HOSPITAL, BHOPAL India, 2Chirayu medical college bhopal India, 3LN medical college bhopal india

Introduction: NAFLD (Nonalcoholic fatty liver disease) is a major cause of chronic liver disease globally. The spectrum of NAFLD ranges from simple steatosis to non-alcoholic steatohepatitis which can progress to cirrhosis and hepatocellular carcinoma. There is no study comparing Vitamin E and Saroglitazar in non diabetic NAFLD patients.

Methods: It is a retrospective observational study conducted in Gastrocare hospital over a period of 4 years. The subjects having CAP score 215 or more (E score < 12.5kPa) were labeled as NAFLD. Total subjects included in the study were 306, 158 in Vitamin E group and 148 in Saroglitazar group. Subjects received capsule Vitamin E 400mg twice daily while Saroglitazar 4mg once daily along with standard treatment.

Results: After completion of 6 months treatment, mean baseline values of CAP scores showed statistically significant reduction from (310±26.4 & 312±31.2) to (268±18.6 & 238.8±18.5) in Vitamin E and Saroglitazar group respectively. After treatment mean E score was 7.1 3.1 and 7.2 3.2 respectively in Vitamin E and Saroglitazar groups. Both groups showed statistically Significant improvement in CAP score after therapy (p value <0.001 for Vitamin E group v/s < 0.001 for Saroglitazar group). On intergroup analysis, there was 13.5% improvement in the CAP score in Vitamin E group where as in Saroglitazar group it was 23.7%. It was found to be statistically significant (P value <0.03).

Conclusion: Both Vitamin E and Saroglitazar showed significant improvement in CAP score but Saroglitazar was significantly more effective than Vitamin E.

Molecular MASLD subtype to inform disease progression and therapeutic decision making
Naoto Fujiwara1, 2, Hayato Nakagawa1, Yujin Hoshida2
1Mie University Mie Japan, 2University of Texas Southwestern Medical Center Texas USA

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) has marked molecular and clinical heterogeneity, yet there is no tool to inform disease progression and therapeutic decision making.

Methods: To identify molecular subtypes of MASLD associated with functional status of the liver, we performed an integrative hepatic transcriptome meta-analysis of multi-regional cohorts, including 1,232 mild- to advanced-stage MASLD patients. The MASLD subtypes were characterized according to clinico-histological features, fibrosis progression, HCC development, and estimated therapeutic effects.

Results: We identified and validated three reproducible subtypes across the cohorts, subtypes 1 to 3. Subtype 1 was associated with advanced histological fibrosis compared to the two other subtypes. Despite the indistinguishable clinico-histological features, the likelihood of histological fibrosis progression for subtype 2 was higher compared to subtype 3 (adjusted odds ratio, 1.43; 95% confidence interval [CI], 1.12-1.84). While subtype 3 was HCC-free up to 15 years, incident HCC rates in subtypes 2 and 3 were comparable (adjusted hazard ratio for subtype 1 compared to subtype 2, 0.75; 95% CI, 0.11-5.27). Based on the findings, we named subtypes 1, 2, and 3 as advanced-MASLD (a-MASLD), progressive-MASLD (p-MASLD), and indolent-MASLD (i-MASLD) subtypes, respectively. Transcriptomic analysis suggests that some of the existing and candidate MASLD therapies may yield subtype-specific benefit. Consistent with the transcriptome-based drug response assessment, cenicriviroc, an oral CCR2/5 antagonist, was more effective in reducing histological fibrosis in p- and a-MASLD in the phase 2b CENTAUR trial.

Conclusion: Molecular MASLD subtypes can serve as a tool to inform disease progression and therapeutic decision making.

Abstract Submission No. 101866
Diagnostic Performance of CT/MRI LI-RADS v2018 in Non-Cirrhotic Steatotic Liver Disease

Justin R Tse1, Jennie J Cao1, Andy Shon1, Luke Yoon1

1Stanford University Stanford United States

Background: Our objective was to assess the performance of LI-RADS among patients with non-cirrhotic steatotic liver disease (SLD).

Methods: This IRB-approved, retrospective study included 119 observations from 77 adult patients (36 women, 41 men; median age 64 years) who received liver protocol CT or MRI from 2010-2023. All patients had SLD by histopathology without cirrhosis. Three board-certified abdominal radiologists blinded to final tissue diagnosis and imaging follow-up assessed each observation per LI-RADS and assigned a final category. Inter-reader agreement with weighted kappa was calculated for major features and final category. The positive predictive value, sensitivity, specificity, and accuracy in identifying hepatocellular carcinoma (HCC) and overall malignancy was calculated.

Results: 75 observations (63%) were benign and 44 (37%) were malignant. Positive predictive value for HCC was 0-0% for LR-1, 0-0% for LR-2, 0-7% for LR-3, 11-20% for LR-4, 75-88% for LR-5, 0-8% for LR-M, and 50-75% for LR-TIV. For overall malignancy, positive predictive value was 0-0% for LR-1, 0-11% for LR-2, 3-9% for LR-3, 16-31% for LR-4, 78-88% for LR-5, 65-100% for LR-M, and 100-100% for LR-TIV. For LR-5 in identifying HCC, sensitivity was 79-83%, specificity was 91-97%, and accuracy was 89-92%. For composite categories of LR-5, LR-M, or LR-TIV in identifying overall malignancy, sensitivity was 86-89%, specificity was 85-96%, and accuracy was 86-93%. Most common false positives for LR-5 were hepatocellular adenomas. Inter-reader agreement for final category was 0.766.

Conclusion: LI-RADS 5 still most commonly represents HCC, but its specificity is slightly lowered due to misclassification of hepatocellular adenomas.

Causespecific mortality in Japanese patients with biopsy-confirmed nonalcoholic fatty liver diseases

Kyoko Sakai1,2, Toshihide Shima3, Keiichiro Okuda4, Hirohisa Oya5, Takayuki Katayama6, Yasuhide Mitsumoto7, Masayuki Mizuno8, Takeshi Okanoue3

1Department of Laboratory Medicine, Saiseikai Suita Hospital Suita Japan, 2Health Informatics, Kyoto University School of Public Health Kyoto Japan, 3Department of Gastroenterology and Hepatology, Saiseikai Suita Hospital Suita Japan, 4Kento Health management Center Suita Japan

Objectives: The main cause of death in NAFLD patients is considered to be CVD in the West. We examined mortality and causes of death in Japanese NAFLD patients.

Methods: Histologically diagnosed NAFLD patients at Saiseikai Suita Hospital, between 2004 and 2023 were included. As a prospective cohort study, mortality using the Kaplan-Meier method and causes of death were verified, compared for NAFL versus NASH and mild versus advanced fibrosis.

Results: The study included 1085 subjects (a mean age 57.2, a mean observation period 6.65 years). During the period, 76 patients died, with a mortality of 72 /747 in the NASH, higher than in the NAFL 4 /338 (p<0.0001). After adjustment for age and sex, NASH (HR 7.35), men (HR 2.05) and older age (HR 1.09) were risks of death.

Mortality was higher (p<0.0001) in the advanced fibrosis group (41/218) than in the mild (35/867). After adjustment, advanced fibrosis (HR 3.64), men (HR 1.93) and older age (HR 1.08) were risks of death. Causes of death in NAFLD patients included 17 HCC, 16 cirrhosis, 18 extrahepatic malignancies, 3 CVD, 8 other and 13 unknown causes. Mortality from liver-related diseases was higher in the NASH/advanced fibrosis than in the NAFL/mild fibrosis, while mortality from extrahepatic malignancies did not differ.

Conclusion: NASH and advanced fibrosis were independent risks of death. The main causes of death in Japanese NAFLD outpatients were liver-related diseases or extrahepatic malignancies, with less CVD, which may differ from those in the West.

Unveiling NAFLD: The Interplay of SCFA, Elastography, and CAP

Chynthia Olivia Maurine Jasirwan1, Desi Astari2, C. Rinaldi A Lesmana3, Marcellus Simadibrata3

1Hepatobiliary Division, Department of Internal Medicine, Cipto Mangunkusumo Hospital, Faculty of Medicine, Universitas Indonesia Jakarta Indonesia, 2Department of Internal Medicine, Faculty of Medicine, Universitas Indonesia, Cipto Mangunkusumo Hospital Jakarta Indonesia, 3Gastroenterology Division, Department of Internal Medicine, Cipto Mangunkusumo Hospital, Faculty of Medicine, Universitas Indonesia Jakarta Indonesia

Background: Non-alcoholic Fatty Liver Disease (NAFLD), a growing global health concern, is believed to be influenced by multiple factors, including gut microbiota. A key metabolite of gut microbiota, Short Chain Fatty Acid (SCFA), is hypothesized to play a significant role in NAFLD progression.

Objective: This study aims to explore the relationship between SCFA levels and the severity of fibrosis and steatosis in NAFLD, utilizing transient elastography and controlled attenuation parameter (CAP) as assessment tools.

Method: A cross-sectional analysis was conducted on 38 NAFLD patients at Cipto Mangunkusumo Hospital from January to August 2023. The study involved comprehensive patient assessments, including anamnesis, physical examination, laboratory tests, CAP-TE (Transient Elastography), and SCFA analysis via GC-MS (Gas Chromatography-Mass Spectrometry).

Results: Notably, propionate levels were significantly higher in patients with significant fibrosis than in those with less severe fibrosis (p=0.019 for absolute propionate; p=0.035 for propionate level). However, no significant correlation was found between SCFA levels and CAP or transient elastography values (p>0.05).

Conclusion: This study highlights a significant increase in propionate levels in NAFLD patients with pronounced fibrosis, suggesting a potential link between gut metabolites and liver fibrosis. However, SCFA levels did not correlate with CAP and transient elastography values, indicating the complexity of NAFLD pathogenesis.

Keywords: Short Chain Fatty Acid, NAFLD, Transient Elastography, Controlled Attenuation Parameter

Semaglutide for Metabolic-Associated Fatty Liver Disease
Ma. Felina Rosanna Siray1, Pamela Bianca Yap1, Maxine Andrea Garcia1, Marie Antoinette Lontok1
1NIBMG Kolkata India

Background: NAFLD is a chronic liver disorder linked to metabolic syndrome and inflammation. Ferroptosis is a cell death process that depends on iron and lipid oxidation. How ferroptosis affects NAFLD and liver fibrosis is unclear. We used public transcriptomic data to find ferroptosis genes and pathways in NAFLD.

Methodology: We analysed microarray gene expression and clinical data from a cohort of 40 NAFLD human liver samples and 18 healthy controls. We performed differential expression analysis to identify ferroptosis-related genes and putative pathways that may be associated with NAFLD. We harnessed machine-learning approaches, like SVM-RFE and LASSO to identify genes associated with a fibrotic phenotype. We evaluated the prediction accuracy of these genes as biomarkers of NASH using multivariable regression and correlation analysis.

Results: We identified IL17, TNF signalling, JAK-STAT signalling pathways were found to be related to NAFLD progression with FADS2, ZFP36, HNF4A being upregulated and SOCS1, JUN, IL6, SLCA2A3, ATF3, MIOX, PTGS2, CDKN1A being down-regulated. Our machine learning models identified novel genes like SOCS1, HNF4A, MIOX as potential biomarkers with ROC values of 0.92, 0.64 and 0.74.

Conclusion: We explored the role of ferroptosis pathway in NAFLD progression. We found that SOCS1 can modulate HSC activation and fibrosis. We also found that HNF4A can regulate the expression of genes that maintain the epithelial characteristics of hepatocytes and HSCs. We discovered some new genes that may be useful as biomarkers for early detection of NASH.

Semaglutide for Metabolic-Associated Fatty Liver Disease
A Meta Analysis and Systematic Review
Ma. Felina Rosanna Siray1, Pamela Bianca Yap1, Maxine Andrea Garcia1, Marie Antoinette Lontok1
1St. Luke's Medical Center - Global City Taguig Philippines

Background: Semaglutide is a once-weekly glucagon-like peptide-1 receptor agonist with a smaller molecular weight that is approved for the treatment of type 2 diabetes mellitus and obesity. It is associated with dose dependent reduction in HbA1c and body weight among diabetic patients. However, its potential role in the treatment of non-alcoholic steatohepatitis remains unclear. The objective of this study is to determine the effectiveness of semaglutide in decreasing steatosis and fibrosis among patients with metabolic associated fatty liver disease.

Methods: Eligible studies were identified by a systematic literature search of Pubmed, Cochrane, Google scholar databases until September 2023. Randomized control trials were included and the quality of the studies was assessed using the Cochrane handbook. Statistical analyses were conducted using RevMan 5.4 software.

Results: A total of 458 patients from three randomised control trials were included. Histologically, semaglutide increased the likelihood of resolution of steatohepatitis (OR: 3.18, CI: 1.70, 5.95; P < 0.001). Radiologically, semaglutide caused a reduction in liver stiffness as measured by magnetic resonance elastography and fibroscan (SMD: -0.45, CI: -0.84, -0.09; P = 0.02). It also caused a reduction in the degree of steatosis measured by MRI proton density fat fraction (MD: -4.96%, CI: -9.92, 0.01; P = 0.05).

Conclusion: Semaglutide is effective for the histologic resolution of steatohepatitis and the radiologic improvement of both steatosis and fibrosis.

Abstract Submission No. 102055

Pilot randomized controlled trial of effects of dapagliflozin and vitamin E on MASLD with type 2 DM
Kazuyoshi Kon1, Hiro Fukada1, Akira Uchiyama1, Shunhei Yamashina1, Kyoko Fukuhara1, Kenichi Ikejima1
1Juntendo University School of Medicine Tokyo Japan

Aim: We investigated the effects of dapagliflozin and vitamin E on metabolic dysfunction-associated steatotic live disease (MASLD) with type 2 diabetes by randomized, open-label, controlled study.

Methods: Total 24 patients with an HbA1c ≥ 6.5%, hepatic steatosis on ultrasonography, and ethanol consumption of < 30 g/day for men and < 20 g/day for women were randomly assigned to treatment with dapagliflozin 5 mg (DAPA group, n=13) and tocopherol 150 mg (VE group, n=11), and the clinical course was monitored during the 24-week-treatment period (jRCT1031180386).

Results: Three patients in DAPA group complained of frequent urination or dry mouth, and 1 of them discontinued treatment due to frequent urination. There was no significant difference between clinical courses of the two groups by repeated measures analysis of variance. Comparing before and after 24 weeks of the start of treatment in each group, both AST and ALT values significantly decreased in DAPA group whereas only AST levels significantly decreased in VE group. In addition, BMI, body fat percentage and HbA1c levels decreased significantly in DAPA group. No significant decrease in fibrosis markers or liver stiffness was observed before and after treatment in either group.

Conclusion: Tocopherol reduced only serum AST levels, whereas dapagliflozin significantly lowered both serum AST and ALT levels in MASLD with type 2 diabetes; however, there was no significant difference between the two groups in a group comparison. These findings revealed the benefits and risks of treating MASLD with type 2 diabetes using SGLT2 inhibitor or vitamin E.

Meta-analysis of Luseogliflozin on Hepatic Steatosis/Fibrosis Indexes in Diabetic Patients in Japan
Takumi Kawaguchi1, 2, Kenta Murotani2, 3, Hiromitsu Kajiyama4, Hitoshi Obara1, 3, Hironori Yamaguchi5, Yuku Toyofukui6, Fumi Kaneko7, Saeko Uchida8
1Division of Gastroenterology, Department of Medicine, Kurume University School of Medicine Kurume Japan, 2Clinical Research Center, Kurume University Hospital Kurume Japan, 3Biostatistics Center, Kurume University Kurume Japan, 4Taisho Pharmaceutical Co., Ltd. Tokyo Japan

Backgrounds: Luseogliflozin, a sodium-glucose cotransporter 2 (SGLT2) inhibitor, is known to decrease serum ALT levels in patients with diabetes mellitus. We aimed to investigate the effects of luseogliflozin on hepatic steatosis/fibrosis indexes and BMI in Japanese patients with diabetes mellitus by a meta-analysis.

Methods: In this pooled meta-analysis, we included 5 phase III clinical trials conducted in Japan. The primary outcomes were fatty liver index (FLI) and aspartate aminotransferase to platelet ratio index (APRI) after 24 weeks. The secondary outcome was BMI after 24 weeks. Statistical analysis was performed using propensity scoring analysis by the inverse probability of treatment weighting (IPTW) method.
Ehocrine function and obesity may then lead to non-alcoholic fatty liver disease (NAFLD), and progression to cirrhosis or even hepatocellular carcinoma.

In this study, we aimed to investigate the relationship between obesity and NAFLD, and how this relationship changes with increasing BMI.

**Methods:**
We performed a cross-sectional study of 1,000 participants who were consecutively recruited from a local hospital. All participants underwent a detailed medical history, physical examination, and laboratory tests, including liver function tests, lipid profile, and anthropometric measurements.

**Results:**
The prevalence of NAFLD was significantly higher in participants with a BMI of 25 or more compared to those with a BMI less than 25. Furthermore, the prevalence of NAFLD increased with increasing BMI, from 7.2% in participants with a BMI of 25 to 30, to 20.7% in those with a BMI of 30 or more.

**Conclusion:**
Our study confirms the strong association between obesity and NAFLD, highlighting the importance of weight management and lifestyle interventions to prevent and manage NAFLD.

The Effects of GLP-1 Receptor Agonists in Histological Improvement of NASH: A Meta-analysis of RCT

STEATOHEPATITIS-A RANDOMIZED CONTROL TRIAL

MEHREEN SIYAL1, ZAIGHAM ABBAS1, MUHAMMAD ALI QADEER1, ALINA SAEED1, ABEER ALTAF1

1Dr. Ziauddin Hospital, Clifton Campus, Karachi Pakistan

Background: The management of non-alcoholic steatohepatitis (NASH) is an unmet clinical need. Misoprostol, a structural analogue of naturally occurring prostaglandin E1 (PGE1), has been reported to decrease pro-inflammatory cytokine production and may have a potential role to treat NASH. We aimed to evaluate the efficacy and safety of misoprostol in treating patients with NASH.

Methods: In this phase 2, double-blind, randomized, placebo-controlled trial, patients with NASH were randomly assigned in a 1:1 ratio to receive 200 mcg of misoprostol or placebo thrice daily for 2 months. The primary endpoint was an improvement in liver function tests, interleukin-6 (IL-6), and endotoxin levels. The secondary endpoint was improvement in insulin resistance, dyslipidemia, hepatic fibrosis, and hepatic steatosis.

Results: A total of 50 patients underwent randomization, of whom forty-four (88%) were males. The age range was 25-64 years (mean38.1±SEM1.4). 19 (38%) patients had concomitant type 2 diabetes mellitus. 32 (64%) patients were either overweight or obese. At the end of 2 months treatment, a reduction in total leucocyte count (TLC) (p=0.005), alanine aminotransferase (ALT) (p<0.001), aspartate aminotransferase (AST) (p=0.002), and controlled attenuation parameter (CAP) (p=0.003) was observed in the misoprostol group, whereas placebo ensued a decline in ALT (p<0.001), AST (p=0.018), gamma glutamyl transferase (GGT) (p=0.003), CAP (p=0.010) and triglycerides (p=0.048). There was no diminution in insulin resistance, hepatic fibrosis, and dyslipidemia in both groups. However, misoprostol resulted in a significant reduction in CAP as compared with the placebo group (p=0.039). Moreover, in the misoprostol group pre and post treatment IL-6 and endotoxin levels remained stable, while in the placebo group, an increase in the IL-6 levels was noted (p=0.049). In the misoprostol group six (12%) patients had at least one adverse event in the misoprostol group, as did five (10%) in the placebo group. The most common adverse event in the misoprostol group was diarrhoea. No life-threatening events or treatment-related deaths occurred in each group.

Conclusions: Improvement in biochemical profile was seen both in misoprostol and placebo groups without any statistically significant difference. However, there was more improvement in steatosis, as depicted by CAP, in the misoprostol group and worsening of IL-6 levels in the placebo group.

Association of sex and baseline ALT levels with response to pioglitazone for SLD patients

Ming-Ling Chang1, 2

1Department of Hepatology and Gastroenterology, Chang Gung Memorial Hospital, Linkou, Taiwan Taoyuan Taiwan; 2Department of medicine, College of Medicine, Chang Gung University Taoyuan Taiwan

Background/Aim: The response rate and factors for pioglitazone to improve liver biochemistry of steatoatrophic liver diseases (SLD) patients remained elusive in Taiwan.

Methods: A 3-year prospective cohort study of 126 Taiwanese SLD patients treated with pioglitazone (15-30 mg/day) was conducted. The genetics including phospholipase domain-containing protein 3 (PLD3), rs738409, methylenetetrahydrofolate reductase (MTHFR) rs1801133 and aldehyde dehydrogenase 2 (ALDH2)-rs671 were assessed.

Results: Of 126, 78 (61.9%) were males, with a mean and median ages of 54.3 and 56.5 years, respectively; 105 (83.3%) were pioglitazone responders (decreased alanine aminotransferase (ALT) levels at 6 months after treatment). Compared with non-responders, the responders were more frequently female, had higher baseline ALT but lower uric acid levels and lower ALDH2-rs671 GG genotype rates (38.6% vs. 66.6%, p=0.027). Sex [female sex: odds ratio (OR): 4.514, p=0.023] and baseline ALT levels (OR:1:015, p=0.046) were
associated with pioglitazone response. The cut-off level for baseline ALT to predict pioglitazone response is 82 U/L. Among responders, liver biochemistry and HOMA-IR were improved from 6 months to 24 months after treatment. Total cholesterol levels reduced in the first 6 months, while HDL-C increment, triglycerides and fibrosis-4 index reductions were noted only at 24 months after treatment.

**Conclusions:** For liver biochemistry, over 80% of SLD Taiwanese had pioglitazone response, which was positively associated with female sex and baseline ALT levels. Insulin resistance improved as early as 6 months after treatment, while liver fibrosis improvement was not evident until 24 months after treatment. The link between pioglitazone response and ALDH2 genotype demands further investigation.

**Background & Aims:** Lifestyle intervention is the mainstay of therapy for metabolic-associated steatohepatitis (MASH), and liver fibrosis is a key consequence of MASH that predicts adverse clinical outcomes. The placebo response plays a pivotal role in the MASH clinical trials. Second harmonic generation/two-photon excitation fluorescence (SHG/TPEF) microscopy with artificial intelligence analyses provides an automated quantitative assessment of fibrosis on a continuous scale, called qFibrosis. We used this approach to gain insight into lifestyle intervention-induced fibrosis changes in MASH.

**Methods:** We examined unstained sections from paired liver biopsies (baseline and end-of-intervention) from MASH patients who had received either routine lifestyle intervention (RLI) (n=35) or strengthened lifestyle intervention (SLI) (n=17). We quantified liver fibrosis with qFibrosis in the portal tract, periporal, transitional, pericentral, and central vein regions.

**Results:** 20% (7/35) and 65% (11/17) of patients had fibrosis regression in the RLI and SLI groups, respectively. Liver fibrosis tended toward no change or regression after each lifestyle intervention, and this phenomenon was more prominent in the SLI group. SLI-induced fibrosis regression was mainly concentrated in the periporal region.

**Conclusions:** Using digital pathology, we could detect more pronounced fibrosis regression in the periporal region, with SLI. The patients with RLI were regarded as placebo patients with awareness of MASH conditions. With fibrosis regression in the periporal region, we could potentially differentiate RLI and SLI patients in the placebo group in the MASH clinical trial. Digital pathology provides new insight into lifestyle-induced fibrosis regression and placebo response, which is not captured by conventional histological staging.

**Risk factors for extrahepatic cancer in people with non-alcoholic fatty liver disease**

Patricia Valery1, 4, Richard Skoien2, 7, James O’Beirne3, Gunter Hartel1, Louisa Gordon1, Babak Sarraf1, 6, Barbara Leggett9, Elizabeth E Powell1, 5, 6

1QIMR Berghofer Medical Research Institute Herston Australia, 2Royal Brisbane and Women’s Hospital Brisbane Australia, 3Sunshine Coast University Hospital Sunshine Coast Australia, 4Faculty of Medicine, The University of Queensland Brisbane Australia, 5Centre for Liver Disease Research, Translational Research Institute, Faculty of Medicine, The University of Queensland Brisbane Australia, 6Department of Gastroenterology and Hepatology, Princess Alexandra Hospital Brisbane Australia

**Background:** Although cancer is the second leading cause of death in people with non-alcoholic fatty liver disease (NAFLD), the magnitude of risk and relationship with disease severity and metabolic comorbidity remains unclear. We compared incidence of cancers in people hospitalised with NAFLD or non-alcoholic steatohepatitis (NASH) during 2007-2019 in Queensland, Australia, and investigated the association between cirrhosis, type 2 diabetes (T2D) and cancer risk.

**Methods:** In this retrospective state-wide data-linkage cohort study, we identified all cancers after the first hospitalisation with NAFLD/NASH to December-2019, estimated age-standardized incidence (ASIs) of cancers, compared that to the ASI in the Queensland population (incidence rate-ratios (IRR)), and examined the association between cirrhosis, type 2 diabetes (T2D) and cancer risk.

**Results:** 11,483 patients age ≥20 years with NAFLD/NASH followed for a median of 3.8 years (interquartile range 1.5-7.4 years; 54,204 person-years) were diagnosed with 1,104 primary cancers. The ASI of any cancer in NAFLD/NASH patients (1,460/100,000 person-years, 95%CI 1,368-1,557) was double the ASI in the Queensland population (incidence rate-ratios (IRR)), and examined the association between cirrhosis, T2D and cancer risk (Cox regression).

**Results:** 11,483 patients age ≥20 years with NAFLD/NASH followed for a median of 3.8 years (interquartile range 1.5-7.4 years; 54,204 person-years) were diagnosed with 1,104 primary cancers. The ASI of any cancer in NAFLD/NASH patients (1,460/100,000 person-years, 95%CI 1,368-1,557) was double the ASI in the Queensland population for men (IRR=1.94, 95%CI 1.75-2.16)* and women (IRR=1.99, 95%CI 1.78-2.22)*. The ASI of extrahepatic cancers was 1,326/100,000 person-years (95%CI 1.238-1,419), and was 1.5-fold higher (95%CI 1.13-2.00)* in patients with cirrhosis vs not, but did not vary by T2D status (IRR=1.08, 95%CI 0.84-1.38). In multivariable analysis, age, T2D and cirrhosis were associated with increased extrahepatic cancer risk (Table).

**Conclusions:** NAFLD is associated with a significantly increased risk of extrahepatic cancer. Demonstrating a higher risk in people with cirrhosis, T2D, men, and age ≥40 years provides an opportunity for targeted vigilance.

Antifibrotic effect of Polylene phosphatidylcholine in chinese MAFLD patients: a real-world study.

Vi Pan1, 2, Feng Xue1, 2, Shanshan Wang3, Shuangqing Gao3, Lai Wei8

1Beijing Tsinghua Changgung Hospital, Tsinghua University, China Beijing China, 2School of Clinical Medicine, Tsinghua University, China Beijing China, 3Beijing North Medical & Health Economic Research Center Beijing China

Background: Polylene phosphatidylcholine is considered one of the most promising therapeutic agents for the treatment of steatosis because of its antioxidant, anti-inflammatory, and anti-fibrotic actions by liver cell regeneration. We aimed to conduct an observational study based on retrospective real-world data to analyze the antifibrotic effect of Polylene phosphatidylcholine (Essentiale® Capsule, Ess) in MAFLD patients.

Methods: This is a multicenter, retrospective study. Patients with MAFLD (aged≥18) were identified from the tertiary public hospital electronic database between January 1st, 2020 and December 31st, 2022 following APASL 2020 guideline. Propensity score matching (PSM) was used to match Ess monotherapy group and control (non-hepato-protective-treated) group at a 1:1 ratio. The primary endpoint was the change of fibrosis-4 index (FIB-4) after 24 weeks treatment with Ess.

Results: The median age of enrolled 82,908 MAFLD patients from 11 hospitals was 53 (IQR, 43-63) years old and 64.3% were male. The median FIB-4 was 1.22 (IQR, 0.83-1.85). Among the FIB-4-based fibrosis risk stratification, 33.4% were at intermediate-risk (1.3-2.67), and 12.3% were at high-risk (>2.67). Of the 291 MAFLD patients treated with Ess only for 24 weeks, 42 patients have FIB-4 data. After PSM analysis matching for age, sex, T2DM, CVD, hypertension, and hyperlipidemia, the FIB-4 index adjusted for covariates was significantly reduced in the Ess-treated group than control group by using ANCOVA (-0.12±0.62 for Ess vs. 0.11±0.50 for control, P = 0.034).

Conclusions: Our study found that Ess treatment for 24 weeks can significantly reduce the FIB-4 index in MAFLD patients. Funding by Sanofi.

10Key Laboratory of Diagnosis and Treatment for The Development of Chronic Liver Disease in Zhejiang Province, Wenzhou, China Wenzhou China

Background: A decline in skeletal muscle strength is closely associated with metabolic diseases, but whether skeletal muscle strength declines with chronic kidney disease (CKD) in people with metabolic dysfunction-associated fatty liver disease (MAFLD) is uncertain. This study investigated the association between skeletal muscle strength and metabolic dysfunction-associated fatty liver disease with chronic kidney disease (MLKD).

Method: We performed cross-sectional investigations within a hospital-based Chinese liver biopsy cohort (the PERSONS cohort; n=460) and a United States population-based cohort (NHANES 2011-2014 cohort; n=1,414), respectively. A handgrip dynamometer measured handgrip strength as a proxy for overall skeletal muscle strength. Subjects were stratified according to the absence [non-CKD (stage 0)] or presence of CKD (stages 1-5).

Results: In the PERSONS cohort, the CKD group had a significantly lower handgrip strength than the non-CKD group (27.02±9.27 vs. 33.59±11.90 kg, p<0.05). In a generalized additive logistic regression model, there was an inverse association between handgrip strength and the risk of abnormal albuminuria or CKD and higher handgrip strength was associated with lower odds of albuminuria or CKD (OR: 0.95, 95%CI: 0.92-0.99, p=0.018; OR: 0.95, 95%CI: 0.91-0.99, p=0.009) after adjustment for potential confounders. The highest handgrip strength tertile was associated with the lowest risk of abnormal albuminuria or CKD (compared with the lowest or the middle tertile). The results were validated using the NHANES 2011-2014 cohort. Combining handgrip strength, age, sex, BMI, hypertension and diabetes status to discriminate between MLKD and non-MLKD groups had an AUROC of 0.74 (95% CI: 0.67-0.81) in the PERSONS cohort and 0.72 (95% CI: 0.68-0.75) in the NHANES 2011-2014 cohort.

Conclusion: Lower handgrip/muscle strength is closely associated with a higher risk of abnormal albuminuria or CKD in people with MAFLD.
Salivary amylase: Is a glucose polymer cleavage enzyme produced mainly by pancreas, salivary glands and is expressed in many body organs as liver, brain, kidneys, intestine, lacrymal glands. Recent several researches proved positive correlations between low copy numbers of amylase and type 1. type 11 diabetes obesity, metabolic syndrome and NAFLD. Other studies show inverse correlation of amylase copy numbers with total visceral fat volume. Also positive correlation with HDL cholesterol, serum adiponectin. Subjects with high copy number of amylase have gut microbiota able of degradation of resistant starch so produce higher level of short chain fatty acids. Upon these back-ground of data we suggest that it may be effective in treating and/or prophylactic NAFLD in experimental animals.

Ectopic liver fat is associated with diabetes and adverse cardiac remodeling

Vivian Lee1, Yiying Han2, Desiree-Faye Toh1, Jennifer A Bryant2, Redha Boubertakh0, Thu-Thao Le1, 3, Calvin WL Chin8

1National Heart Centre Singapore Singapore Singapore, 2Department of Cardiology, National Heart Centre Singapore Singapore Singapore, 3Cardiovascular Academic Clinical Program (ACP), Duke-NUS Medical School Singapore Singapore

Background: We aim to characterize fat composition in the liver and abdominal depots by magnetic resonance imaging (MRI), in relation to diabetes and cardiac remodeling.

Methods: A cohort of 149 adults (57±13 years, 65% males, 38% type 2 diabetes) from the National Heart Centre Singapore Biobank underwent multiparametric MRI for quantification of liver proton-density-fat-fraction (PDFF) and abdominal subcutaneous and visceral adipose tissue (SAT, VAT), analyzed by trained operators blinded to clinical data (Perspectum, Oxford, UK). PDFF >5.6% was considered as abnormal liver fat accumulation. Adverse features of cardiac functions and remodeling were evaluated by cardiac MRI. Multivariate linear and logistic regressions were performed to assess independent associations of PDFF as a continuous and categorical variable, respectively, with other parameters. Analyses were adjusted for potential confounders including age, sex, systolic blood pressure, BMI, diabetes and hyperlipidemia.

Results: Increased PDFF was associated with VAT (β=0.49, P<0.001) but not with SAT. Diabetic individuals had significantly higher PDFF [9.6 (5.2-17.7) versus 5.5 (2.8-8.9)], P<0.001] and diabetes status was independently associated with elevated PDFF (β=0.24, P=0.007). Stratifying by PDFF 5.6% threshold, those with excessive liver fat were associated with diabetes (OR=3.82, 95% CI=1.54-9.46, P=0.004), reduced stroke volume (β=0.18, P=0.031) and increased global myocardial wall stress denoted by a lower remodeling index (β=0.19, P=0.012). Findings remained consistent with PDFF as a continuous variable, whereby increased PDFF was associated with reduced stroke volume (β=0.27, P=0.002) and worse remodeling index (β=0.15, P=0.049).

Conclusion: Ectopic liver fat accumulation was associated with visceral adiposity, diabetes and adverse cardiac remodeling.

Abstract Submission No. 100500
O-0374
A phase I DDI study to evaluate the effect of ASC42 on the pharmacokinetics of atorvastatin

Jinzi J. Wu1, Handan He1

1Gannex Pharma Co., Ltd Shanghai China

Background and Aims: Farnesoid X receptor (FXR) agonist, ASC42, is a potential drug candidate for nonalcoholic fatty liver disease (NAFLD) and primary biliary cholangitis (PBC). ASC42 is an inhibitor of organic anion transporter polypeptide 1B1 and 1B3 (OATP1 B1/OATP1B3). This study (NCT05464628) aimed to evaluate the effects of ASC42 on the pharmacokinetics (PK) of atorvastatin and its metabolite (2-hydroxy-atorvastatin), and safety of atorvastatin in the presence of ASC42 in healthy subjects.

Method: Twelve healthy subjects were dosed orally with a single dose of 20mg atorvastatin on Day 1 followed by a daily dose of 15mg ASC42 on Day 6 through Day 15. On Day 11, subjects received both 15mg ASC42 and 20mg atorvastatin. Samples for PK were collected on Days 1 and 11.

Results: Atorvastatin Cmax was 15% lower, while AUCinf, AUC0-24, and AUClast were similar when atorvastatin was co-administered with ASC42. There was little/no change of 2-hydroxy-atorvastatin PK parameters when atorvastatin was co-administered with ASC42. As for ASC42, following multiple dose administration of ASC42 in combination with a single dose of atorvastatin, the inter-subject variability for Cmax, and AUCs were moderate, ranging from 38% to 47%. Six adverse events (AEs) were reported in 5 subjects (41.7%), and all were mild (grade 1) in severity and only 1 AE (8.3%) was considered probably related to study drug.

Conclusion: ASC42 has no effect on the overall exposure of atorvastatin or its metabolite, 2-hydroxy-atorvastatin, and co-administration of atorvastatin 20mg and ASC42 15mg was safe and well tolerated in healthy subjects.

Abstract Submission No. 100547

Non-Alcoholic Fatty Liver Disease (NAFLD) burden among Filipino People Living with HIV (PLHIV)

GILLIE ANNE D. DOMINGO1, VERONICA S. BUGNA1, NATASHA A. MAPA1, MA. TARCELA S. GLER1, MADALINEE ETERNITY D. LABIO2

1Makati Medical Center Makati City Philippines

Background: Non-Alcoholic Fatty Liver Disease (NAFLD) is a significant concern for people living with HIV (PLHIV) due to its impact on non-HIV-related mortality.

Methods: A total of 35 Filipino male patients with HIV were screened which included 27 patients divided into two groups: 15 with NAFLD and 12 without, resulting in a 55% NAFLD prevalence.

Results: The average age of patients was 38 years, with an HIV duration of 7 years and a mean CD4 count of approximately 600 cells/mm3. Antiretroviral regimens included Lamivudine + Tenofovir with Dolutegravir (44%), Efavirenz (52%), and one patient on Lamivudine + Zidovudine + Efavirenz (4%). Both groups experienced dyslipidemia, with 73% of NAFLD patients and 67% of those without NAFLD affected. Among NAFLD patients, 53% were overweight, often associated with Type 2 Diabetes and Hypertension (26%). In contrast, 83% of those without NAFLD had a normal BMI and a higher rate of opportunistic co-infections (50%). Liver-related measurements, including mean transaminase levels (AST: 77, ALT: 144), liver stiffness (8.3 kPa), and CAP scores (330 dB/m), were higher in the NAFLD group compared to those without NAFLD. Although mean FIB4 scores indicated mild fibrosis in all patients, mean APRI scores revealed evidence of fibrosis (0.76) in the
NAFLD group, while those without NAFLD showed an absence of fibrosis (0.46).

**Conclusion:** Risk factors of metabolic syndrome (overweight, hypertension, diabetes) are strongly linked to NAFLD in PLHIV. There is no significant relationship between ARV regimen, CD4 count, HIV duration and presence of opportunistic co-infections in development of NAFLD.

---

**Long-term impact of metabolic dysfunction-associated fatty liver disease on cardiovascular diseases**

**Szu-Ching Yin, Tzu-I Chen, Yi-Ting Chen, Xia-Rong Liu, Yun-Zheng Gao, Mei-Hsuan Lee**

1Institute of Clinical Medicine, National Yang Ming Chiao Tung University Taipei Taiwan

**Background & Aims:** The prospective study aimed to investigate the potential influence of metabolic dysfunction-associated steatotic liver disease (MASLD) on the associated risk of cardiovascular disease (CVD).

**Methods:** We enrolled 329,528 adults aged ≥30 years who participated in a health screening program from 1997 through 2013. MASLD was defined by abdominal ultrasound-observed hepatic steatosis, limited alcohol consumption (<20 g/d for men and <10 g/d for women), and cardiometabolic risk factors. Participants were categorized into non-steatotic liver disease and the MASLD groups. We linked data to the Taiwan National Health Insurance Database (1997-2020) to identify CVD incidence and subtypes using ICD codes. Cox’s proportional hazards models were used to estimate hazard ratios (HRs) and 95% confidence intervals (CIs) for MASLD’s impact on each CVD subtype.

**Results:** Among all participants, 106,926 were classified as having MASLD, while 222,602 were classified as having non-steatotic liver disease, resulting in a MASLD prevalence of 32.4%. Individuals with MASLD were more likely to be older, male, having a higher body mass index, diabetes, and more cardiometabolic risk factors (p<0.05). There were a total of 125,053 CVD cases, including 6,033 myocardial infarction, 10,955 atrial fibrillation, and 21,585 heart failure cases. Using the non-SLD as a reference, the multivariate-adjusted HRs (95% CIs) for MASLD were: 1.21 (1.19-1.23) for all CVD, 1.80 (1.71-1.90) for myocardial infarction, 1.21 (1.08-1.17) for atrial fibrillation, and 1.23 (1.24-1.31) for heart failure.

**Conclusion:** MASLD was linked to an increased risk of CVD and its subtypes, highlighting the need for behavior modifications and risk consultations.

**Patients with Diabetes Mellitus and Liver Diseases in Azerbaijan: Epidemiological Studies**

**Gulnara Aghayeva, Saltanat Maharramzade**

1Baku Branch of Sechenov Medical University Baku Azerbaijan,
2Baku Health Center Baku Azerbaijan

**Introduction:** Diabetes mellitus - a metabolic disorder, which is expected to affect 300-400 million worldwide by 2030. Multiple studies with subsequent meta-analyses from Europe, Asia, and North America support the idea that DM and insulin resistance are independent risk factors for liver diseases and HCC. According to official data, there are about 300,000 patients with type 2 diabetes mellitus in Azerbaijan. There are not any epidemiological studies about Diabetes Mellitus and its relationship with liver diseases.

**Methods:** We have collected data for 3110 patients with Diabetes Mellitus admitted between January 2008 and June 2023 to Baku Health Center.

**Results:** There were 2425 patients with MAFLD/NAFLD (78%), 544 patients (17.5%) with liver cirrhosis and 139 patients (4.5%) with HCC. Among patients with MAFLD/NAFLD males accounted for 43.5%- (mean age- 52 y), and 56.5%-females (mean age- 57 y). Among patients with liver cirrhosis 50% were males (mean age - 60 y), females -50% (mean age-69 y). Among patients with HCC -62% were males (mean age-64 y), and 38%-females (mean age-67y).

**Conclusion:** Liver involvement in type 2 diabetes has been found in a large number of cases in the form of non-alcoholic fatty liver disease associated fatty liver disease (NAFLD/MAFLD), which can range from simple steatosis to non-alcoholic steatohepatitis (NASH), cirrhosis and HCC. The mean age of patients increases in correlation with the severity of liver pathology, which confirms the importance of the duration of diabetes mellitus as a pathogenic factor. Follow-up examination of the liver are recommended in patients with diabetes mellitus.
The Impact of Fatty Liver Index on HCC among non-viral hepatitis subjects in an HBV endemic region

Iqbal Taufiqurrahman1,2, Irsan Hasan2
1Pondok Indah Hospital, Jakarta, Indonesia Jakarta, Indonesia, 2Hepatobiliary Division, Department of Internal Medicine, Faculty of Medicine Universitas Indonesia - Cipto Mangunkusumo Hospital Jakarta Indonesia

The prevalence of metabolic-associated fatty liver disease (MAFLD), which was previously known as non-alcoholic fatty liver disease (NAFLD) in Asia was increased to 29.62%. The considered causes are the socio-economic changes and the overnutrition condition in Asia. Serum vitamin D level is considered to increase the risk of fatty liver. However, the study that reports the efficacy of vitamin D supplementation for patients with MAFLD or NAFLD is limited. This systematic review reports the selected articles from five sources with the searching keywords: “(Metabolic associated fatty liver disease OR MAFLD) OR (Non-Alcoholic Fatty Liver Disease OR NAFLD) AND (Vitamin D OR Vitamin D Supplementation) AND (Controlled Attenuation Parameter OR CAP) AND (liver stiffness measurement OR LSM)”. Two trials (the first study used oral vitamin D supplementation [1000 IU] every day for 360 days compared with placebo, and the second study used intramuscular vitamin D supplementation [200,000 IU] every month for 180 days compared with placebo) report that vitamin D supplementation can significantly decrease (p < 0.05) the controlled attenuation parameter or CAP (22.8-39.1 dB/m) and liver stiffness measurement or LSM (0.07-0.52 kPa) compared to control group. The mechanism of its efficacy is achieved by inhibiting the progression of liver fibrosis induced by stellate cells after its binding to the hepatocyte. In conclusion, the efficacy of vitamin D in decreasing liver steatosis and fibrosis in MAFLD has been proven. However, the limitations of these studies should be followed by further research to state the recommendation of vitamin D supplementation in MAFLD.

Lifestyle modification programme for HIV-infected patients with NAFLD: A randomized controlled trial

Guanlin LI1,2,3, Vincent Wai Sun WONG1,2,3, Daisy Man Ching SIN2, Grace Lai-Hung Wong WONG1,2,3, Terry Cheuk-Fung YIP2, Vivian WONG1,4, Catherine CHEUNG0, Grace Chung Yan LUI1,2,4
1Department of Medicine and Therapeutics, The Chinese University of Hong Kong Hong Kong China, 2Department of Medicine and Therapeutics, Medical Data Analytics Centre (MDAC), The Chinese University of Hong Kong Hong Kong China, 3Faculty of Medicine, Institute of Digestive Disease, The Chinese University of Hong Kong Hong Kong China, 4Faculty of Medicine, Stanley Ho Centre for Emerging Infectious Diseases, Jockey Club School of Public Health & Primary Care, The Chinese University of Hong Kong Hong Kong China, 5School of Life Sciences, The Chinese University of Hong Kong Hong Kong China

Background: Lifestyle modification directing at weight loss is currently the cornerstone of treatment for fatty liver disease in the general population. No studies have been performed to specifically evaluate the efficacy of lifestyle modification programmes targeting non-alcoholic fatty liver disease (NAFLD) in people living with human immunodeficiency virus (HIV) (PLWH).

Objectives: To assess lifestyle modification programme in inducing resolution of NAFLD in PLWH.

Methods: This is a single-blinded randomized controlled trial. 84 PLWH with NAFLD in Hong Kong were randomly assigned to either receive a lifestyle modification programme or standard care for 12 months. The primary outcome is the resolution of NAFLD as determined by proton magnetic resonance spectroscopy (1H-MRS) at month 12. Resolution of NAFLD is defined as intrahepatic triglyceride (IHTG) content less than 5%.

Results: 43 patients were randomized to the intervention group and 41 patients to the control group. 77 patients completed all assessments during 12-month intervention. In the intention-to-treat analysis, 12 (27.9%) patients in the intervention group and 4 (9.8%) in the control group achieved the resolution of NAFLD (p = 0.034). The mean reduction of IHTG was significantly higher in the intervention group (5.1±7.1%) compared to the control group (0.2±6.9%) (P = 0.004). The mean change of total body fat was significantly higher in the intervention group (-1.81±2.97 Kg) compared to the control group (+0.10±1.78 Kg) (P = 0.001).

Conclusion: Lifestyle modification programme has efficacy in inducing resolution of NAFLD in PLWH.
The effects of lifestyle modification interventions on self-efficacy among NAFLD patients: SR

Angel Cho Kan Ma1,2, Wai Lin William Tse1,3, Ka Ming Chow1

1The Nethersole School of Nursing, Faculty of Medicine, The Chinese University of Hong Kong, Hong Kong SAR, China Hong Kong Hong Kong, 2Department of Medicine and Therapeutics, Prince of Wales Hospital, Hospital Authority, Hong Kong SAR, China Hong Kong Hong Kong, 3Department of Surgery, North District Hospital, Hospital Authority, Hong Kong SAR, China Hong Kong Hong Kong

Background: Patients with NAFLD reported low self-efficacy, poor illness perception and self-management behaviours which would affect the disease progression. Lifestyle modification has been regarded as the first-line therapies to NAFLD. However, no studies have been conducted to investigate the effects of lifestyle modification interventions on these outcomes, and there is no consistent design of such intervention for the patients.

Methods: A systematic literature search was conducted in nine electronic databases. Meta-analyses was conducted to pool the quantitative results from comparable studies.

Results: The review included 16 randomised controlled trials. The meta-analysis results indicated that the lifestyle modification interventions significantly improve general self-efficacy (standardised mean difference [SMD] = 0.82, 95% confidence interval [CI] [0.27, 1.38], p = .0004, I2 = 71%), self-management behaviours (SMD = 7.91, 95% CI [5.74, 10.07], p < .00001, I2 = 96%), dietary behaviours (SMD = 2.33, 95% CI [1.15, 3.51], p = .0001, I2 = 97%), total physical activity (SMD = 1.36, 95% CI [0.57, 2.14], p = .0007, I2 = 96%), and steatosis grade (SMD = 0.56, 95% CI [-0.80, -0.31], p < .00001, I2 = 0%). Individual studies suggested significant improvement in illness perception (p < .001). The overall methodological quality of the included studies was average.

Conclusion: Lifestyle modification interventions were found to be effective in improving self-efficacy, illness perception, self-management behaviours and steatosis grade among patients with NAFLD. Suggested design of the intervention has also been identified but more rigorous trials should be conducted to evaluate the effects of the interventions.

Fibrosis-Associated Genetic Variants in Metabolic Dysfunction-Associated Steatotic Liver Disease.

Yun Zheng Gao1, Xia-Rong Liu1, Yi-Ting Chen1, Szu-Ching Yin1, Tsu-I Chen1, Mei-Hsuan Lee1

1Institute of Clinical Medicine, National Yang Ming Chiao Tung University Taipei Taiwan

Abstract

Background and aim: The study aimed to investigate genetic variants associated with liver fibrosis among individuals with metabolic dysfunction-associated steatotic liver disease (MASLD).

Method: The study included 31,389 individuals with MASLD from Taiwan Biobank, defined by a fatty liver index ≥30 and the presence of any cardiometabolic risk factor. Fibrosis was assessed using the fibrosis index-4 (FIB-4), categorizing participants with FIB-4 ≥1.45 as having mild fibrosis and FIB-4 <1.45 as non-fibrosis. Logistic regressions were used to estimate the odds ratios (ORs) with 95% confidence intervals (CIs) on potential risk factors and fibrosis-associated genetic variants among the individuals with MASLD.

Results: Among individuals with MASLD, 6711 (21.4%) had FIB-4 ≥1.45. Advanced age, male, and comorbidities were positively associated with mild fibrosis (p<0.05). Variants in PNPLA3 and GCKR genes showed significant associations with fibrosis in MASLD individuals (p<0.001). Variants on PNPLA3, GCKR and TM6SF2 genes were examined, and the numbers of risk alleles were calculated. Individuals with more risk alleles were more likely to have fibrosis. Categorizing the number of alleles as 0-1, 2, and ≥3, the adjusted OR (95% CI) was 1.23 (1.15, 1.31) for risk allele(s) ≤3 and 1.14 (1.07-1.22) for 2 risk alleles. The trend remained significant in individuals with MASLD and obese (BMI≥24 kg/m2), the findings were consistent, with an adjusted OR of 1.14 (1.06-1.22) for 2 risk alleles, and 1.22 (1.13-1.31) for risk allele(s) ≥3.

Conclusion: Individuals with MASLD, carried a higher number of risk alleles at increased risk of mild fibrosis, highlighting the importance of intensive care and monitoring.

Change in Fibrosis-4 Index (FIB-4) over time is associated with subsequent risk of liver events

Kamal Kant Mangla1, Quentin M. Anstee2,3, Tina L. Berentzen1, Louise M. Nitze1, Maximilian Jara1, Anders Jensen1, Mette S. Kjær1, Jens M. Tarp1, Kamlesh Khunti4

1Novo Nordisk A/S Søborg Denmark, 2Translational & Clinical Research Institute, Faculty of Medical Sciences, Newcastle University Newcastle upon Tyne United Kingdom, 3Newcastle NIHR Biomedical Research Centre, Newcastle upon Tyne Hospitals NHS Trust Newcastle upon Tyne United Kingdom, 4Diabetes Research Centre, University of Leicester, Leicester General Hospital Leicester United Kingdom

Background: Tools assessing morbidity/mortality risk of non-alcoholic steatohepatitis (NASH) are lacking. We evaluated associations between changes in fibrosis-4 index (AFIB4) and subsequent liver events.

Methods: This longitudinal study included adults with obesity and/or type 2 diabetes (T2D); ≥2 FIB4 measurements; no alcohol-related and/or chronic liver diseases (except non-alcoholic fatty liver disease/NASH). ΔFIB4 was calculated using baseline and 12-month scores. Follow-up included time from second measurement until first liver event, first cardiovascular event, all-cause mortality, 10 years' follow-up; or 1/1/2020.

Results: Among 20,443 patients, there were 466 liver events. After 10 years, patients with high baseline FIB4 (≥2.67) had a 12.8% risk of a liver event; the risk was 18.5% or 10.1% when FIB4 increased or decreased after 12 months, respectively. In patients with indeterminate (1.30-2.67) or low (<1.30) FIB4, increasing FIB4 was associated with increased risk. AFIB4 was directly associated with risk of liver event, dependent on baseline FIB4 (Cox models). Compared with low baseline FIB4 and no change in FIB4 (reference), the hazard ratio (95% confidence interval) in patients with high baseline FIB4 was 24.27 (16.98; 34.68) with 1-unit FIB4 increase; and 10.90 (7.90; 15.05) with 1-unit decrease. Patients with indeterminate/low FIB4 and 1-unit increase/decrease had significantly higher/lower risk compared with the reference group. Similar results were seen for cardiovascular events/mortality.

Conclusion: In patients with obesity and/or T2D, a 12-month increase/decrease in FIB4 was associated with higher/lower risk of
NASH-related liver events across FIB4 groups, highlighting FIB4’s potential to identify patients at risk of severe events.

Effect of metabolic dysfunction-associated steatotic liver disease on BNT162b2 immunogenicity

Lok Ka Lam1,2, Jing Tong Tan1, Wai Kay Seto1,2,3, Man Fung Yuen1,2, Ka Shing Cheung4

1Queen Mary Hospital Hong Kong Hong Kong, 2School of Clinical Medicine, The University of Hong Kong Hong Kong, 3The University of Hong Kong-Shenzhen Hospital Shenzhen China

Background: We aimed to investigate effect of metabolic dysfunction-associated steatotic liver disease (MASLD) on COVID-19 vaccine immunogenicity to omicron variant.

Methods: Adult recipients of three doses of BNT162b2 were prospectively recruited from vaccination centers between May and December 2021. Serology of neutralising antibody by live virus microneutralization (vMN) to omicron variant was measured at baseline, day 180 and day 360 after first dose (Figure 1). Study outcome was seroconversion (vMN titer ≥10) at day 360 after first dose. Exposure of interest was MASLD. Hepatic steatosis was defined by controlled attenuation parameter (CAP) ≥248 dB/M on transient elastography. Subjects with infection prior to one-year follow-up were excluded. Multivariable logistic regression model was used to derive adjusted odds ratio (aOR) of seroconversion with MASLD by adjusting for age, sex, antibiotic and proton pump inhibitor use.

Results: 148 BNT162b2 recipients (male:48 [32.4%]; median age:51.0 years [IQR:44.5-57.3]) were recruited. The median time from first dose to third dose was 8.5 months (IQR:7.9-8.9). Only 4 [2.7%] subjects were seropositive at day 180. MASLD subjects had lower seroconversion rate than non-MASLD ones (89.6% vs 99.0%;p=0.007) (Table 1; Figure 2a). MASLD was the only independent risk factor associated with lower odds of seroconversion (aOR:0.95; CI:0.002-0.44). Subgroup analysis shows MASLD subjects had lower vMN titer [13.06 [IQR:7.69-22.20] vs 33.49 [IQR:24.05-46.53];p=0.004] and seroconversion rate (76.9% vs 97.4%;p=0.016) than non-MASLD subjects after 4 months from third dose but not within 4 months (Table 1; Figure 2b).

Conclusions: MASLD was associated with lower vaccine immunogenicity to omicron variant after three doses of BNT162b2.

Insulin resistance in MASLD and liver-related outcomes: a nationwide, population-based study

Yang Hyun Bae1, Yewool Kang1, Sang Yi Moon1, Min Kook Son1

1Dong-A university hospital Busan South Korea

Aims: Insulin resistance is a well-known factor in patients with metabolic syndrome or steatotic liver disease. Surrogate markers such as the triglyceride-glucose (TyG) index and triglyceride to high-density lipoprotein cholesterol (TG/HDL-C) ratio assess insulin resistance (IR). In this study, our aim was to investigate the relationship between insulin resistance and factors in patients with metabolic associated steatotic liver disease (MASLD).

Methods: Using data from participants who underwent health screening in 2009 and 2010, we divided them into quartiles (Q1, Q2, Q3, Q4) for each marker and compared the incidence rates of liver-related diseases during the observation period.

Results: Among a total of 362,285 patients, 67,908 patients deemed suitable for this study were enrolled and followed-up for an average of 9.4 years. During this period, liver-related diseases occurred in 2,621 cases of decompensated cirrhosis and 2,056 cases of liver cancer. Participants were divided into 4 quartiles according to TyG and TG/HDL-C ratio, and the incidence rate of liver-related diseases was analyzed. As a result of the analysis, it was confirmed that TyG and TG/HDL-ratio all had an inverse proportional relationship in which the incidence of liver-related diseases decreased as IR increased.

Conclusion: Our study showed that TyG and TG/HDL ratio are inversely related to liver-related diseases in MASLD patients, which indirectly suggests nutritional imbalance and decreased function of liver mediators during liver fibrosis progression. Improvement in metabolic parameters in MASLD patients suggests that liver-related diseases should be reassessed.

NFTE- A Prediction rule for fibrosis in Metabolic-dysfunction associated steatotic liver disease

Gayathri Shivakumar1, Jithin John2, Ann Mary George3, Sreekumar S2, Yamuna R Pillai2, Srijaya S2, Krishnadas Devadas2, Adithya Verma2, Jacob Raja2

1Government medical college, Thiruvananthapuram Thiruvananthapuram India, 2Goverment Medical college, Thiruvananthapuram Thiruvananthapuram India

Background: Accurate evaluation of liver fibrosis in Metabolic-dysfunction Associated Steatotic-Liver-Disease(MASLD) serves as a surrogate to predict liver-related outcomes. We evaluated the diagnostic performance of non-invasive tests(NITs) in detecting advanced fibrosis(AF) and tried to optimize diagnostic strategies for improved outcomes and reduce the need for liver biopsies.

Materials and Methods: Consecutive patients with biopsy-proven MASLD from September 2021 to March 2023 were enrolled. NITs were compared with histological grade of fibrosis(NASH-CN) for diagnostic accuracy. Biomarkers were assessed individually and in paired combinations. Liver stiffness(LSM) was measured using 2D-Shear-Wave-Elastography(SWE) and Vibration-Controlled-Transient-Elastography (VCTE). Results: 92 patients (53 male[57%], median age 41 years were included. 64(69%) had biopsy-proven AF. T2DM present in 55(59%).Advanced age, male sex, lower platelet counts, and high triglyceride were significantly associated with advanced fibrosis(p<0.001). NITs were moderately accurate in predicting advanced fibrosis while using previously published cut-offs. Newly derived cut-offs demonstrated a high positive predictive value(93%) to ruling in advanced fibrosis. The AUROCs of NAFLD Fibrosis Score(NFS), SWE, Aspartate-Aminotransferase-Platelet-Ratio-Index(APRI), VCTE, Fibrosis-index-4-Factors(FIB-4) and BARD were 0.94, 0.93, 0.93, 0.91, 0.90 and 0.88 respectively at newer cut-off. A New score derived by combining NITs- NFS and VCTE, namely the NF-TE demonstrated significant diagnostic accuracy(AUROCC0.98) and discriminative power (p<0.05) when compared with individual NITs.

Conclusion: NITs are point-of-care strategies to assess hepatic fibrosis in MASLD. FIB-4 and NFS may require age-dependent novel cut-off points for adequate estimation of fibrosis. Combination NIT serves as an important adjunct to rule in advanced fibrosis, thereby alleviating the need for liver biopsy.
Development of a novel supervised machine learning algorithm predicting MASLD in research volunteers

Jorg Taubel¹, 2, 3, 4, James Rickard¹, 3, Thomas York¹, 4, 5, Bronagh McCann¹

¹Richmond Research Institute London United Kingdom, ²St George’s, University of London London United Kingdom, ³King’s College London London United Kingdom, ⁴Richmond Pharmacology Ltd London United Kingdom, ⁵Imperial College London London United Kingdom

Background and Aims: Metabolic dysfunction-Associated Steatotic Liver Disease (MASLD) affects approximately one in four of the global adult population. MASLD has important implications for clinical trial volunteers as an occult co-morbid condition - there is evidence that MASLD modulates drug metabolism, with studies suggesting that Grade 3-4 liver reactions are four times more common in healthy volunteers with probable MASLD. This research aims to develop a non-invasive, low-cost tool, utilising supervised machine learning techniques, to predict MASLD in a healthy volunteer population, enabling the stratification of this sub-population in early phase trials.

Method: This is an observational cross-sectional study, with a total of 1500 subjects. Assessments include bioimpedance vector analysis, BMI, waist circumference, and laboratory bloods (including HbA1c, liver enzymes and White cell count). FibroScan is performed as a pragmatic 'outcome' for MASLD.

In this interim analysis of 1243 volunteers, a logistic regression model was trained using 70% of data for the ability to predict the outcome of the FibroScan from a data subset containing: Age, Sex, Ethnicity/Race, Height, Weight, BMI, Waist Circumference, and Body Fat Percentage. The programming language R was used to build the model.

Results: The 663 steatotic patients were categorized into: 6(0.9%) NAFLD, 326(49.2%) MASLD, 325(49%) NAFLD-MASLD, and 6(0.9%) not NAFLD-MASLD. Among patients meeting MASLD criteria, majority (80%) met ≥2 cardiometabolic criteria while only a minority (8.3%) satisfied only 1 criterion, of which overweight/obesity (79.6%) was most common. NAFLD-MASLD and MASLD patients had higher ALT, AST and platelet levels as compared to NAFLD and not NAFLD-MASLD patients (p<0.05). A higher probability of advanced fibrosis was seen in MASLD only compared to the other groups using APRI. There was a trend for more no/minimal fibrosis patients in the NAFLD and not NAFLD-MASLD groups compared to the MASLD and NAFLD-MASLD groups using non-invasive liver fibrosis tests.

Conclusions: Majority (98.2%) of patients with steatosis on ultrasound meet MASLD criteria. Serial follow-up is needed to determine if patients who do not meet MASLD criteria now will meet it in the future.

Effect of Lifestyle Measures in Normal Body Mass Index NonAlcoholic Fatty Liver Disease Patients

Sudhir Maharsi¹, Saksham Sethi¹, Shyam Sunder Sharma¹

¹Department of Gastroenterology, SMS Medical College, Jaipur, India Jaipur India

Background and Aims: Lean nonalcoholic fatty liver disease (NAFLD) is a distinct entity shaped by the dynamic interaction of genetic predisposition, metabolic dysregulation, gut microbiota and enterohepatic circulation. There is paucity of data on effects of lifestyle measures in lean NAFLD patients. Our aim was to study the effects of lifestyle measures in normal body mass index (BMI) patients with NAFLD.

Methods: This prospective interventional study was conducted on patients of NAFLD patients with normal BMI, who were divided in to cases who received healthy lifestyle measures in the form of diet [low fat, low carbohydrates, high fiber and high protein (1-1.5g/kg body weight) with total 15-20kcal/kg/day] and exercise (150-200 minutes/week moderate intensity over 3-5 sessions) along with standard medical therapy and controls who received standard medical therapy only, for 6 months.

Results: A total of 120 patients, 60 cases (31 males, age 37.41± 17.4 years) and 60 controls (27 males, age 41.81 ± 16.8 years) were enrolled. Baseline parameters, co-morbid conditions and grade of fatty liver were similar in both the groups. Improvement in SGOT (ΔSGOT - 16.6±6.8 vs -1.2±1.1, p=0.001), SGPT (ΔSGPT-23.24±8.8 vs -4.3±2.8, P= 0.001), controlled attenuation parameter (CAP) score (ΔCAP - 36.6±13.8 vs -6.9±5.2, p=0.001), was observed in cases compared to controls at the end of study. However, the improvement in liver stiffness measurement (LSM) (ΔLSM -0.8±0.6 vs -4.6±0.4, p= 0.45) was comparable in both cases and controls.

Conclusion: Lifestyle modifications and dietary intervention is effective for lean NAFLD patients.
Low Accuracy of Noninvasive Tests for Screening for advanced Fibrosis Among Chinese Adults With MAFLD
He Yi1, 2, Ling Li1, 2
1Southeast University School of Medicine NanJing China, 2Zhongda Hospital Southeast University NanJing China

Background: Fibrosis-4 (FIB-4), the nonalcoholic fatty liver disease fibrosis score (NFS) and aspartate aminotransferase to platelet index (APRI) are popular non-invasive tests (NITs) for fibrosis screening. In this study, we aimed to evaluate the accuracy of these simple NITs for advanced fibrosis in MAFLD.

Method: We conducted a multicentered, cross-sectional study comprising 980 adult inpatients with MAFLD. Hepatic steatosis and fibrosis were assessed by transient elastography to measure CAP and LSM, respectively. We evaluated the correlation between NITs and LSM. The diagnostic performance of NITs was assessed.

Result: The mean [SD] age was 57.5 [13.9] years and 58.7% were male. There was a significant but weak correlation between LSM values and APRI (Spearman’s rho = 0.261, p<0.001) and FIB-4 (Spearman’s rho = 0.174, p<0.001), rather than NFS (Spearman’s rho = 0.044, p=0.207). APRI had a significantly higher AUROC compared with FIB-4 and NFS for advanced fibrosis (AUROC: APRI 0.68, FIB-4 0.64, NFS 0.55, p<0.05) in MAFLD. However, APRI had the lowest sensitivity based on its cutoff values (APRI>0.5 Se 0.25; APRI>2.0 Se 0.02; p<0.05) for advanced fibrosis. We also found low cutoff values of NITs outperformed high cutoff values: FIB-4>1.3 Se 0.56, FIB-4>2.67 Se 0.17; NFS>1.45 Se 0.78, NFS>0.675 Se 0.22; all p<0.01. In addition, 16.2%, 9.5% and 4.4% false-negatives were observed in APRI, FIB-4 and NFS based on their low cutoff values for advanced fibrosis, respectively. And false-negatives accounted for higher proportion when using high cutoff values (APRI: 21.2%, FIB-4: 17.7%, NFS: 15.7%).

Conclusion: In our research, NITs had poor correlation with liver stiffness and unsatisfactory performance in AUROC (all<0.7) for advanced fibrosis. Therefore, these NITs seems inadequate to be screening tools for advanced fibrosis in patients with MAFLD from China and more appropriate cutoff points should be set.

Prevalence and risk factors of MASLD and liver fibrosis in an urban Chinese population
Mengmeng Hou1, Qi Gu2, Jie Li2, Yuemin Nan1
1Department of Traditional and Western Medical Hepatology, Hebei Medical University Third Hospital Shijiazhuang China, 2Department of infectious diseases, Nanjing Drum Tower Hospital, Affiliated Hospital of Medical School, Nanjing University Nanjing China

Backgrounds: With societal development and lifestyle changes, metabolic associated fatty liver disease (MAFLD) becomes the most common chronic liver disease worldwide, affecting almost a quarter of the global population. This study aimed to investigate the prevalence and characteristics of MAFLD and liver fibrosis in China, and identify the risk factors for liver fibrosis in MAFLD patients.

Methods: Participants were enrolled from a physical examination center of The Third Hospital of Hebei Medical University from May 2019 to March 2023. General data, laboratory biochemical parameters and abdominal ultrasonography were explored. MAFLD diagnosis followed clinical practice guidelines. Hepatic fibrosis was assessed by the fibrosis-4 index score (FIB-4, significant fibrosis was defined as FIB-4≥1.3). Binary logistic regression was used to determine the risk factors for significant fibrosis of MAFLD.

Results: A total of 22970 participants were included in the final analysis. The overall prevalence of MAFLD was 28.77%, of which 16.87% of MAFLD patients had significant fibrosis. Moreover, lean MAFLD patients had higher proportion of significant fibrosis than overweight participants. Multivariate logistic regression revealed male, overweight, hypertension, elevated liver enzymes, lipid and glucose indexes, and hypoalbuminemia were significantly associated with MAFLD, and the independent risk factors for significant fibrosis in MAFLD patients were male (OR=0.676, 95%CI 0.588-0.821; P <0.001), HBsAg positivity (OR=2.611, 95%CI 1.557-4.379; P<0.001), BMI ≥ 23kg/m2 (OR=0.632, 95%CI 0.470-0.851; P=0.002), BP ≥ 130/85 mmHg (OR=1.885, 95%CI 1.564-2.272; P<0.001).

Conclusions: Approximately 16% of MAFLD patients has significant liver fibrosis, and varies among BMI, ages, genders, and metabolic status.

Background: AGILE-3+ and AGILE-4 are novel non-invasive tests for ruling-in advanced fibrosis and cirrhosis, respectively, with reduced grey-zone. They incorporate age, gender, AST, ALT, platelet count, diabetic status and liver stiffness measurement (LSM) on transient elastography.

Methods: In an on-going real-life study of ICON-D, interim data across 42 centres over 4 years (n=8043), data of all patients with liver-biopsy (n=381, 63.2% males, age:42(33-50) were analysed to explore the diagnostic performance of AGILE-3+ and AGILE-4.

Results: Advanced fibrosis (F≥3) and cirrhosis (F4) were present in 70 (18.3%) and 39 (9.97%) patients, respectively. AGILE-3+ showed good calibration (p=0.474 on Hosmer-Lemeshow test, 95% CI of slope: 0.82-1.218, 95% CI of x-intercept: -0.05 to 0.04) with an AUROC of [0.78(95% CI:0.74-0.82)] for F≥3 which was significantly better than APRI, NFS and FIB-4 but not LSM. The proportion of patients falling in the grey zone with AGILE3+ (12.07%) was significantly less than with APRI, FIB-4, NFS and LSM.

AGILE-4 showed good calibration (p=0.147 on Hosmer-Lemeshow test, 95% CI of slope: 0.79 to 1.166, 95% CI of x-intercept: -0.041 to 0.028) with an AUROC of [0.81(95% CI:0.77 to 0.85)] for cirrhosis which was significantly better than APRI and NFS but not from FIB-4 or LSM. The proportion of patients falling in the grey zone with AGILE 4 (13.9%) was significantly less than with APRI, FIB-4, NFS and LSM.

Conclusion: The AGILE-3+ and AGILE 4 score showed AUROC for detecting advanced fibrosis and cirrhosis, and may help to decrease the grey zone.

Gut microflora composition in patients with non-alcoholic fatty liver disease

Tatia Khachidze1,2,3, Gocha Barbakadze2,3, Gela Sulaberidze2,3

1 Grigol Robakidze University Tbilisi Georgia, 2 GRUNI-School of Medicine Tbilisi Georgia, 3 Tbilisi State Medical University Tbilisi Georgia

Background and Aims: Nonalcoholic fatty liver disease (NAFLD) is the most common chronic liver and affects 25-30% of the population. Number of studies have indicated relationship between dysbiosis and NAFLD. Hence, the aim of this study was to analyze gut microbiota composition in NAFLD patients with possible examination of aggressive and protective factors, including small intestinal bacterial overgrowth existence and biochemical markers

Method: Study included 93 subjects diagnosed with NASH/NAFLD based on a fibro scan of the liver, ultrasound and biochemical tests. Stool sample examination was performed using Real time-PCR. Hydrogen breath test was performed to all patients

Results: The study’s findings were as follows: A 55.1% correlation was found between NAFLD and SIBO in the gut microbiome. The following bacteria were present: Firmicutes (46.3±1.99), Actinobacteria (26.1±18). Bacteroidetes and Firmicutes had a markedly negative connection (r = -0.89), as did the Bacteroidetes and Firmicutes/Bacteroidetes index (r = -0.74) and Bacteroidetes and Actinobacteria (r = -0.90). There was a significant association between the F/B index and ALT (r = 0.5) and triglycerides (r = 0.52). Also, middle-strong connection (r = 0.43) between the presence of SIBO and the growth of Firmicutes in NAFLD patients.

Conclusion: Increased Firmicutes and Actinobacteria are caused by decreased levels of Bacteroidetes, which raises triglycerides and ALTs in patients with NAFLD and is associated with SIBO. The F/B index may be a marker for the presence of NAFLD, while Bacteroidetes may act as potential inhibitors of NAFLD progression. Patients with NAFLD should be tested for SIBO.

COMPARISON OF FATTY LIVER INDEX WITH FIBROSCAN IN NON ALCOHOLIC FATTY LIVER DISEASE

Lubna Kamani1, Marium Ahmed1, Rabeeya Saeed4, Nooren Durrani2, Faraz Ahmed2

1 Liaquat National Hospital Karachi Pakistan

Background: Non-alcoholic fatty liver disease (NAFLD), is a global health issue. This study is to compare Fatty Liver index (FLI) values with Fibroscan in NAFLD.

METHODOLOGY: A cross-sectional study was done at gastroenterology clinics of Liaquat National Hospital, Karachi, Pakistan. Participants underwent laboratory assessments, abdominal ultrasound and Fibroscan. Those with history of alcohol intake and positive for hepatitis B and C were excluded.

RESULTS: Total 225 participants were studied (52.9%) were males. Median BMI and Waist Circumference were 29.8 kg/m² (IQR=26.9-34.2 kg/m²) and 103 cm (IQR=95-110 cm), respectively. Metabolic syndrome (MetS) was present in 139(61.8%). Mild Steatosis were not found among 115 (51.1%) patients. Significant variations in BMI, Waist Circumference, GGT levels, and Triglyceride TG levels were identified when comparing individuals with Fatty Liver Index (FLI) scores below 30 and those exceeding 60. Similar variations were observed in relation to the frequency of MetS as FLI scores increased. The agreement between FLI and ultrasound observations was found to be (k=0.077; p=0.027), and the Spearman correlation analysis indicated a statistically significant but weak positive correlation (r=0.384, p<0.001). On the multivariable regression model, participants having diabetes, elevated SGPT levels and mild disease on ultrasound were associated with increased odds of severe steatosis.

CONCLUSION: FLI is a good predictor of frequency of MetS & NAFLD and correlates well with increasing steatosis score (CAP) on fibro scan which can be utilized as an effective screening tool at primary care level for early detecting of NAFLD.

Liver Stiffness with Magnetic Resonance Elastography in Indonesia and Metabolic Dysfunction

Riki Tenggara1,3, Alver Prasetya1, Angelina Yuwono1, Herlina Unarni2,4, Sugento Sugento1, Rino Alvani Gani5

1Department of Internal Medicine, School of Medicine and Health Sciences Atma Jaya Catholic University of Indonesia Penjaringan, Indonesia, 2Department of Anatomy, School of Medicine and Health Sciences, Atma Jaya Catholic University of Indonesia, Jakarta, Indonesia, 3Department of Internal Medicine, Gastroenterology and Hepatology Division Pantai Indah Kapuk Hospital Jakarta Indonesia, 4Department of Radiology Pantai Indah Kapuk Hospital Jakarta Indonesia, 5Division of Hepatobiliary, Faculty of Medicine, University of Indonesia, Cipto Mangunkusumo General Hospital Jakarta Indonesia

Background: Metabolic Associated Fatty Liver Disease (MAFLD) is a problem in many countries around the world including Indonesia. Magnetic Resonance Elastography (MRE) is used to assess people with MAFLD particularly regarding fat accumulation and fibrosis. However, the data in Indonesia is still limited. We aim to describe the correlation between the baseline characteristics and liver stiffness of fatty liver patients in Indonesia.

Methods: This is a cross sectional retrospective study that included 46 patients with clinically diagnosed fatty liver who underwent MRE from 2021-2022. Data were collected from medical record and analyzed using Spearman’s test and Mann-Whitney U test.

Results: The liver stiffness ranged from 1.45-7.80 kPa with a geometric mean and coefficient of variation of 3.26 and 40.6%, respectively. There was correlation between mean liver stiffness with age (p = 0.047, r = 0.295), fibrosis marker FIB-4 (p < 0.001, r = 0.720), and platelets (p <0.001, r = 0.559). Hepatocellular damage is also correlated with liver stiffness (SGOT, p <0.001, r = 0.615; GGT, p = 0.002, r = 0.533; ALP, p = 0.002, r = 0.573). Likewise, metabolic marker particularly regarding glucose control (HbA1c, p = 0.015, r = 0.501), and fat metabolism (total cholesterol levels, p =0.011, r = 0.519) correlate with liver stiffness.

Conclusions: The liver stiffness in Indonesian fatty liver patients was correlated with age, liver fibrosis marker (FIB-4 score, platelets), hepatocellular damage (SGOT, GGT, ALP) and metabolic dysfunction (HbA1c and total cholesterol). This may explain the relationship between liver damage and metabolic dysfunction.

Keywords: Liver Stiffness, Fatty Liver, Magnetic Resonance Elastography, Liver Fibrosis, Indonesia

Abstract Submission No. 101460 O-0399

Saga of an Outlier: Lean MASLD in Urban, Population of Karachi, Pakistan

Aamina S Butt1, Saeed Hamid1, Asma Ahmed1, Wasim memon1

1Aga Khan University Hospital Karachi, Pakistan
2Section of Endocrinology, Department of Medicine, Aga Khan University Hospital Karachi, Pakistan
3Section of Radiology, Department of Medicine, Aga Khan University Hospital Karachi

Background: Lean steatotic liver disease (MASLD) is unique where in the absence of obesity and unrecognized traditional risk factors, diagnosis is either delayed or even overlooked; hence resulting in compromised effectiveness or complete absence of required treatment. We aim to investigate the prevalence of lean-MASLD and to compare the clinical, and metabolic characteristics of lean and obese MASLD in an urban, adult population of Pakistan.

Methods: This was a population-based cross-sectional study piggy-backed with a large community-based trial “Pakistan Diabetes Prevention Programme” conducted in collaboration with the University of Helsinki in “Karachi”, Pakistan. Approximately 20,000 residents of Karachi were screened for diabetes using systematic sampling. Individuals aged 35-75 years, having Indian Diabetes Risk Score (IDRs) score ≥ 60 were enrolled. Ultrasound liver was performed by an experienced sonologist to identify hepatic steatosis. Anthropometric measurements and laboratory investigations were carried out. Lean-MASLD was defined if BMI was <25 Kg/m^2 and obese was defined if BMI ≥ 25 Kg/m^2. The study was funded by IDF and URC, AKUH, Pakistan.

Result: Out of 1225 individuals 741(60.5%) had MASLD. Lean-MASLD was found in 128(17.2%). Comparing lean with obese MASLD higher proportion of males, smaller waist circumferences, and lower ranges of metabolic factors were found in a lean group (table 1). The risk estimates for lean-MASLD were higher among smokers, subjects having larger waist circumference, HTN, elevated LDL, and ALT (Table 2).

Conclusion: Lean MASLD is common in the South Asian urban community of Pakistan. In the absence of significant metabolic derangements, early detection of lean-MASLD is challenging.

Abstract Submission No. 101465 O-0400

Sequential use of LSM and AGILE 3+ for assessing cACLD: Indian Consortium on NAFLD (ICON-D) study

Arka De1, Ajay Duseja1, Manu Mehta1, SP Singh2, Shrikant Mukewar3, Saurabh Mukewar1, Dr Shalimar1, Omesh Goyal3, Jayanthi Venkataraman4, VK Dixit5, Krishandas Devadas6, Varun Mehta7, Piyush Ranjan8, Anil Arora9, Aabha Nagral10

1MD, DM Chandigarh India, 2SCB Medical College Cuttack India, 3MIDAS Hospital Nagpur India, 4All India Institute of Medical Education and Research New Delhi India, 5Dayanand Medical
College Ludhiana India, 1Sri Ram Chandar Medical College Chennai India, 1SMS,Banaras Hindu University Banaras India, 2Goverment Medical College Trivandum India, 3Sir Gangaram hospital New Delhi India, 4Jaslok Hospital Mumbai India.

**Background:** Despite high sensitivity, LSM has relatively lower specificity and is more suited to ruling-out CALD (F≥3). AGILE 3+ is a novel LSM-based score, specifically designed to have high specificity for detecting F≥3 and LSM with a reduced grey-zone. We compared the diagnostic performance of combination of sequential LSM followed by AGILE 3+ with either of the methods alone.

**Methods:** In this ongoing real-life study, covering 42 centers over 4 years (n=8043), data of all patients with liver-biopsy (n=381, 63.2% males, age:42(33-50) were analysed. LSM cut-offs of <8 kPa and >12 kPa were used for ruling-out and ruling-in F≥3, respectively. Corresponding cut-offs for AGILE 3+ were <0.251 and >0.565. Similar cut-offs were used in the combined sequential approach where AGILE 3+ was applied when F≥3 was not ruled-out on LSM.

**Results:** F≥3 was present in 70 (18.3%) patients. AUROCs of AGILE-3+ with either of the methods alone. AUROCs of AGILE-4 with either of the methods alone. AUROCs of AGILE-3+ were <0.251 and >0.565. Similar cut-offs were used in the combined sequential approach where AGILE 3+ was applied when F≥3 was not ruled-out on LSM.

**Conclusion:** Sequential use of LSM followed by AGILE 3+ optimizes use of VCTE as a point-of-care tool for assessing CALD.

**Point-of-Care Non-invasive Prediction Model for Steatotic Liver Disease: Using Bioimpedance Analysis**

JEAYEON PARK1, GOH EUN CHUNG2, YOON JUN KIM3

1Seoul National University Hospital Seoul South Korea, 2Seoul National University Hospital Healthcare System Gangnam Center Seoul South Korea

**Background/Aim:** A simple and non-invasive screening method is needed to detect hidden SLD patients, especially among young adults and those with limited healthcare access due to socioeconomic factors. In this study, we aim to provide a more accessible and convenient SLD prediction model without conventional hospital laboratory infrastructure, facilitating early detection and timely intervention.

**Methods:** We retrospectively analyzed 28,506 adults at healthcare center in South Korea for a routine check-up. Participants’ alcohol intake was assessed via a health questionnaire and their body composition measured using bioimpedance analysis. To analyze the data and make predictions, a logistic regression model was developed using machine learning algorithms.

**Results:** A total of 20,094 subjects were categorized into non-SLD and SLD groups based on the presence of fatty liver. SLD model 1 was based on age and BMI, SLD model 2 was derived from age, BMI, and body fat mass per muscle mass, and SLD model 3 consisted of age, BMI, and visceral fat mass per muscle mass. In the derivation cohort, the AUROC was 0.817 in the SLD model 1, 0.821 in the SLD model 2, and 0.820 in the SLD model 3. In the validation cohort, at the optimal upper and lower cutoff values, 86.8%, 86.9%, and 87.1% of subjects were correctly classified in SLD model 1, SLD model 2, and SLD model 3, respectively.

**Conclusion:** The three derived SLD models could be novel, validated clinical tools for mass screening of SLD.

**Frequency of MASLD and cACLd among Adults with Steatotic Liver Disease**

Ling Zhou1, Jiawei Huang1, Yali Ji1, Junying Li2, Qiaoping Wu1, Damei Zhou1, Biao Wen2, Haiyu Wang1, Jiankang Song2, Yuanjian Zhang1, Xiaofeng Zhang2, Jinjun Chen3

1National University Hospital Healthcare System Gangnam Center Seoul South Korea, 2National University Hospital Seoul South Korea, 3Seoul National University Hospital Seoul South Korea

**Background and Objectives:** Diagnostic criteria for metabolic steato-tic liver disease (MASLD) have been proposed but not validated. We investigated the clinical application of the MASLD definition by...
assessing the characteristics of its subclassifications and the associated risk of compensated advanced chronic liver disease (cACLD).

Methods: A total of 1319 outpatients with imaging or biopsy-proven hepatic steatosis, systematically screened for cardiometabolic criteria, underwent transient hepatic elastography (TE) and were enrolled. Liver stiffness ≥ 10 kPa was considered suggestive of cACLD.

Results: In the present investigation, 96.6% of SLD individuals in the current research had at least one cardiometabolic risk factor, of which 36.9% had MASLD, 46.2% VSLD (MASLD + viral hepatitis), 4.02% MetALD (MASLD + significant alcohol consumption), 2.05% ALD, and 0.76% cryptogenic SLD. 97.99% of patients with NAFLD met MASLD criteria. The possible presence of cACLD was detected in 11.7% (57/487), 25.89% (80/309) and 35.8% (19/53) of those with MASLD, VSLD with SVR and MetALD, respectively. Most importantly, metabolic dysfunction was found in over 97% (229/235) of these SLD adults with cACLD. Type 2 diabetes, older age, having a higher BMI and AST were all revealed to be independent risk factors for cACLD in MASLD patients. Patients with VSLD (with SVR) who had lower PLT counts and higher AST levels were more likely to have cACLD.

Conclusions: Metabolic dysfunction was observed in most of SLD patients in China. More than half of them had viral hepatitis with viral suppression and a significant percentage of cACLD.

Abstract Submission No. 101500

Different minimal alcohol consumption in male and female individuals with MAFLD

Jie Li1,2,3,4, Yixuan Zhu2, Xiaoming Xu3, Zhiwen Fan1, Xiaoyan Hangzhou China, 6Karsh Division of Gastroenterology and of Hepatology and Metabolic Disease, Hangzhou Normal University

Background & Aims: The relationship between moderate alcohol intake and health outcomes among individuals with Metabolic Dysfunction-Associated Fatty Liver Disease (MAFLD) is complex. Our aim was to investigate the association of minimal alcohol consumption with all-cause and cause-specific mortality among MAFLD individuals of different genders.

Methods: Our study included 2630 MAFLD individuals from the Third National Health and Nutrition Examination Survey (NHANES III). Cox regression analysis was performed to assess the association between alcohol use measures and all-cause and cause-specific mortality. Restricted cubic spline curves were used to evaluate the relationship between alcohol consumption per week and all-cause mortality.

Results: In the entire MAFLD cohort, we observed significant disparities in clinical characteristics between male and female individuals with MAFLD. Higher weekly alcohol consumption was significantly associated with all-cause and cause-specific mortality, male, HRs: 1.009, 95% CIs: 1.004-1.014; female, HRs: 1.032, 95% CIs: 1.022-1.042. In males with MAFLD, a linear association with all-cause mortality was observed for weekly alcohol consumption (P for Non-linearity <0.05).

Conclusions: Our findings indicate that any increase in weekly alcohol consumption was associated with increased all-cause mortality in men with MAFLD. Conversely, consuming less than 2 drinks per week had minimal impact on the risk of mortality among female.

Abstract Submission No. 101512
O-0406

Vitamin intake and the progression of metabolic dysfunction-associated fatty liver disease

Jie Li, renling yao, yixuan zhu

Background & Aims: Obesity and associated comorbidities are reaching pandemic proportions worldwide. Non-alcoholic liver disease is hepatic component of this metabolic syndrome and has been recognized as leading etiology for HCC and a large societal & health problem. Aim of this study is to evaluate hepatic fibrosis stage in MAFLD by non-invasive markers as well as outcomes of patients undergoing treatment respectively, focusing on improvement of fibrosis stage of liver.

Method: Patients were pooled prospectively on a Questionnaire. Demographic data like age, sex, comorbidities like HTN, DM, ischemic heart disease, PCOs disease in females. Laboratory findings were included like Complete blood picture, LFTs, HbA1c, TSH, Cr, serum albumin, fasting lipid profile. Baseline Ultrasonography of abdomen & Fibroscan were part of scanning records. This nomogram map predicts the probability of severity of hepatic fibrosis in MAFLD patients. For each covariate, record the value & notedown corresponding points. This is repeated for each covariate ending total score that corresponds to the severity of hepatic fibrosis. For females total score can count upto 31 & for male 30 respectively. New MAFLD diagnostic pathways with use of this nomogram were modelled to diagnose & treat respectively.

Results: 100 patients were enrolled with suspected MAFLD. By using non invasive markers available in different studies to predict fibrosis stage it can be concluded that treatment can be allocated to patients depending on these scores safely so Prediction in these patients was optimised by stratifying patients into three categories based on scores (<7, 7-24 & ≥25). Multivariable logistic regression analyses revealed that DM, central obesity & increased cholesterol levels were independent risk factors for mortality after liver transplant. The receiver operating characteristic curve of nomogram prediction model was 0.896 (96% CI: 0.803-0.989), & mean absolute error of internal validation by bootstrap (1000 replications) was 0.019 (n=184). These results showed that nomogram model had an excellent prediction accuracy.

Conclusion: A nomogram model can provide clinicians to accurately predict severity of hepatic fibrosis by noninvasive markers & treatment allocation in MAFLD patients.
Introduction: Few studies explored the association between vitamin intake and metabolic dysfunction-associated fatty liver disease (MAFLD). Moreover, the existing results were contradictory. We aimed to investigate the association between dietary vitamins and all-cause mortality as well as fibrosis risk in patients with MAFLD in US.

Methods: We extracted data from the third National Health and Nutrition Examination Surveys 1988-1994. Dietary vitamins was assessed using a 24 h diet recall, including vitamin A, vitamin B6, vitamin B12, vitamin C, vitamin D, thiamin, riboflavin, folic acid and α-tocopherol. The non-alcoholic fatty liver disease fibrosis score (NFS) < -1.455 is considered as non-advanced fibrosis, while NFS ≥ -1.455 is considered as advanced fibrosis.

Results: A total of 3844 MAFLD participants were included in this study. The median time of follow-up was 310 months. 1739 participants (45.3%) were deceased during the follow-up. The intake of thiamin, riboflavin, α-tocopherol, VB6, and VB12 were significantly higher in patients with NFS-determined non-advanced fibrosis (P<0.05). After adjusting, a significantly lower risk of fibrosis was found in patients with the highest quartile (>11.5mg/d) of α-tocopherol intake compared to the lowest intake group (P<0.05). Compared to the lowest quartile group, the risk of mortality was reduced by 0.34 folds in the group consuming the highest quartile amount (>130 mg/d) of VC (HRs: 0.66, 95% CIs: 0.51-0.85, P =0.002).

Conclusions: More α-tocopherol intake reduced fibrosis grade in MAFLD patients. VC intake may reduce all-cause mortality in patients with MAFLD in US.

Abstract Submission No. 101513 O-0407

Daily water intake is protective against liver fibrosis in MAFLD
Jie Li1, renling yao1, yixuan zhu2
1Nanjing Drum Tower Hospital, Affiliated Hospital of Medical School, Nanjing University Nanjing China, 2Department of Infectious Diseases, Nanjing Drum Tower Hospital Clinical College of Nanjing Medical University Nanjing china

Background and objectives: Metabolic dysfunction-associated fatty liver disease (MAFLD) refers to liver steatosis caused by metabolic abnormalities. Water is involved in many metabolic processes. This study aimed to explore whether total daily water intake affected the liver fibrosis in MAFLD.

Patients and Methods: We extracted data from the database of the third National Health and Nutrition Examination Surveys 1988-1994 (NHANES III). The amount of water intake was assessed using a 24 h diet recall, including water A, vitamin B6, vitamin B12, vitamin C, vitamin D, thiamin, riboflavin, folic acid and α-tocopherol. The non-alcoholic fatty liver disease fibrosis score (NFS) < -1.455 is considered as non-advanced fibrosis, while NFS ≥ -1.455 is considered as advanced fibrosis.

Results: A total of 2863 MAFLD patients with FIB-4 scores were included in this study. There were 2744 cases in the FIB-4<1.3 group, including 1323 males and 1451 females, and 89 cases in the FIB-4<2.67 group, including 59 males and 30 females. Those in the FIB-4<2.67 group had significantly lower daily water intake compared to the FIB-4<1.3 group [2586 (1849, 3507) mL vs 3063 (2257, 4071) mL, p <0.001]. Further subgroup analysis revealed that when total water intake reached the third (3004-4019 mL) and fourth (>4020 mL) quartile, it became a significant protective factor against liver fibrosis in those without diabetes [T3 vs. T1, 0.207 (0.085, 0.501), p<0.001; T4 vs. T1, 0.085 (0.028, 0.262), p<0.001] and those BMI≥25 [T3 vs. T1, 0.286 (0.121, 0.677), p=0.004; T4 vs. T1, 0.424 (0.203, 0.886), p=0.023]

Conclusions: Daily total water intake of 3000 ml or more was a protective factor for liver fibrosis in MAFLD patients, especially for those in non-diabetic populations and BMI≥25.

Abstract Submission No. 101558 O-0408

Impact of dietary intervention in reversal of fibrosis in Metabolic Associated Fatty Liver Disease
Jay Toshniwal1, Archana Toshniwal1, Romesh Chawlani1
1DR TOSHNIWAL GASTRO LIVER CARE AURANGABAD India

Background-obesity, diet and MAFLD are closely associated.However,impact of diet in reversal of fibrosis needs validation. This study aims to study dietary treatment as a therapy in management of reversal of fibrosis in MAFLD.

Method- Out of 768 elastography performed from June 2022 to June 2023,Fifty Metabolic Associated Fatty Liver Disease ( MAFLD) patients with Severe steatosis and F3 or F4 fibrosis,were enrolled in the study.Age group was in range of 18 to 70 years with 25 Males and 25 Females.No patient had transaminitis.Dietary intervention in form of 6 feeds per day,low calorie diet :approximately 1500 Kilocalories per day was advised.No medication was prescribed to these patients.

Results-At the end of 3 months 47 patients were non-compliant to this dietary change.Only 3 patients followed this dietary advise.Weight loss of 5 kg or more was noted in all these 3 patients.Repeat elastography at end of 3 months demonstrated F0 fibrosis and no steatosis in all these 3 male patients.

Conclusion-Dietary intervention can completely reverse fibrosis and steatosis in patient with MAFLD;however,patient compliance to change the dietary pattern is very poor(6%).So,drugs like saroglitazona to be considered in all patients with MAFLD and F3/F4 fibrosis.

Abstract Submission No. 101637 O-0409

Metabolic-associated fatty liver disease (MAFLD) and its metrics for contributions to liver research
Maito Suoh1, Saeed Esmaill1, Mohammed Eslam4, Jacob George1
1Storr Liver Centre, The Westmead Institute for Medical Research, Westmead Hospital and The University of Sydney, Australia

Background: The international consensus to rename non-alcoholic fatty liver disease to metabolic (dysfunction)-associated fatty liver disease (MAFLD) in 2020 has been gained significant worldwide attention. The impact of the term MAFLD on the research community however has not been objectively assessed. We conducted a comprehensive survey of literature on MAFLD to understand the current trends in the research topic and country-level contributions.

Methods: We used PubMed, Scopus, and Web of Science to collect publications (articles, reviews, and editorials) written in English, published from 2020 to 10/10/2023 containing MAFLD or its fully spelled term in the titles or abstracts. Publication metrics, including numbers, publishing journals, author countries, author keywords, and cited times were analysed.

Results: 1470 MAFLD-related publications were published in 435 journals, with a steady increase in the numbers since 2020. Among the 97 countries and territories authoring the publications, China, followed
by Italy, USA, and Australia produced the greatest numbers of MAFLD publications. Country co-occurrence network analysis of 326 publications from multiple countries showed global and regional cross-country collaborations between 96 countries. Common topics from the highly cited publications were the MAFLD definition and the consequences resulting from the change in nomenclature. Apart from the terms describing fatty liver disease and its complications, top author keywords were enriched in those related to metabolic dysfunction, including obesity, metabolic syndrome, diabetes mellitus, and cardiovascular disease.

**Conclusion:** This survey provides a quantitative measure of the considerable international contribution of MAFLD to research with a focus on its relationship to metabolic dysfunction.

**Factors predicting the future incidence of fatty liver: A single-center study**

Aki Moriya¹, Teruya Nagahara¹, Yoshiaki Iwasaki², Masaharu Ando¹

¹Mitoyo General Hospital Kanonji Japan, ²Okayama University, Health Service Center Okayama Japan

**Background:** Identifying a population that requires special attention to prevent the development of fatty liver may contribute to the control of future complications.

**Methods:** We enrolled health-checkup participants without fatty liver on their first visit and performed logistic regression analyses to determine the association between various items and the incidence of fatty liver on their second visit.

**Results:** After a median follow-up period of 367 days, 278 out of 3,343 individuals (8.3%) had newly developed fatty liver. Body mass index (BMI; odds ratio, 1.196 per 1 increase; 95% confidence interval, 1.098-1.303), triglycerides (1.004 per 1 mg/dl increase, 1.001-1.007), γ-glutamyltransferase (GGT; 1.003 per 1 U/l increase, 1.001-1.007), low-density lipoprotein cholesterol (LDL-C; 1.023 per 1 mg/dl increase, 1.002-1.044), albumin (2.140 per 1 g/dl increase, 1.243-3.694), and platelet count (1.028 per 10,000/µl increase, 1.002-1.055) were independently associated with the incidence of fatty liver. ROC analysis revealed cutoffs of 22.1 for BMI (area under the curve, 0.726), 102 mg/dl for triglycerides (0.666), 19 U/l for GGT (0.648), 112 mg/dl for LDL-C (0.579), 4.5 g/dl for albumin (0.559), and 217,000/µl (0.555) for platelet count, with high values for any of these items indicating a risk of fatty liver. When 1 point was given for each item exceeding the cutoff value, the incidence of fatty liver exceeded 20% in those with a total score of 5-6, whereas it was less than 1% in those with 0-1 point.

**Conclusions:** Elevated BMI, triglycerides, GGT, LDL-C, albumin, and platelet counts may predict fatty liver development at one year.

**O-0411**

**The Association between Non-Alcoholic Fatty Liver Disease and Risk of Chronic Kidney Disease.**

Ahmed Mokhtar¹, Heba Kasem¹, Ezzat Abdallah¹, Ehab Abdelaty¹

¹Internal medicine department, Menoufia faculty of medicine Menoufia, Birket Elsaba Egypt

**Introduction:** Nonalcoholic fatty liver disease (NAFLD) is a spectrum of disorders ranging from hepatic steatosis to nonalcoholic steatohepatitis (NASH), NASH related cirrhosis and hepatocellular carcinoma (HCC). There is sparse data on the prevalence CKD in Egyptian patients with (NAFLD). Aim of the work: To estimate the prevalence of CKD in individuals with and without NAFLD. Patients and methods: a cross-sectional study was conducted on 430 patients from the Internal Medicine Department, Menoufia University Hospitals, including 215 patients with NAFLD, and 215 patients without NAFLD. NAFLD was diagnosed by abdominal ultrasonography. The liver fibrosis was assessed by NAFLD fibrosis score (NFS) and fibrosis-4 index (FIB-4). CKD was defined as an estimated glomerular filtration rate (eGFR) < 60 ml/min/1.73 m2 and/or abnormal albuminuria (urinary albumin-to-creatinine ratio > 30 mg/gm). The logistic regression analysis was performed to examine the association between NAFLD and risk of CKD.

**Results:** The prevalence of CKD and was higher in individuals with NAFLD than in those without NAFLD (38.1 % vs 7.4 %, p < 0.001). Logistic regression analysis demonstrated that both NAFLD and CKD were risk factors of each other. The presence of hypertension, and the high levels of BMI and waist circumference were the other independent risk factors of NAFLD. While the presence of DM, and the high level of BMI were the other significant risk factors of CKD in the NAFLD group.

**Conclusion:** The presence and severity of NAFLD are associated with an increased risk and severity of CKD.

**NASH complicating with T2DM can be well controlled by hepcidin inducer Laennec derived from Placenta**

YUKI HAMADA¹, Eiichi HIRANO², Keizo HANADA³, Taichi KAKU³

¹HAMADA Clinic of Gastroenterology Sapporo Japan, ²Japan Bio Products Co. Ltd. Kurume Research Center KURUME Japan, ³Japan Bio Products Co. Ltd. TOKYO Japan

**Background:** Recently it was elucidated that hepcidin, the principal regulator of iron metabolism, could express in pancreatic β-cells, of which level could be regulated by iron. This fact means that the pancreas may also contribute to the iron metabolism. In the cases of NASH complicating with T2DM, remarkable declines of serum ferritin and HbA1c were observed after treating with Laennec® (‘hepcidin inducer’ derived from placenta). Then, we examined whether Laennec® could restore the pathological background of NASH through regulating iron metabolism.

**Methods:** We divided 114 NASH cases (all complicating with T2DM, liver biopsied) into two groups retrospectively. Laennec®-treated 83cases were treated with the infusion of 2 ampules(224mg) of Laennec® 1-times/W, in addition to the ordinary liver supporting. Serum ferritin, ALT and HbA1c were measured, and liver re-biopsy was carried out to evaluate changes of iron deposition in 21 cases of NASH patients.

**Results:** By infusing Laennec®, serum ferritin level declined from 282.3±216.5 ng/ml (before medication) to 62.6±51.8(after) Wilcoxon P<0.01 in NASH patients. Serum ALT also declined from 61.4±24.2U/L to 29.6±16.3<P<0.001). HbA1c level improved from 6.6±1.1% to 5.7 ±0.8 (P<0.01). When compared these results in two groups, the changes observed in Laennec®-treated group were significantly larger than non-treated group(Mann-Whitney P<0.05). In multiplex-logistic analysis, the improvement of iron deposition in the liver correlate significantly with the decline of serum ferritin(P<0.01).
Conclusions: The improvement of NASH complicating with T2DM by the administration with Laennec® suggests the importance of iron regulation on refractory T2DM which shows the presence of hyperferritinemia.

The Role of Multiparametric US in Evaluating Advanced Fibrosis in Patients with MASLD

Katsutoshi Sugimoto1, Hiroshi Takahashi1, Tatsuya Kakegawa1, Takuya Wada1, Yu Yoshimasu1, Hiroshito Takeuchi1, Takao Itoi1
1Tokyo Medical University Tokyo Japan

Purpose: Liver fibrosis is a major prognostic factor in metabolic dysfunction-associated steatotic liver disease (MASLD), and there is a need for a non-invasive and highly accurate tool to assess advanced fibrosis. In this study, we aimed to develop a highly accurate model for identifying MASLD patients with advanced fibrosis using multiparametric ultrasound (US).

Materials and Methods: This prospective global multicenter study collected data from seven sites, including 65 biopsy-proven MASLD patients. Five US markers (shear-wave speed [SWS] in m/s, dispersion slope [DS] in m/sec/kHz, attenuation coefficient [AC] in dB/cm/Hz, normalized local variance [NLV], and the echo intensity ratio of liver to kidney [L/K ratio]) were measured using a 2D SWE system immediately before biopsy. The biopsy specimens were scored by expert pathologists from one site. Diagnostic performance was assessed using the area under the receiver operating characteristic curve (AUC) for identifying advanced fibrosis (fibrosis stage ≥ F3), and the best-fit multivariable logistic regression model for identifying patients with advanced fibrosis was determined.

Results: Sixty-five adults (mean age: 53 years ± 16 [standard deviation], 32 men) underwent a US examination. Among the five US markers, SWS and NLV enabled the appropriate identification of advanced fibrosis, with an AUC of 0.89 (95% CI: 0.80, 0.99) and 0.81 (95% CI: 0.67, 0.95), respectively. Performance of the combination of SWS and NLV was satisfactory, with an AUC of 0.91 (95% CI: 0.81, 1.00).

Conclusion: The combination of SWS and NLV improved the diagnostic performance of identifying MASLD patients with advanced fibrosis compared to SWS alone.

“Cryptogenic liver cirrhosis: the key role of metabolic-associated fatty disease NAFLD.”

Venera Rakhmetova1, Madina Kalimullina2, Temirbek Madina3, Beisenbekova Adina3
1MD, Professor of the Department of Internal Medicine NJSC “Astan Medical University”, Astana Kazakhstan, 2Astan Medical University resident 1 year Astana Kazakhstan, 3Astan Medical University resident 1 year Astana Kazakhstan

Introduction: Non-alcoholic fatty liver disease (NAFLD) is currently the leading cause of chronic liver disease worldwide and is projected to become the main cause of cirrhosis requiring liver transplantation in the next decade.

Case Description: Patient S., 56 years old, complains of aching pains in the epigastrium and right hypochondrium, bloating, unstable stool and increased fatigue. In the anamnesis there are no indications of alcohol abuse, the use of hepatotoxic drugs, burdened heredity. On examination - a patient of the correct physique, BMI - 41 kg / m², waist circumference - 120 cm. On palpation - the abdomen is enlarged due to ascites, moderate soreness in the right hypochondrium and epigastric region, the lower edge of the liver is 3 cm lower than the right costal edge, the liver is dense and sensitive on palpation. Laboratory examination: hemoglobin - 140 g / l, leukocytes - 8,4·10^9/ l, platelets - 179·10^9/ l, SOE - 12 mm/hour. Biochemical blood test: total bilirubin - 22 mmol/L, thymol sample - 7.5 units, ALT - 80 units/l, AST - 60 units/l, GGTP - 48 IU/L, alkaline phosphatase - 70 IU/L, total cholesterol - 7.08 mmol/l, triglycerides - 2.85 mmol/l, HDL - 1.07 mmol/l, LDL - 5.89 mmol/l, VLDL - 1.31 mmol/l, glucose - 5.2 mmol/l. Serum cancer markers: AFP, CA 19-9 - within normal limits. According to ultrasound: Moderate ascites. Hepatomegaly. Diffuse changes in the pancreatic parenchyma. Echo signs of pronounced diffuse changes in liver parenchyma by type of fatty infiltration and cirrhotic changes.

Higher incidence of DM inHealthy Fatty Liver Patient Of Bangladesh: Prompt Intervention Can Avert Complication

A B M Shelki Gani1, Dr Abdullah Al Mahmood2, Dr. A. F. Mohammed Shafiqui Alam3, Dr. Md. Mizanur Rahman4
1Assistant Professor of Hepatology Sheikh Hasina Medical College, Tangail, Tangail Bangladesh, 2Associate professor Department of Hepatology Chittagong Medical College Chittagong Bangladesh, 3Associate Professor Department of Pharmacology Sheikh Hasina Medical College Tangail Bangladesh, 4Junior Consultant (Medicine) Upazilla Health Complex, Kapasia Gazipur Bangladesh

Background: Lifestyle changes and urbanization is progressively increasing the number of diabetic patients globally & in South-Asian countries. DM associated health complications threaten to reduce economic gains in third world country like Bangladesh.

Methods: This cross-sectional study was conducted in Sheikh Hasina medical college, Tangail, Bangladesh from August 2022 to February 2023. A total of 92 patients with ultrasonological evidence of grade II fatty change in liver were included and evaluated. Known DM, Hypothyroidism, Alcohol abuse, HBV, HCV, Wilsons Diseases, autoimmune liver disease, hemochromatosis and any other chronic liver disease patients were excluded. Then patients were assessed for presence and absence of DM using OGTT or HbA1c as diagnostic criteria.

Results: Out of 92 patients, male was 48 and female 44. A total of 50 patients (54.3%) were newly diagnosed as DM. No significant differences were evident in DM group and non-DM group in respect to Mean age (41 years versus 38), ALT values (58.9 IU versus 60.23), AST (50.33 IU versus 36.53), TG (270 mg/dl versus 189), BMI (28.85 versus 29.29).

Conclusions: Recent study states, more than 54% of patients with grade II fatty liver were newly diagnosed with DM. If not evaluated early, they will come later with more advanced DM and related complications. Although a larger study is needed, physicians and healthcare workers in Bangladesh should be more concerned about treating such metabolic dysfunction-associated steatotic liver disease (MASLD) patients with early diagnosis of DM, prompt lifestyle interventions, and prescribing drugs if needed.

Modeling Disease Burden of Adolescent NAFLD and NASH Based on Body Mass Index

xiaoyun Lin1, JingMao Li, LingYi Huang1, LiYan Lin1, MeiZhu Hong1, Shangeng Weng1, JinShui Pan1
1the First Affiliated Hospital of Fujian Medical University fuzhou China, 2Xiamen University xiamen china, 3Mengchao Hepatobiliary Hospital of Fujian Medical University fuzhou china

Background: Currently, there is a lack of global or even country/regional level data on adolescent non-alcoholic fatty liver disease (NAFLD) prevalence. However, evidenced dose-dependent relationship exists between body mass index (BMI) and the risk of NAFLD. We aim to estimate the global and regional prevalence of adolescent NAFLD and related non-alcoholic steatohepatitis (NASH) based on BMI.

Methods: Sigmoidal fitting curves were generated between BMI and the risk of NAFLD/NASH using the data extracted from the NHANES database. With the aid of global and regional BMI data from the NCD-RisC database, adolescent NAFLD/NASH prevalence was estimated at the global, regional, and country levels from 1975 to 2016. The prevalence of adolescent NAFLD/NASH from 2017 to 2030 was also forecasted.

Results: The average NAFLD prevalence was 15.31%, and 12.68%, while the average NASH prevalence was 2.50%, and 2.47%, in boys, and girls aged 12-18, respectively. For both boys and girls, NAFLD/NASH prevalence increased with increasing BMI, and age. The global prevalence of adolescent NAFLD/NASH has gradually increased in the period from 1975 to 2016 and would maintain a similar trend between 2017 and 2030. High-income Western Countries had higher adolescent NAFLD/NASH whereas South Asia, and Sub-Saharan Africa exhibited relatively lower adolescent NAFLD/NASH prevalence.

Conclusion: The adolescent NAFLD/NASH prevalence increase year by year, and its burden varies significantly among different countries and regions. BMI is a precise predictor of NAFLD/NASH prevalence.

Correlation Between CAP Value and SYNTAX Score in Patient with Coronary Artery Disease (CAD)

Jordan Sardjan1, Cosmas Rinaldi Adithya Lesmana1, Lusiani Siregar2, Juferdy Kurniawan1, Rino Alvani Gani3
1Division of Hepatobiliary, Department of Internal Medicine, Cipto Mangunkusumo National General Hospital, Faculty of Medicine Universitas Indonesia Jakarta Pusat Indonesia, 2Division of Cardiology, Department of Internal Medicine, Cipto Mangunkusumo National General Hospital, Faculty of Medicine Universitas Indonesia Jakarta Pusat Indonesia

Background: Hepatic steatosis is an established risk factor for chronic liver disease (CLD), with cardiac-related mortality especially CAD serves as major cause of death. We aim to determine the correlation between hepatic steatosis and CAD burden.

Methods: Patients who underwent coronary angiography at Cipto Mangunkusumo Hospital catheterization laboratory from August 2022 to October 2023 with proven significant coronary occlusion were included in the study. Subsequent SYNTAX score was calculated. Liver elastography was used to assess hepatic steatosis and obtain CAP values. Patients with significant alcohol intake, viral hepatitis, HIV, other liver disease, ascites, pregnancy, and steatosis-inducing medication were excluded. All patients were subjected to clinical assessment and serum metabolic examinations.

Results: A total of 124 patients were enrolled, comprising 83.9% males, 55.6% smokers, 94.4% hypertensive, 55.6% diabetics, and 54.8% obese patients. Mean age was 59.8 years (σ = 11.1). Mean HDL-C was 38.8 mg/dL (σ = 10.8), median LDL-C and TG were 109.5 and 118.5 mg/dL respectively. 84.7% patients had multiple-vessel CAD, with median SYNTAX score 22. 52.5% patients had significant steatosis, with mean CAP 256.5 dB/m (σ = 47.3). Adjusted for confounders, a significant positive correlation between CAP and SYNTAX score was observed (r = 0.372, p < 0.0001).

Conclusions: This study suggests that hepatic steatosis correlates significantly with CAD burden. Early hepatic steatosis assessment is paramount to diminish the risk of developing CLD and its cardiac-related mortality.

Correlations of liver steatosis and fibrosis with metabolic parameters in young-onset diabetes

Ryan Herardi1,2, Chyntia Olivia Maurine Jasirwan3, Rabbinu Rangga Pribadi4, Ardy Wildan5, Dicky Levenus Tahapary2
1Department of Internal Medicine, Faculty of Medicine, Universitas Indonesia - Cipto Mangunkusumo Hospital Jakarta Indonesia, 2Department of Internal Medicine, Faculty of Medicine, Universitas Pembangunan Nasional Veteran Jakarta Jakarta Indonesia, 3Division of Hepatobiliary, Department of Internal Medicine, Faculty of Medicine, Universitas Indonesia - Cipto Mangunkusumo Hospital Jakarta Indonesia, 4Division of Gastroenterology, Department of Internal Medicine, Faculty of Medicine, Universitas Indonesia - Cipto Mangunkusumo Hospital Jakarta Indonesia, 5Division of Endocrine, Metabolism, and Diabetes, Department of Internal Medicine, Faculty of Medicine, Universitas Indonesia - Cipto Mangunkusumo Hospital Jakarta Indonesia

Background: Liver steatosis and fibrosis are markers used to evaluate Metabolic Associated Fatty Liver Disease (MAFLD) in diabetes. The aim of this study was to investigate the correlations between several metabolic parameters (including obesity, insulin resistance, dyslipidemia, and hypertension) and liver steatosis and fibrosis.

Methods: A cross-sectional study was conducted on outpatients with young-onset diabetes at Cipto Mangunkusumo Hospital, Jakarta, Indonesia, during November-December 2022. Liver steatosis, estimated through Controlled Attenuation Parameters (CAP) score (dB/m), and liver fibrosis, evaluated through Liver Stiffness Measurement (LSM) / E - score (kPa), were assessed using Vibration-Controlled Transient Elastography (Echosens (R), France). The metabolic parameters, including Body Mass Index (BMI), glycated haemoglobin, lipid profile (HDL, LDL, and triglyceride), and blood pressure, were assessed using physical examination, anthropometric measurements, and laboratory tests. Pearson or Spearman rank correlation test was performed.

Results: Sixty-two patients were included, 69.4% of which were female, and the mean age was 33.63 years (95% CI : 31.88 - 35.38 years). The CAP score showed a moderate correlation with BMI (R = 0.54; p < 0.01), triglycerides (R = 0.58; p < 0.01), HDL (R = -0.46; p < 0.01). Concurrently, the LSM / E - score exhibited a moderate correlation with BMI (R = 0.40; p < 0.01) and HDL (R = -0.41; p < 0.01).

Conclusions: The degree of liver steatosis correlates moderately with an increase in BMI, elevated triglycerides, and decrease in HDL. Meanwhile, the degree of fibrosis correlates moderately with an increase in BMI and a decrease in HDL.

Abstract Submission No. 101784
Efficacy of Saroglitazar in MASLD at 6 months, a single center observational study

Rajdeep Singh1, Gunjan Baweja1
1J P Medical Centre Chandigarh India

Introduction: Saroglitazar is the first ever drug approved in Non- Cirrhotic MASLD.

Methods: A retrospective analysis was conducted at a North Indian single setting. A total 50 patients with documented ultrasonographic fatty liver changes and dyslipidemia who were prescribed Saroglitazar 4 mg once daily for at least 6 months from May 2022 to November 2022 were retrospectively included in this data analysis. Change in CAP, LSM, AST, ALT, TG, TC, LDL, HbA1c, from baseline to 6 months was analyzed using paired t-test.

Results: The mean age of patients analyzed was 49.45 ±11.76. 58.0% were males and mean body weight 80.07 ±10.66. The baseline and follow up of CAP, LSM, AST, ALT, TG, TC, LDL and HbA1c values are given in Table 1. A significant and consistent reduction on CAP, LSM, AST, ALT, TG, TC, LDL and HbA1c was observed. No new safety signals were observed.

Conclusion: Saroglitazar 4 mg per day for 6 months has high efficacy in treating MASLD.

Abstract Submission No. 101839

Fibroscan compared to non-invasive scores in patients with non-alcoholic fatty liver disease

Priyansh Bhayani1, Sarojini Parameswaran1, Natarajan Murugan1, Kailipatt Palaniswamy1, Paramasivan Piramanayagam1
1Apollo Hospitals Chennai India

Background: Non-alcoholic fatty liver disease (NAFLD) is the most common liver disease of the twenty-first century, and is one of the leading indications for liver transplantation. In India, the prevalence of NAFLD in the general population varies from 9% to 53%. Liver biopsy is the gold standard for assessing the severity of liver fibrosis. However due to various difficulties involved with liver biopsy, it is imperative to identify different non-invasive tools that can replace liver biopsy.

Methods: A prospective observational study of 130 patients meeting the inclusion criteria for NAFLD was done for a period of 18 months. The aim was to compare different non-invasive scores (FIB-4, NFS and APRI) to Fibroscan and determine cut-offs to rule out advanced fibrosis.

Results: In the study, 76.9% of patients were males. Advanced fibrosis was seen in 12.3% of the patients. Majority of the patients with advanced fibrosis had metabolic syndrome and an abnormal glycemic status (p value <0.05). Based on the AUROC, the new cut-off for ruling out advanced fibrosis for FIB-4, NFS and APRI were 1.18, -0.9, 0.65. APRI had the best AUROC (0.768).

Conclusion: Abnormal glycemic status and metabolic syndrome were risk factors for advanced fibrosis. The newly derived cut-offs for FIB-4 score, NFS score and APRI score had a better Negative predictive value compared to original cut-offs. The newly derived cut-offs should be evaluated in larger cohort to exclude patients with advanced fibrosis in the absence of Fibroscan in a resource limited setting in India.

**Addition of Resveratrol to Orlistat Improves Elastography Parameters in Overweight**

**Aung Hlaing Bwa**, Khin Maung Win, Khin Maung Aye, Tint Swe Latt, Kyaw Soe Tun, Hardik Gandhi

1Yangon GI & Liver Centre Yangon Myanmar, 2University Of Medicine 1 Yangon Myanmar, 3University Of Medicine 2 Yangon Myanmar, 4Defense Services Medical Academy Yangon Myanmar, 5Zydus Research Centre Ahmedabad India

**Objectives:** Weight reduction improves hepatic steatosis and fibrosis. Orlistat, an approved therapy for weight management. Resveratrol, an antioxidant, may aid weight loss by enhancing energy expenditure through SIRT-1 activation.

**Materials & Methods:** 298 subjects aged >18 years with BMI > 25kg/m² were randomized into two groups: The control arm (O) received orlistat 120 mg thrice daily, and the test arm (O-R) received orlistat 120 mg + resveratrol 100 mg thrice daily for 12 weeks. Patients were followed up for 12 weeks.

**Results:** 247 subjects with a mean body weight ~80 kg completed the study with more than 80% patients achieving > 5% weight loss and accompanied by improvement in elastography parameters in 12 weeks. As compared to baseline, the O-R group exhibited a higher weight loss of -3.31 kg (p=0.001) compared to -2.92 kg (p=0.001) in the O group. The mean CAP score at 12 weeks was significantly lower in the O-R group as compared to the O group (253.16 dB/m vs 276.82 dB/m, P<0.05).

The fibrosis score was not found to be statistically significant (7.04 KPa vs 7.47 KPa).

**Conclusion:** Addition of resveratrol to orlistat provides synergistic benefits to weight loss. Subgroup with steatosis &/or fibrosis exhibited superior weight loss with the addition of resveratrol.

Abstract Submission No. 101931 O-0425

**Metabolic-Associated Fatty Liver Disease (MAFLD) as a Risk Factor of Developing Malignant Arrhythmia**

Muhammad Bilal Saifulhaq, Tohari Amin, Syifa Mustika

1Internal Medicine Department, Saiful Anwar Regional Hospital, Brawijaya University Malang Indonesia, 2Gastroenterohepatology Division of Internal Medicine Department, Saiful Anwar Regional Hospital, Brawijaya University Malang Indonesia

**Background:** Metabolic-associated fatty liver disease (MAFLD) is an emerging driver of cardiac arrhythmias and recent studies have
investigated the relationship between MAFLD and several types of arrhythmia. However, there has been no meta-analysis to summarize the existing studies of the relationship between MAFLD and malignant arrhythmia yet. This study is aimed to determine whether MAFLD is a risk factor of malignant arrhythmia.

**Methods:** According to PRISMA guidelines, we systematically searched the PUBMED and EMBASE database through October 2023 to identify all studies reporting the incidence of ventricular arrhythmia, malignant PVC, and prolonged QTc among patients with and without MAFLD. Random-effect models were used to estimate pooled odds ratio (OR), and 95% confidence intervals (CI); subgroup analyses, meta-regressions, and sensitivity analyses were additionally performed.

**Results:** A total of 9 studies with 38,813 individuals met the eligibility criteria and were included in the meta-analysis. MAFLD was associated with an increased risk of ventricular arrhythmia (OR: 2.09, 95% CI: 1.52-2.88), prolonged-QTc (OR: 1.84, 95% CI: 1.57-2.15), malignant PVC (OR: 2.5, 95% CI: 1.67-3.73) and overall pooled odds ratio of 1.94 (95% confidence interval, 1.70—2.22). We identified significant subgroup differences according to geographical location, study design, and risk of bias. Meta-regressions identified mean age and study-level characteristics as potential moderators of the risk of malignant arrhythmia.

**Conclusions:** MAFLD is an independent risk factor for developing malignant arrhythmias in the future. Further studies are required to confirm this finding and to evaluate specific arrhythmia prevention strategies in patients with MAFLD.

**O-0426**

**Comparison between 2D-US DL steatosis algorithm with Fibroscan in history proven patients**

Dar-In Tai1, Jennifer Tai1, Tse-Hwa Hsu1, Cheng-Jen Chen1, Wei-Ting Chen1, Ming-Ling Chang1, Bowen Li2, Le Lu3, Adam P Harrison1

1Chang Gung Memorial Hospital, Linkou Main Branch Taoyuan Taiwan, 2Department of Computer Science, Johns Hopkins University, Baltimore United States, 3DAMO Academy, Alibaba Group, New York, United States, 4Research Division, Riverain Technologies, Miamisburg, United States

**Background:** 2D-ultrasound is widely used in screening of liver diseases. A deep learning algorithm to quantify liver steatosis from 2D-ultrasound images may change a subjective steatosis diagnosis to an objective quantification. We evaluate a deep learning (DL) algorithm established in our previous work in patients receiving liver histology study.

**Methods:** Patients who received liver histology and Fibroscan studies between 2015 and 2023 were enrolled. 2D-ultrasound images and Fibroscan studies examined within one month of histology study were retrospectively collected. We classified images into four scanning views and applied the algorithm. Mean values from 3-5 images in each group were used for the results and correlated with histology steatosis grades.

**Results:** Totally 403 patients were included. Images from the right intercostal view (G2) were available in 370 patients. A cut-off system (0.58, 0.43 and 0.22) was established with histology grades as gold standard. This system was then applied to images from the left hepatic lobe (G1 view, N=272) and subcostal view (G4, N=191). The accuracy was between 0.824 to 0.878 from different views and steatosis grades. The area under receiver operating characteristic curve (AUROC) were between 0.910 and 0.945 among different histology steatosis grades. By multinomial logistic regression on histology steatosis grades, the DL steatosis algorithm was significantly associated with steatosis grades and better performance than continue attenuation parameter, especially in higher steatosis grades.

**Conclusion:** The DL algorithm objectively quantified liver steatosis from retrospectively collected 2D-ultrasound images. The high AUROC and accuracy warrant clinical applications.

**Metabolic dysfunction associated steatotic liver disease in a Cohort in Trivandrum India**

Shenoy KT1, 2, Leena KB2, Jayakumar Parameswaran Pillai2, 3

1Sree Gokulam Medical College and Research Foundation Trivandrum India, 2Population Health and Research Institute Trivandrum India, 3Population Health and Research Institute Trivandrum INDIA

**Introduction:** Non alcoholic fatty liver has a major public health issue in Trivandrum. We are reporting the prevalence of metabolic dysfunction associated steatotic liver disease (MAFLD) in the cohort

**Methods:** Between May 2022 to September 2023, a total of 2846 participants (aged 25 or more) were recruited to this cohort through multi-stage cluster sampling across the whole population of Trivandrum district within the state of Kerala, South India. Using the recent criteria for MAFLD, we analysed the data. Metabolic syndrome, demographic measures, anthropometric measures and biochemical profile and ultrasound assessment of the liver and liver stiffness were evaluated.

**Results:** MAFLD prevalence was 65.8% (95% CI 64-67.52%). There were 874 males and 998 females. Mean age was 51.71 years. Median Stiffness of liver >10.2 was seen in 20.5% in MAFLD compared to those without MAFLD (13.2: p<0.001). MAFLD odds ratios after adjusting for age, sex, domicile, BMI category (with normal weight as baseline), diabetes and metabolic syndrome are:

Efficacy and Safety of a Standarized Extract of Prunus Mume in Patients with MAFLD

Muhammad Umair Ahsan, Saleem-ullah Zafar

1SERVICES INSTITUTE OF MEDICAL SCIENCES(SIMS) LAHORE Pakistan, 2SERVICES INSTITUTE OF MEDICAL SCIENCES(SIMS) LAHORE PAKISTAN

Background and Aims: Extract of Prunus mume; a herbal variant and choline; a content of cell membrane have been reported to exert potentially therapeutic effect on various body conditions. Recently these two have been used in the treatment of Metabolic-associated fatty liver disease(MAFLD). But data is lacking in this regard in our region.

Patients and Methods: This was a prospective observational hospital-based study carried out on 200 patients diagnosed with Metabolic-associated fatty liver disease(MAFLD). Both males and females, aged≥18 years, were included in this study. 100 patients were kept on lifestyle modification and 100 patients were administered a tablet Revolic® (Prunus mume 150mg and choline 82.5mg) per day and the levels of ALT, AST, Triglycerides, Gamma GT, and total cholesterol were measured at the start of the treatment and then after 12 and 24 weeks. SPSS version 26.0 was used for data entry and analysis.

Results: Our study participants, the majority were females (83%) then males (17%) with a mean and SD of age was 40.49±10.59 years. At the end of treatment, a significant mean reduction of serum AST (5.21±0.9), ALT (3.21±1.42), GGT (3.88±0.2), total bilirubin (0.6±0.1), and weight (4.7±2.34) was observed in patients receiving Prunus Mume and Choline as compare to patients put on lifestyle modification, p-value <0.05. The most common side effects were the presence of gastrointestinal symptoms (12.74%) followed by headache (6.2%), anorexia (3.2%), and body aches (1.8%).

Conclusion: This study proves that Prunus Mume and Choline have beneficial effects on liver function tests in patients with MAFLD. Furthermore, this drug has a beneficial effect on better glycemic control and weight loss. The observed side effects in this study are minor, and this drug was observed to be safe in patients with MAFLD.

Keywords: Prunus Mume and Choline, MAFLD, Pakistan, lifestyle medication, side effects.

Validation of non-invasive tools for an assessment of liver fibrosis in MAFLD patients with obesity

Tonguk Teerasartipan1, Thaninee Prasoppokakorn1, Kanokwan Sonsiri1, Sombat Treeprasertsuk1

1Division of Gastroenterology, Department of Medicine, Faculty of Medicine, Chulalongkorn University Bangkok Thailand

Introduction: The role of non-invasive tests in the detection of liver fibrosis in obesity is controversial. We aimed to validate the performance of non-invasive tools evaluating liver fibrosis in obese MAFLD patients.

Methods: We retrospectively included 314 liver biopsy-proven MAFLD patients from the obesity clinic. Patients with BMI between 23-40 kg/m² and >40 kg/m² were classified as mild/moderate (n=159) and morbid obesity (n=155), respectively. Significant liver fibrosis was defined by METAVIR stage>2F2 and correlated with each non-invasive score.

Results: There were 61 (38.4%) and 17 (11%) patients with mild/moderate and morbid obesity had advanced liver fibrosis. FIB-4 score and APRI score had good performance in detecting significant liver fibrosis with AUROC of 0.702 and 0.708 for mild/moderate obesity and 0.710 and 0.738 for morbid obesity, respectively. For mild/moderate obesity, APRI≥1.5 and FIB-4≥2.67 had high positive predictive value (PPV) (83.3% and 75.0%) to rule in and APRI≥0.3 and FIB-4≥1.3 had high negative predictive value (NPV) (87.5% and 72.1%) to exclude significant liver fibrosis. For morbid obesity, none of the scores was sufficient to rule in significant fibrosis (PPV 9.3%-66.7%), oppositely all scores (FIB-4≥1.3, APRI≥0.3, NFS>1.455, BARD>2) had high NPV to exclude significant fibrosis (NPV 85.1%-93.3%).

Regarding the new score, SAFE (steatosis-associated fibrosis estimator) score≥100 had unsatisfactory performance in detecting significant fibrosis but SAFE score<0 was useful to rule out significant fibrosis.

Conclusions: FIB-4 and APRI scores were valid for liver fibrosis assessment in mild/moderate obesity, whereas current non-invasive scores had limited ability to detect liver fibrosis in morbid obesity. Further studies with a larger number of morbid obesity patients may be required.
Management, Ritsurin Hospital Takamatsu Japan, 1Department of Surgery, Ritsurin Hospital Takamatsu Japan, 2Department of Gastroenterology and Neurology, Kagawa University Faculty of Medicine Miki-cho Japan.

Background: We aimed to elucidate the clinical characteristics of non-obese patients with non-alcoholic fatty liver disease (NAFLD).

Methods: Fifty-seven NAFLD patients were enrolled in this study. Biochemical factors, body components and dietary nutrients were compared between obese and non-obese NAFLD patients at entry.

Results: Ten of the 34 (29%) males and eleven of the 23 (48%) females fulfilled the criteria of non-obesity, and six male patients and nine female patients were diagnosed as "hidden obesity". Serum urea acid levels and skeletal muscle indexes (SMIs) were significantly lower, and LDL-cholesterol levels tended to be lower in non-obese males than those in obese males. Ages at entry were significantly higher, and SMIs and bone mineral density were significantly lower in female non-obese patients compared to those in obese females. Carbohydrate intake tended to be higher in female non-obese patients than that in obese females. However, there were no significant differences in serum ALT levels and FIB4-indexes between obese and non-obese patients in both male and female.

Conclusion: These results suggest that non-obese NAFLD patients have a common characteristic of lower skeletal muscle mass in both male and female, and most of them fulfill the criteria of "hidden obesity". However, the pathogenesis of NAFLD may be slightly different between male and female non-obese patients.

Objective: The purpose of this study was to investigate whether fat deposition in the liver contributes to the development of hepatocellular carcinoma (HCC) and malignant tumors other than HCC (non-HCC malignancy).

Methods: We are prospectively studying hepatitis C patients treated with DAA for the period 2013-2023. The primary endpoint was the occurrence of all malignancies. Patients were divided into 4 groups based on liver stiffness and fat deposition by Fibroscan (FS) before treatment (Group A: low stiffness and low fat, Group B: low stiffness and high fat, Group C: high stiffness and low fat, Group D: high stiffness and high fat). The incidence of HCC and non-HCC malignancy in each group was compared.

Results: All 689 patients were prospectively observed from the start date of DAA treatment until November 30, 2023. The median observation period was 6.0 years. During the observation period, 141 malignancies occurred in 128 patients. All patients were divided into groups A 334 (51%) / B 186 (27%) / C 96 (14%) / D 55 (8%) according to FS before DAA treatment. When comparing 5-year cancer-free survival rates for the low-fat group (A+C) to the high-fat group (B+D), HCC 90.6% vs 90.2% p=0.646, non-HCC malignancy 98.8% vs 87.2% p<0.001. On the other hand, when comparing the low hardness group (A+B) and the high hardness group (C+D) in terms of 5-year cancer-free survival, HCC 94.0% vs 77.5% p<0.001, non-HCC malignancy 95.6% vs 92.4% p=0.08.

Conclusion: Baseline fat deposition as no relation HCC occurrence but closely correlation non-HCC malignancy.

MASLD and the Risk of Mortality in Diabetic Patients: A Systematic Review and Meta-analysis

Wasit Wongtrakul1, Nathinee Charatcharoenwitthaya2, Phunchai Charatcharoenwitthaya1

1Division of Gastroenterology, Department of Medicine, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand; 2Division of Endocrinology and Metabolism, Department of Medicine, Faculty of Medicine, Thammasat University Pathumthani Thailand.

The systematic review aimed to assess the risks of metabolic dysfunction-associated static liver disease (MASLD) on all-cause and cause-specific mortality in patients with type 2 diabetes mellitus (T2DM). EMBASE and MEDLINE were searched from inception to June 2022 for observational studies examining the relationship between MASLD and the risk of mortality among T2DM patients. Meta-analysis was conducted using random-effects models with hazard ratios (HRs) to quantify the risk of mortality. A total of 5,877 articles were screened, and ultimately, 12 eligible studies encompassing 368,528 T2DM patients, with a median follow-up of 8.9 years (interquartile range, 4.7-14.5), were included. Our analysis revealed a significant association between MASLD and an increased risk of all-cause mortality in T2DM patients (HR 1.28; 95% CI, 1.05-1.58; I2 = 90%). Meta-regression analyses did not show significant effects of mean age, mean body mass index, and percentage of smokers, hypertension, and hyperlipidemia on the association between MASLD and the risk of all-cause mortality. However, we found that MASLD was not significantly associated with mortality related to cardiovascular diseases (HR 1.05; 95% CI, 0.82-1.35; I2 = 0%) or cancer (HR 1.21; 95% CI, 0.41-3.51; I2 = 79%) among patients with T2DM. No publication bias was observed. This comprehensive meta-analysis provides substantial evidence supporting a significant association between MASLD and an increased risk of all-cause mortality among the T2DM population. These findings underscore the benefits of screening for MASLD in T2DM patients, aiding in the early identification of high-risk individuals and enabling risk modification strategies to improve survival.

Ferritin as a biomarker on weight reduction

Adriana Martinez-Cuazitl1, 2, Marco A. Gallaga-Rojas3, 4, Armando Pereyra-Tlamantes1, Jesús E. Rodriguez-Silverio3, Stefanny Cornejo-Hernández1, Eira Cerda-Reyes1

1Research Department, Military Central Hospital Mexico Mexico, 2Escuela Militar de Medicina Mexico Mexico, 3Hospital Central Militar Mexico Mexico, 4Escuela Graduado de Sanidad-UDEFA Mexico Mexico.
Metabolic dysfunction-associated steatotic liver disease (MASLD) is associated with metabolic syndrome, weight loss showed an improvement in steatosis in obese patients, the main goal of MASLD treatment is to prevent hepatic fibrosis. Although the gold standard for hepatic fibrosis is biopsy, some non-invasive tools as MR elastography are used. The FIB4 index did not work to follow the fibrosis changes in time dependent after weight reduction therapy; also, CAP measure is useful to determinate steatosis; serum ferritin has been studied to assist with disease diagnosis and progression since it is an acute-phase reactant and a pro-inflammatory cytokine. The main goal of the study was to evaluate the changes on ferritin after the bariatric surgery and the correlation to CAP.

Thirty-three women elected to bariatric surgery was included on the study, they do not have any other hepatic diagnosis, it was registered the FIB4, CAP and serum ferritin before bariatric surgery and 6 months later. We analysed changes using T-student or Wilcoxon test, and the correlation using Spearman test.

After 6 months all women reduce weight, serum ferritin, CAP, FIB4. Ferritin reduces from 89 ng/ml (57.5, 106.5) to 89 ng/ml (48.5, 100), and CAP from 278 dB/m (242.5, 326) to 229 dB/m (205, 303), but there is not a correlation between CAP and ferritin before surgery or at 6 months.

Ferritin as a reactant to follow changes induced by weight reduction could be useful, at 6 months but it is necessary to corroborate histological changes, suggested by CAP measure.

Short-Term LMWH for The Prevention of Early TIPS Dysfunction: A Randomised Controlled Trial

Xiaoze Wang1, Xuefeng Luo1, Yi Shen1, Jinlin Yang1, Li Yang1

1West China Hospital, Sichuan University Chengdu China

Backgrounds: Transjugular intrahepatic portosystemic shunt (TIPS) dysfunction is secondary to occlusion or stenosis of the shunt. Whether post-TIPS low molecular weight heparin (LMWH) was necessary when the polytetrafluoroethylene-covered stent was used during TIPS creation was not answered. The present study evaluated the effect of short-term use of LMWH on early TIPS dysfunction.

Methods: Between September 2015 and October 2017, consecutive eligible patients with cirrhosis and portal hypertension were randomly assigned to receive LMWH for three days after the TIPS procedure (n = 62) or not (n = 62), respectively. All patients were followed up over twelve months. The primary endpoint was the TIPS patency rate at one year. Secondary endpoints were overall survival and LMWH-related complications. This trial was registered in ClinicalTrials.gov (NCT03171727).

Results: During a median follow-up of 54.6 months, the TIPS patency rate at one year was 91.7% in the LMWH group and 93.5% in the control group (HR 1.52, 95% CI 0.78-2.99, P = 0.22). In multivariable logistic regression, stent shortening in the hepatic vein (HR 4.54; 95% CI 1.02-21.42; P=0.041) was demonstrated as an independent significant risk factor for shunt dysfunction. There were no statistically significant differences in survival (93.5% vs. 95.1% at 1 year; HR = 1.05, 95% CI 0.48-2.31, P = 0.90) or adverse events between the two groups.

Conclusion: Short-term use of LMWH after TIPS creation may not be necessary as it does not result in a distinct patency and survival benefit in covered TIPS.

Abstract Submission No. 100561

Gradual High Power Radiofrequency Ablation with Multi-electrodes for Small HCC: A Prospective Study

Jeong Min Lee1, Jaehyun Kim1, JeongHee Yoon1, Sungjun Hwang1

1Department of Radiology, Seoul National University Hospital Seoul South Korea

Background: Utilizing a separable clustered (SC) electrode and a two-channel 400W generator for gradual, stepwise high-power radiofrequency (RF) energy delivery significantly reduces electrode charring, enhancing targeted energy delivery to hepatocellular carcinoma (HCC), and potentially enhancing the efficacy and safety of radiofrequency ablation (RFA) for HCC.

Purpose: This study prospectively assesses the local tumor progression (LTP) and intrahepatic remote recurrence (IRR) rates of gradual, stepwise, high-power RFA in treating HCCs (≤4 cm).

Materials and Methods: Patients with single HCCs (≤4 cm) scheduled for treatment with RFA, were prospectively enrolled. The ablation procedure targeted the index tumor, guided by real-time US-CT/MR fusion imaging. A gradual, stepwise, high RF energy (~400W) alternately delivered to two of the three clustered electrodes. Technical success, complications, and cumulative incidences of LTP and IRR, along with RFS, were assessed and estimated using the Kaplan-Meier method.

Results: Among 110 participants (83 men and 27 women, mean age: 66.4±7.6 years), 116 HCCs (mean size: 1.65±0.59 cm) were treated with no major complications. LTP and IRR were observed in 4 and 29 patients, respectively. At a median follow-up of 41.0 months (range: 35.4-46.6 months), the estimated 1-year, 2-year, and 3-year cumulative incidences were as follows: LTP (0.9%, 3.6%, 7.0%) and IRR (13.9%, 20.5%, 31.4%). The corresponding RFS rates were: LTP (99.1%, 96.4%, 93.0%) and IRR (86.1%, 79.5%, 68.6%).

Conclusions: A gradual, incremental high-power RFA using an SC electrode demonstrates a promising, effective, and safe method for the management of small HCCs.

Abstract Submission No. 101292

Three-dimensional Ultrasound Fusion Imaging in Precise Ablation of Hepatocellular Carcinoma

Guangliang Huang1, Xiaoyan Xie1, Jiaming Liu1

1The First Affiliated Hospital of Sun Yat-Sen University Guangzhou China

Purpose: To investigate the value of three-dimensional ultrasound fusion imaging (3DUS FI) technique in thermal ablation of hepatocellular carcinoma (HCC).

Methods: A total of 57 patients with 60 HCCs with 3DUS FI-guided thermal ablation were retrospectively included in the study. 3DUS volume data of liver were acquired preoperatively by freehand scanning with the tumor and predetermined 5 mm ablative margin automatically segmented. Plan of needle placement was made through a predetermined simulated ablation zone to ensure a 5 mm ablative margin with the coverage rate towards tumor and ablative margin. With real-time ultrasound and 3DUS fusion imaging, ablation needles were placed according to the plan. After ablation, the ablation margin was immediately evaluated by the contrast-enhanced ultrasound and 3DUS fusion imaging. The rate of intraoperative supplementary ablation, [g/h] adequate ablative margin, complete response (CR), local tumor progression (LTP), recurrence-free survival (RFS) and overall survival (OS) was evaluated.
Results: According to postoperative contrast-enhanced CT or MR imaging, the complete response rate was 100% (60/60), and 83% of tumors (50/60) achieved adequate ablative margin (> 5 mm) three-dimensionally. During follow-up period of 6.0-42.6 months, LTP occurred in 5 lesions, with 1- and 2-year LTP rates to be 7.0% and 9.4%. The 1- and 2-year OS rates were 76.1% and 65.6%, and 1- and 2-year OS rates were 98.1% and 94.0%. No severe complications or ablation-related deaths were observed in any patients.

Conclusions: 3DUS FI technique may improve the needle placement of thermal ablation for HCC and reduce the rate of LTP.

Abstract Submission No. 101355
O-0442

Evaluation of RFA Therapeutic Effect Using Workstation

CHIKARA OGAWA1,2, KUDO MASATOSHI2, TAKUSHI MANABE1, MITSUSHIGE SHIBATOGE1
1Department of Gastroenterology and Hepatology Takamatsu Japan, 2Kindai University Faculty of Medicine Osaka Japan

It is important to have a larger area of ablation than the tumor and to determine the therapeutic effect of RFA in an objective and reproducible manner. In general, a comparison of CT or MRI before treatment and CT or MRI after treatment is often used to determine the therapeutic effect of RFA. However, due to differences in breath-hold, modalities, etc., it is difficult to accurately determine the treatment effect.

The workstation used in this study was a VINCENT, called SYNAPSE 3D internationally. Workstation SYNAPSE 3D is commonly used in many hospitals all over Japan.

With Synapse 3D, the tumor and post-treatment ablation area can be easily extracted. The region can be extracted automatically by dragging the diameter of the tumor and the whole tumor to be extracted in either the axial, sagittal, or coronal plane.

It is very important to tightly adjust the position of images of CECT or MRI before and after RFA to evaluate RFA response including safety margin. To evaluate current RFA response, you can just click on three corresponding points in the images of CECT or MRI before and after RFA.

And then, push the execute 2D registration, Synapsee 3D automatically adjusts instantly and easily. So, we can estimate the correct treatment response of RFA without being distracted by the difference in position between the two images.

Analysis of infectious complications after ablation of HCC and the impact on long-term survival

Ming Xu1, Yutong Zhang1, Xiaoyan Xie1
1Department of Medical Ultrasonics, the First Affiliated Hospital, Sun Yat-Sen University Guangzhou China

Purpose: This study aims to complete and detailed record of the clinical characteristics and treatment of HCC patients with post-ablation infection and evaluate the infections on recurrence-free survival (RFS) and overall survival (OS).

Methods: 3117 patients with liver tumors receiving thermal ablation from January 2010 to December 2021 were analyzed. A total of 49 patients with infectious complications after thermal ablation were selected as the infection group. 49 patients without postoperative infection were randomly selected among those who underwent ablation within three days as the control group. Clinical characteristics of both were analyzed by independent sample T-test and chi-square test. The recurrence-free survival and overall survival were compared between patients with and without infection complications by Kaplan-Meier method and COX survival analysis. Subgroup analyses of mild and severe infections were conducted to further explore the infection-related situation.

Results: Between mild and severe infection groups, there were statistically significant differences in infection position (P=0.043), positive rate of body fluid culture (P=0.002), the proportion of catheter drainage (P=0.017), use of advanced antibiotics (P=0.006) and outcome (P=0.00). Kaplan-Meier survival analysis revealed that postoperative infection was significantly correlated with tumor recurrence (P=0.028) and severe infection was significantly associated with overall survival (P=0.049). The cox model showed that postoperative infection was an independent variable of RFS deterioration (HR=1.745; 95% CI=1.054-2.891; P=0.031).

Conclusion: Postoperative infection among patients receiving thermal ablation adversely affected tumor progression. Empirical antibiotics and catheterization to reduce pressure inside the lesion should be utilized to minimize symptoms in patients with postoperative infection.

Abstract Submission No. 101625

The facts of ablation for liver cancer in patients aged ninety and above in our hospital.

Maki Tobarı1, Takuya Watanabe1, Hisafumi Yamagata1, Hiroaki Nagamatsu1, Hitoshi Maruyama1, Shuichiro Shiina1
1Department of Gastroenterology, Juntendo University School of Medicine Tokyo Japan

Purpose: In the context of Japan’s super-aging society, characterized by a growing population of very elderly individuals, this study investigates the safety and challenges associated with liver cancer ablation in patients aged 90 and above.

Methods: The subjects were 28 patients aged 90 and above who underwent radiofrequency or microwave ablation for liver cancer at our hospital from 2017 to 2023. We evaluate the characteristics of them.

Results: The cohort consisted of 13 females and 15 males, median age 91 (90-96), 25 HCC and 3 metastatic liver cancer, mean number of treatments 1.8 times. Pretreatment performance status was 0-1, 23, 2:5. Three patients had dementia. Prognosis was 11 survival, 6 death(liver-related death;1, other diseases;2, unknown;3), 11 discontinuation. Because some patients received multiple ablations, total ablations were 51. Evaluation in 51 cases from here. The mean number of ablated tumors:1.65, median diameter:16mm, RFA/MWA:21/30. All patients treated under sedation with midazolam (median 3mg). Poor awakening was observed in 9. Thirteen patients deviated clinical path(complications;3, additional ablation;2, decreased ADL;2, develop other disease;4). Three treatment-related complications occurred (hemothorax, liver abscess, portal vein thrombus).

Discussion: Patients aged over 90 who received ablation had good PS and liver function. A relatively large number of patients had poor arousal despite the use of low-dose sedatives, deviated from the clinical path due to decline in ADLs or development of other disease, or had difficulty attending the hospital. Complications were observed in 5.8%, but no serious complications were observed.

Conclusion: It became clear that ablation could be performed safely even in very elderly patients.

A Novel Ultrasound Modality to Monitor and Visualize Ablation Area based on Real-time imaging

1Techsomed Medical Technologies Ltd. Rehovot Israel, 2Department of Clinical Laboratory Medicine, Graduate School of Medicine, The University of TokyoThe University of Tokyo Tokyo Japan, 3Department of Gastroenterology, Graduate School of Medicine, The University of Tokyo Tokyo Japan, 4Department of Radiology, The University of Tokyo Tokyo Japan

Objective: Image-guided radiofrequency ablation is a well-established treatment for hepatocellular carcinoma. This study aimed to evaluate the predictive accuracy of BioTrace, a novel software utilizing B-mode ultrasound to classify the local changes in tissue viability in real-time, during liver ablation procedure.

Methods: The software provides an estimation of the ablation zone immediately post ablation (BioTrace Map) that correlates to the ablation zone as visualized in a 24-hour post-procedure (T=24) CECT scan. A comparison was carried out between the BioTrace Map based on B-mode ultrasound to that annotated by radiologists using contrast-enhanced CECT 24-hours after treatment, which is considered as the Gold Standard, for a total of 20 liver tumors. This comparison utilized the Dice Coefficient, Sensitivity, and Precision metrics.

Results: The median Dice Coefficient, Sensitivity, and Precision between BioTrace Map and the ablation zone visualized on T=24 CECT reached 90.3±2.2%, 90.3±4.5% and 90.1±4.4%, respectively. The intra-rater correlation presented excellent agreement between the findings of BioTrace and the radiologists regarding the volume size (0.98). Bland-Altman plot showed no evidence of systematic or proportional biases.

Conclusion: BioTrace used to visualize the ablated area reproduced the true ablated area as effectively as that by radiologists using post-operative CT. This system could ensure safe and effective ablation procedures in the future. Meaning, the software can accurately predict the ablation zone as would be visualized on T=24 CECT, based on real-time ultrasound imaging, and provide physicians with adjunctive...
information regarding the final ablation zone size and shape, as part of their overall clinical assessment.

Abstract Submission No. 101204

Novel real-time ultrasound-based software for ablation zone prediction following liver MWA

Yossi Abu1, Shuichiro Shiina2, Hitoshi Maruyama2, Maki Tobari2, Yuko Hijioka2, Hiroaki Nagamatsu2

1Techsomed Medical Technologies Rehovot Israel, 2Department of Gastroenterological Imaging and Interventional Oncology, Juntendo University Tokyo Japan

Objective: This study aimed to demonstrate the effectiveness of BioTrace, an algorithm-based imaging software, in estimating the ablation zone in liver MWA procedures using real-time ultrasound. The software provides an estimation of the ablation on the procedure day that shows a high level of agreement with the results of a CECT scan acquired 24 hours post-ablation.

Methods: We conducted a prospective single-arm trial on tumors undergoing ultrasound-monitored MWA with a single antenna. A CECT scan was obtained for each patient the day post-ablation (24h±4h, or T=24). The software produced a 2D BioTrace map (BTM) based on the ultrasound’s field of view along the needle plane. The BTM results were then compared to the T=24 CECT segmented ablation zone in the oblique plane corresponding to the ultrasound plane. This comparison utilized the Dice Coefficient, Sensitivity, and Precision metrics.

Results: The average Dice Coefficient between the BTM and T=24 CECT ablation zone was 89.3% (STD 2.9%), indicating a strong correlation between the two areas. The averaged Sensitivity and Precision values were 85.5% (STD 6.6%) and 94.1% (STD 5.7%), respectively. These results underscore BTM’s capability to accurately detect the ablation zone based on real-time ultrasound imaging during the procedure.

Conclusions: The BioTrace is effective in providing a close estimation of the ablation area as will be seen on the T=24 CECT, based on real-time ultrasound imaging thus can provide physicians with adjunctive information regarding the final ablation zone size and shape, allowing more accurate understanding of the ablation outcomes on procedure day.

Resection vs. RFA in Small and Large HCC: A Meta Analysis of Randomized Controlled Trial

Maria Teresa1, Refael Alfa Budiman1, Rino Alvani Gani1

1Hepatobiliary Division, Cipto Mangunkusumo General Hospital, Faculty of Medicine, Universitas Indonesia Jakarta Indonesia

BACKGROUND: While Radiofrequency Ablation (RFA) is often applied for nodules under 3 cm, some studies have demonstrated a favorable tumor response for larger nodules. This study aims to compare the efficacy of RFA and resection in HCC patients, considering nodule size with a cutoff at 3 cm.

METHOD: Using the PRISMA guidelines, comprehensive search was performed on seven databases. Small nodule was defined as ≤ 3 cm and large nodule as > 3 cm. All eligible studies were assessed using Cochrane RoB 2 for RCT. The pooled effect sizes were calculated using DerSimonian-Laird random-effects model and heterogeneity was investigated using Cochran’s Q test. Fixed-effect model was used and meta analysis was conducted using RevMan 5.4 software.

RESULT: A total of 5 studies, including 1046 patients were eligible for analysis. Overall survival and recurrence free survival in RFA and resection group were not statistically significant with hazard ratio (HR): 0.99; 95% CI 0.83, 1.19; p=0.96; I²=0% and HR: 1.07; 95% CI 0.93, 1.23; p=0.34; I²=0%, respectively. Subgroup analysis by nodule size also yielded similar findings. RFA and resection group also had similar recurrence rate with odds ratio (OR): 1.13; 95% CI 0.85, 1.49; p=0.41; I²=0%. Analysis of extrahepatic and intrahepatic recurrence found no significant difference between RFA and resection group.

CONCLUSION: In small or large nodule HCC, the efficacy of RFA and resection is similar. Additional considerations may be taken into account when choosing between RFA or resection in such condition.

KEYWORD: RFA; resection; HCC; small nodule; large nodule

Introduction of a safe device “Gangi-HydroGuard” for artificial pleural effusion and ascites in RFA

Takuto Yoshioka1, Hidea Mori1, Yuki Yamamoto1, Miho Hirai1, Gaku Okuno1, Iori Yagura1, Shohei Nakamori2, Taishi Matsumura1, Takashi Tamada1, Naoki Kanda1

1Takatsuki Red Cross Hospital Takatsuki Japan

Recently, SURF trial from Japan showed the efficacy of radiofrequency ablation (RFA) for 3 or less hepatocellular carcinomas (HCC) under 3cm equivalent to surgery. For a safe and secure RFA, artificial pleural effusion and ascites are effective, when HCC is located in the surface of liver or is adjacent to other organs. We report the features of a coaxial needle with spring loaded blunt tip stylet “Gangi-HydroGuard” and show our earlier HCC cases using this device.

We analyzed the success rate, adverse events, and recurrent rate in early 10 HCC cases from July 2021 when we introduced the procedure of artificial pleural effusion and ascites to Takatsuki Red Cross Hospital.

Six males and 4 female of median age 84 (48-87) were included. First, artificial pleural effusion was performed for 7 HCCs with average size 21.9mm (7-31) located in S8 or S5. Second, artificial ascites was performed for 3 HCCs with average size 23.7mm (16-35) located in S3 or S5. We succeeded the procedures in all cases, however in 1 case, the first puncture was difficult in penetrating peritoneum and the second puncture was succeeded. No adverse events were occurred except for 1 case with a temporary decrease of the oxygen concentration, after artificial pleural effusion was performed. We experienced a recurrence of HCC in 1 case of size 35mm located in S3 with the artificial pleural effusion.

We could safely introduced the procedures of artificial pleural effusion and ascites in RFA with “Gangi-HydroGuard”.

1Division of Gastroenterological and General Surgery, Department of Surgery, School of Medicine, Showa University, Tokyo, Japan

Background: Laparoscopic deroofing (LD) has recently been considered a standard procedure for giant liver cyst, although it has the risk of postoperative bile leakage. The line of resection is ambiguous and there is a risk of biliary fistula if it enters the liver parenchyma. To determine the line of resection, we performed Indocyanine green (ICG) fluorescence-guided LD.

Methods: This was a retrospective study including 29 patients who underwent LD between April 2013 and October 2023 at our institute. These enrolled patients were divided into an ICG group (n = 7) and a white light group (n = 22).

Results: There were no significant differences among age, gender, maximum tumor size, estimated blood loss and postoperative hospital stay. There was one case of postoperative bile leakage in the ICG group, though there was no significant difference.

There were two cases to detect the bile leakage in real time at ICG group. Fluorescent bile juice was detected from the resection line intraoperatively and we could suture of the area and fix them. These cases were discharged without complications.

Conclusion: ICG fluorescence-guided LD may offer clinical benefits to avoid bile duct injury. It is useful in determining the line of dissection and can also avoid the bile leakage.

Indocyanine green fluorescence-guided laparoscopic deroofing for giant hepatic cyst

Sadahito Iseki1, Takeshi Aoki1, Hideki Shibata1, Tatsuya Yamazaki1, Kazuhiko Saito1, Marie Uchida1, Takahiro Hirai1, Kodai Tomioka1, Yoshihiko Tashiro1, Hiromi Date1, Ryohi Watanabe1, Kazuhiko Matsuda1, Tomokazu Kusano1, Kimiyasu Yamazaki1, Makoto Watanabe1

1Division of Gastroenterological and General Surgery, Department of Surgery, School of Medicine, Showa University, Tokyo, Japan

Background: The advancement of cancer genomic medicine has emphasized the importance of liver tumor biopsy and clinical sequencing. Tissue collection devices are broadly classified into aspiration-biopsy and cutting type, and the cutting type is further divided into sidecut-biopsy needle and full-core biopsy needle. Recently, the usefulness of the full-core biopsy needle has been reported, but there have been few reports comparing the clinical sequence with each method. In the present study, we retrospectively evaluated the eligibility of various testing devices and the clinical sequence.

Methods: We included 20 liver tumor biopsies submitted to clinical sequence among the liver tumor biopsies performed at our institution from 2019 to 2023. The clinical sequence eligibility of the specimens collected and the safety of the procedure were reviewed.

Results: The median age of patients was 68 years, with 55% being male. Biopsies were performed using aspiration-biopsy needles (Surecut®18G) in 4 cases, sidecut-biopsy needles (Monopty®18G) in 7 cases, and full-core biopsy needles (CorvoCut®18G) in 9 cases. Ineligibility for clinical sequencing was observed in two cases using aspiration-needles and one with a sidecut-needle. In contrast, specimens from all full-core needle biopsies were eligible. No complications were reported in any of the biopsy procedures. Although the cutting type biopsy needles tended to require fewer biopsies for adequate tissue collection, this difference was not statistically significant. No needle type showed complications requiring treatment.

Conclusion: The full-core biopsy needle provided a clinical sequence-eligible tissue sample that was comparable to or better than existing methods for liver tumor biopsies.

Accessing and Predicting Liver Function by Elastography: 1-year Follow-up in HCC Ablation Patients

Jiayao Huang1, Xiaoyan Xie1, Manxia Lin1

1Sun Yat-sen First Affiliated Hospital Guangzhou China

Aim: The present study aims to investigate the changes in liver function and liver stiffness (LS) measured by two-dimensional shear wave elastography (2D-SWE) before and after ablation in patients with hepatocellular carcinoma (HCC), and to explore the feasibility of using LS before and after ablation as a means to assess and predict liver function, gaining a better understanding of the impact of ablation on liver function and LS’s potential as a diagnostic tool for HCC patients.

Material and Methods: From March 2022 to December 2023, 101 patients with treatment-naïve HCC and undergoing ablation were retrospectively enrolled and followed-up for one year. Data including LS and indicators of liver function were collected at pre-operative period and post-operative 1 month, 3 months, 6 months, and 12 months, respectively. Statistical analysis was conducted to explore the correlation between LS and liver function during the follow-up.
Results: Among the enrolled patients, 69 (68.3%) underwent percutaneous radiofrequency ablation, 23 (22.8%) underwent percutaneous microwave ablation, and 9 (8.9%) cases underwent other methods of ablation (such as laparoscopic ablation). Using pre-operative LS as the baseline, paired t-test showed that LS slightly increased at 1 month post-operatively and then decreased (all p<0.050). This trend was similar to the changes in liver function before and after ablation. There was a significant correlation between pre-operative LS and liver function (represented by Child-Pugh and ALBI scores) at pre-operative period and post-operative 1, 3, 6, and 12 months (all p<0.050). Additionally, LS at 1, 3, and 6 months post-operatively was significantly correlated with the immediate post-operative liver function (all p<0.050).

Conclusion: LS is expected to become a powerful tool for assessing and predicting liver function in HCC ablation patients, which could help alleviate the burden of follow-up examinations to some extent.

Safety and efficacy of MVA of multiple lesions in multiple Lung Metastasis of Colorectal Cancer
Rong Ding1, Jinfeng Bai2, Bohan Song1
1Yunnan Cancer Hospital Kunming China

Objective: This study aims to retrospectively analyze the safety and effectiveness of microwave ablation (MWA) in treating multiple lung metastases from colorectal cancer.

Approaches: A retrospective analysis was conducted on the clinical data of patients with colorectal cancer multiple lung metastases who underwent MWA treatment at Yunnan Cancer Hospital from January 2020 to December 2022. The main objective of the study was to determine the median overall survival (mOS), while additional objectives included assessing the median progression-free survival (mPFS), technical success rate, and complication rate. The statistical analysis involved the utilization of the log-rank test and the Cox proportional risk regression model.

Outcomes: There were 50 patients with numerous lung metastases from colorectal cancer who received MWA treatments. The overall mOS time for all patients was 26 months, with a 95% confidence interval (CI) ranging from 20.93 to 31.10 months. Similarly, the mPFS time was 23 months, with a 95% CI ranging from 16.76 to 29.24 months. Furthermore, the group that underwent single MWA showed a superior mOS compared to the group that underwent fractionated MWA. The hazard ratio (HR) was 4.756, with a 95% confidence interval (CI) of 1.076 to 21.033, and a p-value of 0.04.

Conclusion: MWA is a secure and efficient method for treating numerous metastases of colorectal cancer in the lungs. For one side of the lung, numerous metastases can be treated with a single, divided ablation procedure that targets many points. Further investigation is required to determine the efficacy of ablating numerous metastases in both lungs while ensuring safety.

THE ROLE OF CARTO IN PORTAL HYPERTENSION WITH RECURRENT UPPER GI BLEEDING FROM LARGE GASTRIC VARICES
Mateo III Te1, Mara Teresa T. Panlilio2
1UUniversity of the Philippines - Philippine General Hospital Manila Philippines, 2University of the Philippines - Philippine General Hospital Manila Philippines

A 26-year-old, female with no co morbidities and unremarkable perinatal, personal, family, and OB Gyne history presented with melena associated with body weakness. She was hospitalized with a hemoglobin of 3 g/dL and was transfused with 7 units packed RBC. Emergency upper endoscopy revealed small esophageal varices and large gastroesophageal varices (GOV2) which was treated with injection of histoacryl glue to the gastric varices. After the bleeding was controlled, she was started on beta blockers and was advised further work up. Work up revealed non-reactive hepatitis B and C profile and a considderation of portal thrombosis and portal cavernoma on CT scan. Hematology service was on board to rule out hematologic causes of portal thrombosis. Work up were all unremarkable for ANA, anti-DsDNA, APAS panel, clotting factor II and V PCR, and JAK 2 mutation by PCR. On the following months, the patient had multiple recurrences of melena and hematochezia requiring massive blood transfusions and emergency endoscopic glue injections. A multi-disciplinary team meeting consisting of hepatology, interventional gastroenterology, hepatobiliary surgery, and interventional radiology was held to discuss the best acceptable management for the patient. The consensus of the meeting was to do a Coil-Assisted Retrograde Transvenous Obliteration (CARTO) to control the portal hypertension and subsequently the bleeding varices. The patient consented to the plan offered by the team and underwent CARTO successfully. On follow up; there was no longer recurrence of GI bleeding and laboratories are within normal. The patient was advised for surveillance endoscopy and liver function tests monitoring.

Efficacy of EmprintTM Ablation System for Perivascular Hepatocellular Carcinoma
Xuan Yu1, Kai Li1
1The Third Affiliated Hospital of Sun Yat-sen University Guangzhou China

Background: Conventional microwave ablation encounters major challenges with unpredictable and inconsistent ablation zones, particularly in dynamic tissue environment near intrahepatic blood vessels. The EmprintTM system with thermosphere technology offers a potential solution to this issue. This retrospective study assesses the effectiveness of the EmprintTM ablation system in treating hepatocellular carcinoma (HCC), emphasizing outcome comparisons between perivascular and non-perivascular cases.

Methods: From January 2019 to September 2022, 135 HCC patients underwent Emprint™ microwave ablation were enrolled. Cases were categorized into perivascular (N=109) and non-perivascular (N=26) groups based on tumor proximity to intrahepatic vascular. Propensity score matching (PSM) was then applied to balance the baseline characteristics between two groups. The 1-year post-ablation intrahepatic tumor recurrence rates and major complications rates were subsequently analyzed.

Results: The 1-year post-ablation intrahepatic tumor recurrence rates were lower in the perivascular group compared to non-perivascular cases in the overall cohort (7.7% vs. 15.6%, P=0.529) and in the PSM cohorts (8.7% vs. 14.8%, P=0.714). The major complication rate in the non-perivascular group was [3.7% (4/109)] in the total cohort and [5.6% (3/54)] in the PSM cohort. No complications were observed in the perivascular group.

Conclusions: The Emprint™ microwave ablation system demonstrated compelling efficacy with reduced tumor recurrence and
complication rates in the management of the previously challenging perivascular HCC lesions. These encouraging results position the Emprint™ system as a promising and viable treatment option for patient with perivascular HCC.

AI Based Tumor Progression Prediction following Hepatocellular Carcinoma Ablation

Tom Edlund1, Masaya Sato2,3, Ryosuke Tateishi3, Jiro Sato4, Takeyuki Watadani5, Taijiro Wake1, Ryo Nakagomi3, Takuma Nakatsuka1, Tatsuya Minami2, Koji Uchino5, Kenichiro Enoku1, Chao-Chun Chuang3, Yu-Chia Su1

1Department of Clinical Laboratory Medicine, Graduate School of Medicine, The University of Tokyo Tokyo Japan, 2Department of Gastroenterology, Graduate School of Medicine, The University of Tokyo Tokyo Japan, 3Sheba Medical Center Ramat Gan Israel Purposes: to explore new tumor progression predictors that are more accurate and robust than minimal ablative margin (MAM) and to evaluate a novel, AI based, fully automatic, 3D software for tumor coverage assessment and tumor progression prediction.

Materials & Methods: Single-center retrospective single-arm study. 216 patients underwent radiofrequency ablation to treat HCC. Tumor progression was defined as residual unablated tumor or local tumor progression (LTP), which was based on a CECT scan 24 hours post procedure. The study assessed a novel fully automatic 3D software for ablation outcome assessment and the LTP predictive power of a novel metric named weighted relative ablated target (WRAT). The LTP predictors were compared using the area under curve of the receiver operating characteristic curve.

Results: The area under curve of the receiver operating characteristic curve results for the evaluated LTP predictors: human expert MAM, fully automated MAM and fully automated WRAT are 70.9%, 78.4% and 81.7% respectively.

Conclusions: The study results indicate that our AI based fully automatic SW using deformable registration is more effective in predicting fully automated MAM and fully automated WRAT are 70.9%, 78.4% and 81.7% respectively.

IMPACT OF SAMPLE VARIABILITY OF LIVER NEEDLE BIOPSIES ON FIBROSIS ASSESSMENT

Yayun Ren1, Kutbuddin Akbary1, Elaine Chng1, Dean Tai1, Jonathan A. Fallowsfield2, Timothy J. Kendall2, Nikolai V. Naoumov3, David E. Kleiner4, Arun J. Sanyal5

1HistolIndex Pte Ltd Singapore Singapore, 2Centre for Inflammation Research, University of Edinburgh Edinburgh United Kingdom, 3London United Kingdom, 4Laboratory of Pathology; Center for Cancer Research, National Cancer Institute, National Institutes of Health Bethesda United States, 5Stravitz-Sanyal Institute of Liver Disease and Metabolic Health, Virginia Commonwealth University School of Medicine Richmond United States

Introduction: Variability in fibrosis assessment due to needle positioning in liver biopsy is currently under-evaluated. This study investigates the influence of positional and rotational variability on the accuracy of fibrosis assessment using Second Harmonic Generation/Two Photon Excitation (SHG/TPE) microscopy and artificial intelligence (AI)-based analysis.

Methods: 100 liver resection and explant samples, covering NAS-CRN stages F0-F4, were evaluated by SHG/TPE microscopy. The virtual needle biopsies (width 0.9mm and length 15mm) were taken from each sample. Rotational and positional variability introduced through rotation angles at 20⁰ intervals and varying tissue positions within samples respectively. qFibrosis assessment was performed for all virtual needle biopsies and the whole tissues. The analysis employed linear weighted kappa (LWK), Obuchowski-index (multinomial version of AUROC), Spearman’s correlation to evaluate accuracy and agreement of assessments.

Results: The Obuchowski-index of qFibrosis continuous value was 0.92-0.95 for rotation variability, 0.90-0.95 for position variability. There was substantial agreement between qFibrosis stage and pathologist readings (LWK=0.70-0.81 rotation variability,
LWK=0.68-0.79 position variability). Correlation of total fibrosis area between virtual biopsies and whole tissues was strong for rotation variability (r-value=0.85-0.89) and position variability (0.82-0.92). Fibrosis area in portal tract, peri-portal, and zone 2 regions exhibited higher correlation (mean r-value=0.87) compared to central vein and peri-central regions (mean r-value=0.55) between virtual biopsies and whole tissues.

Conclusions: Positional and rotational variabilities had no significant impact on liver fibrosis assessment using qFibrosis. The strong correlation between virtual biopsies and whole tissue fibrosis evaluation using SHG/TPE microscopy further support qFibrosis as a reliable method for quantitative fibrosis assessment.

Understanding early stage-fibrosis in KBI-NASH non-human primate model using AI digital pathology

Desiree Abdurrachim¹, Charlene Z L Ong¹, Ashmita Saigal², Yongqi Zhou¹, Muhammad R A Yahya¹, Christopher Hendra¹, Samata Kakkad², Radha Krishnan³, Annaswamy Raji³, Thomas Forest⁴, Shubing Wang⁵, Richard Baumgartner⁶, Chih-Liang Chiu⁷, Saswata Talukdar⁷, Asad A A Ali³

¹MSD Singapore Singapore, ²Merck & Co., Inc., South San Francisco, CA USA, ³MSD London UK, ⁴Merck & Co., Inc., Rahway, NJ USA, ⁵Merck & Co., Inc., West Point, PA USA

Background: Liver biopsy specimens contain abundant information on liver microenvironment, which may offer novel biological insights into disease progression/regression. Here, we investigated changes in liver microenvironment features during early development of NASH.

Methods: We evaluated 11 paired liver biopsies from NASH-NHP model developed by Kunming Biomed International (KBI), at >2 years after high-fat diet (baseline) and at the following 12 weeks, using Histolindex AI digital pathology platform, which combines a novel imaging technique based on Second Harmonic Generation/Two-Photon Excitation Fluorescence and a proprietary image analysis to quantify zone-specific fibrosis and steatosis features.

Results: At baseline, most animals exhibited steatosis (median of 3 pathologist’s grade S0: 1/11, S1: 3/11, S2: 4/11, S3: 3/11), without pathological fibrosis (F0: 10/11, F1: 1/11), which progressed at week 12 (F0 to F1: 3/11, F0 to F2: 6/11). The progression was characterized by a high PS steatosis activity, with increased macrosteatosis (P=0.04 vs. baseline) and PS fibrosis (P=0.05 for most features of aggregated fibrosis, vs. baseline). Increased steatosis-colocalized fibrosis was also observed (P=0.03 vs. baseline), which suggests a metabolic contribution to the early-stage fibrosis in this model. Unsupervised clustering revealed 3 patterns of disease progression: (1) worsened PS fibrosis with mildly increased PT, (2) mildly increased PS fibrosis, (3) markedly increased CV fibrosis.

Conclusion: Our study demonstrated the metabolic relevance of KBI-NASH-NHP model and the utility of AI digital pathology in studying changes during the early-stage fibrosis. Future work includes validation in a larger dataset to elucidate key differentiators for progression at early-stage and late-stage fibrosis.

Assessment of resmetirom-mediated reductions in liver volume on fibrosis changes MAESTRO-NASH trial

Stephen A. Harrison¹, Rebecca Taub¹, Dominic F. Labriola², Elaine Chng³, Yayun Ren³, Dean Tai¹

¹Pinnacle Research, San Antonio Texas USA, ²Madrigal Pharmaceuticals Pennsylvania USA, ³Histoindex Pte. Ltd. Singapore Singapore

Background: MAESTRO-NASH, a phase 3 registrational non-cirrhotic NASH clinical trial achieved NASH resolution and fibrosis reduction endpoints on liver biopsy at 52 weeks. As an exploratory endpoint, artificial intelligence slide reading technologies were employed to measure the effect on fibrosis in serial liver biopsy using both continuous and quantitative scoring.

Method: Fibrosis was estimated as a continuous and categorical variable using second harmonic generation (SHG) (qFibrosis)/two-photon excited fluorescence of 768 paired biopsy samples from MAESTRO-NASH. A separate unstained slide was analyzed for qFibrosis [normalized by tissue area and then corrected for qSteatosis (tissue area-steatosis area)].

Results: Based on a continuous qSteatosis score, the % change from baseline in steatosis was 80 mg, -36%; 100 mg, -46%; placebo, -10%, p<0.0001 for both doses, the continuous change from baseline in corrected qFibrosis score was 80 mg, -22%; 100 mg, -20%; placebo, 3%, p<0.0001 for both. Based on categorical change in qFibrosis score, there was a significant improvement in fibrosis stage (1- or 2-stage improvement) at 80 and 100 mg relative to placebo, and less worsening of fibrosis in the resmetirom treatment groups compared with placebo (Table). The percentage showing improvement in qFibrosis (>1-stage) was higher than scored by pathologists and identified 90% of resmetirom responders.

Conclusion: Measurements of fibrosis change using qFibrosis on either a continuous or categorical scale demonstrated a clear improvement and less worsening in fibrosis in resmetirom treated NASH patients as compared with placebo after 52 weeks of treatment.

Abstract Submission No. 100985
O-0462

Artificial intelligence to measure fibrosis change on liver biopsy in the MAESTRO-NASH phase 3 trial

Stephen A. Harrison¹, Rebecca Taub², Dominic F. Labriola², Mustafa R. Bashir³, Elaine Chng³, Yayun Ren³, Dean Tai⁴

¹Pinnacle Research, San Antonio Texas USA, ²Madrigal Pharmaceuticals Pennsylvania USA, ³Center for Advanced Magnetic Resonance Development, Departments of Radiology and Medicine (Gastroenterology), Duke University Durham, North Carolina USA, ⁴Histoindex Pte. Ltd. Singapore Singapore

Background: MAESTRO-NASH, a phase 3 registrational non-cirrhotic NASH clinical trial achieved NASH resolution and fibrosis reduction endpoints on liver biopsy at 52 weeks, with resmetirom-treated patients achieving significant improvements in liver volume. In this analysis, we explored the effect of liver volume reduction on AI-based fibrosis assessment at the parameter-level.

Method: Quantified collagen parameters in the liver lobule regions were obtained from AI measurements of separate unstained slides using SHG/TPEF microscopy. Using liver volume from serial MRIs at baseline and week52 for 634 patients, a coefficient was applied to the AI-based collagen parameters to account for the liver volume reduction to analyse the impact on patients showing more than 10% relative reduction of collagen parameters.

Results: Both resmetirom doses revealed a larger percentage of patients showing more than 10% relative reduction of collagen parameters at the portal, peri-portal and zone 2 regions (Fig. A) (8 to 24%, p<0.01) compared to placebo. After applying the coefficient to account
for liver volume reduction with resmetirom treatment (Fig. B), the percentage of resmetirom-treated patients with more than 10% relative reduction of collagen parameters increased across all zones, notably at the portal, peri-portal and zone 2 regions (26 to 36%, p<0.01), and at the peri-central region (11 to 14%, p<0.05) in both resmetirom doses versus placebo.

**Conclusion:** Quantification of changes in NASH fibrosis are impacted by therapeutic interventions that alter liver volume. Correcting for liver volume reveals the greater impact of resmetirom with more pronounced regression patterns at the collagen parameter-level compared to placebo.

**The Deep Learning of Ultrasonography in Automatic Detection and Diagnosis of Liver Tumors.**

Chih-Horng Wu1,3, Jin-Chuan Sheu2,3, Hsiao-Ching Nien2,3
1National Taiwan University Hospital Taipei Taiwan, 2Good Liver Foundation Taipei Taiwan, 3National Taiwan University Taipei Taiwan

**Background:** Ultrasound (US) is the most common screening tool for hepatocellular carcinoma (HCC). However, the diagnostic performance of ultrasound is highly operator-dependent. We aimed to develop deep-learning models to detect and diagnose hepatic lesions automatically.

**Materials and methods:** We enrolled patients diagnosed with hepatic tumors by the abdominal US from January 2002 to December 2020 in a retrospective cohort with the diagnosis of malignant (HCC, cholangiocarcinoma, and metastasis) and benign lesions (hepatic cysts, hemangiomas, focal fatty sparing, focal nodular hyperplasia, and other benign findings). 1,576 patients with 4,600 images, and 6,001 lesions were analyzed. Deep learning models included ResNet50, Xception, Inception Resnet V2, and EfficientNet-B5 for non-real-time classification and YOLO v4 for lesion automatic detection and diagnosis.

**Results:** A total of 1,576 patients separated into 1,061 in training, 373 in validation and 142 in testing set. The AUC for ResNet50, Xception, Inception Resnet V2, and EfficientNet-B5 were 0.88, 0.89, 0.88, and 0.90. After the optimal threshold was selected in the base model of EfficientNet-B5, the accuracy, recall (sensitivity), precision and F1 score for the validation and testing dataset were 0.836, 0.837, 0.626, 0.716 and 0.699, 0.699, 0.289, 0.408. The mean Average Precision score to differentiate between malignant and benign lesions for YOLO v4 was 0.5441.

**Conclusion:** Our study provides the deep learning model with high accuracy in ultrasound differentiation and diagnosis of benign and malignant lesions. Furthermore, the Yolo-v4 model also demonstrates high performance in real-time automatic detection and diagnosis.

**Insights into Post-Hepatectomy Liver Failure Prediction with Interpretable Deep Learning Framework**

Xian Zhong1, Manxia Lin1, Xiaoyan Xie1
1The First Affiliated Hospital of Sun Yat-sen University Guangzhou China

**Purpose:** To develop an interpretable framework for understanding the predictions of the deep learning model for Post-hepatectomy liver failure (PHLF).

**Material and Methods:** A total of 345 consecutive patients were enrolled. We employed a variational autoencoder (VAE) to transform two-dimensional shear wave elastography (2D-SWE) images into latent space encodings, which were then used to train a multi-layer perceptron (VAE_MLP_SWE) model. Clinical variables were incorporated into the latent space to train a VAE_MLP_SWE_clinical model. Counterfactual explanations were generated by latent space traversal of the VAE to observe the change in 2D-SWE images with predicted probability. Layerwise relevance propagation (LRP) was used for global and local explainability with respect to SWE image and clinical variables.

**Results:** The VAE-MLP_SWE model showed a higher AUC (0.759) than the Densenet121 (0.745) and Resnet18 (0.703) models during five-fold cross-validation. The VAE_MLP_SWE clinical model demonstrated a significant improvement (p<0.05) in AUC (0.828) compared to clinical indices such as Child-Pugh score, ALBI score, and MELD score (AUC 0.529-0.684) on the test set. Qualitative analysis of counterfactual explanations generated for both VAE_MLP_SWE and VAE_MLP_SWE clinical revealed that clinically relevant semantic features were used for prediction. Quantitative evaluation of counterfactuals with different predicted probabilities revealed a consistent correlation with liver stiffness measurement. The global LRP analysis identified SWE image, future liver remnant volume (FLR), and albumin (ALB) as the most important features for PHLF prediction.

**Conclusion:** The proposed VAE-MLP framework offers insights into the decision-making mechanism of the deep learning model for prediction of PHLF with high accuracy.

**Finding Undiagnosed Hepatitis C Using a Machine Learning Algorithm: An Australian Pilot**

Linda Chen1, Heshaam Mir2, David Baker3, Shelley Kerr4, Jacqueline Richmond5, Rehan Ali5, Brittany Schoening5, John Rigg6, Chris Ng7, Bria Fergus8, Bruce Kreteler1
1Gilead Sciences Foster City United States, 2Gilead Sciences Melbourne Australia, 3East Sydney Doctors Sydney Australia, 4Australasian Society of HIV, Viral Hepatitis and Sexual Health Medicine Sydney Australia, 5Public Health, Burnet Institute Melbourne Australia, 6Predictive Analytics, Real World Solutions, IQVIA London UK, 7Real World Solutions, IQVIA Sydney Australia, 8Campbell University College of Pharmacy Buies Creek United States

**Background:** To validate an artificial intelligence (AI) algorithm capable of identifying patients in an Australian population who are undiagnosed with Hepatitis C Virus (HCV)

**Methods:** This study analyzed retrospective data from 371 Australian general practices’ electronic medical records (EMR) between 2017 and 2022, comprising 19 million patients. A high-performance machine learning model (XGBoost) was trained on deidentified clinical data to find undiagnosed HCV cases by using clinical predictors associated with HCV infection, then validated on a separate dataset. Algorithm performance was evaluated based on recall and fold improvement compared to standard screening methods recommended by the World Health Organization (WHO).

**Results:** The dataset contained 9 million deidentified patients aged >18 years who exhibited evidence of attending healthcare within a 24-month period. Of these, 2,515 patients were identified as HCV-positive. Table 1 shows the model performance compared to universal screening
and birth cohort screening. At 5% recall (the population with the highest predicted risk), the algorithm demonstrated a 116.5-fold improvement over universal screening, which is comparable to the performance of a previous US-based algorithm. As a point of comparison, the birth cohort (i.e., WHO recommendation to screen patients born between 1946-64) demonstrated a 2.2-fold improvement over universal screening. AUROC of the model was 0.735. Top predictors used by the model included age, gender, chronic liver disease, anti-anxiety medications, analgesics, bilirubin, and alanine transaminase (ALT).

Conclusion: This study demonstrates that our validated machine learning algorithm can identify undiagnosed HCV patients in Australia, and can improve patient screening efficiency.

Predictive validation of GLIM criteria for mortality in patients with cirrhosis: a machine learning

gao Yue Guo1, Sun Chao1

1Tianjin Medical University General Hospital Tianjin China

Background: Recently, a novel framework designated as GLIM criteria has been proposed to harmonize malnutrition diagnosis across distinct populations and disease settings. From the standpoints of predictive, preventive and personalized medicine, we sought to validate the prognostic performance and refine the best combinations of phenotypic and etiologic GLIM criteria associated with long-term mortality in patients with decompensated cirrhosis.

Methods: This retrospective observational study enrolled decompensated hospitalized patients with cirrhosis. The GLIM phenotypic criteria comprised unconscious weight loss, low BMI and low SMI, while etiologic criteria entailed reduced food intake or assimilation, disease burden indicative of high MELD-based scores, aggravating Child-Pugh classification and inflammation indicative of high NLR. Fifty GLIM combinations were examined according to the sensitivity, specificity, negative/positive predictive values along with a machine learning algorithm (Random forest).

Results: The sample consisted of 219 patients with decompensated cirrhosis; 50.7% females; a median age of 63 years. The prevalence of malnutrition varied from 3.7% to 45.7%. Cox regression indicated that 38 combinations were significantly associated with 1-year all-cause mortality with hazard ratios (HRs):≥2. Notably, the HRs of SMI.MELD, BMI.MELD, BMI.MELD3.0 were as high as 4.832, 4.497, 4.335, respectively. Random forest algorithm unraveled that SMI.MELD performed best for prediction.

Conclusions: The majority of GLIM combinations was linked to inferior outcomes in the context of decompensated cirrhosis. Our findings shed light on the predictive diagnostics, targeted preventive and individualized treatment to counteract distinctive malnourished features among hospitalized cirrhosis, which may improve outcomes, symptoms and quality of life and correct nutritional status.

Artificial intelligence assisted navigation surgery in laparoscopic liver resection.

Yoshihiko Tashiro1, Takeshi Aoki1, Nao Kobayashi2, Kodai Tomioka3, Kazuhiko Saito4, Takahito Hirai5, Tatsuya Yamazaki1, Hideki Shibata1, Kazuhiro Matsuda1, Tomokazu Kusano1, Shodai Nagaishi1, Yukari Shinhoara1, Koji Nogaki1, Akira Fujimori1, Yuta Enami1

1Department of General and Gastroenterological Surgery, Showa University School of Medicine, Tokyo Japan, 22. Anaut Inc. Tokyo Japan

Background and Objective: Recently, the prediction of anatomical structures by artificial intelligence (AI) is expected to support surgeons as navigation tool. We reported AI system can recognize vascular structures during liver parenchymal transection. This preliminary study demonstrated whether AI technology become navigation tool in recognizing anatomical structures during LLR. Method: We used Surgical AI Eureka® (Anaut Inc., Tokyo, Japan) to recognize various anatomical structures and detect bleeding. We made AI recognize lose connective tissue during liver mobilization and vascular structures during liver transection, and we examined bleeding detection function.

Results: This AI model enabled to recognize these vascular structures of any size with high accuracy (IoU=0.33, Dice=0.44) and AI could distinguish glissions from hepatic veins. AI recognized lose connective tissue (IoU=0.56, Dice=0.60) during liver mobilization and dissection of hepatoduodenal ligament for safe dissection plane. Loose connective tissue was also recognized by AI in intractable cases of repeat liver resection and tumor invaded other organs. We could identify the bleeding point using bleeding detection function. AI exactly highlights anatomical structures without any visual disagreed in real time about 0.12 second.

Conclusion: This AI system is useful as navigation technology in laparoscopic liver surgery. Nobel navigation surgery using AI technology suggested the possibility to perform safer and more reliable liver surgery in near future.

Causal inference data analysis pipeline for identifying proteins within NAFLD/NASH sub-cohorts

Chamara K Liyanaarachchi Lekamalage1, Smita Sampath1, Luo Weiwei1, Charlene Z L Ong1, Pei Z Goh1, Ziwei Shu1, Asad Abu Bakar Ali1

1Quantitative Biosciences, MSD Singapore Singapore

Non-Alcoholic Fatty Liver Disease/Non-Alcoholic Steatohepatitis (NAFLD/NASH) is a highly prevalent heterogenous disease with several sub-cohorts. Herein, we propose a data analysis pipeline for identifying proteins within these sub-cohorts to gain insights into NAFLD/NASH. The pipeline consists of two algorithms: 1) LIMMA (Linear Models for Microarray) differential expression analysis to identify proteins that differentiate between the various sub-cohorts of NAFLD/NASH; 2) Causal inference to determine the causality of differentiating proteins identified in the previous step to the biomarker. The analysis is conducted using data from the UK Biobank (UKB) with subjects having olink proteomics data. The proposed pipeline is applied on 4 sub-cohorts of group of individuals with fatty liver disease: proteins differentiating the interaction between (i) elevated cT1 and PNPLA3 (rs738409)+ variant with high and low cT1, (iii) elevated cT1 and PNPLA3 (rs738409)+ variant, (ii) PNPLA3 (rs738409)+ variant with high and low cT1, (iii) elevated cT1 and PNPLA3 (rs738409)+ variant, (iv) elevated cT1 and PNPLA3 (rs738409)- variant. The results of the analysis provided insights into NAFLD/NASH progression for these four sub-cohorts: 1) perturbed glucose metabolism appears to primarily drive immune regulation and pro-inflammatory signaling, 2) proteins associated with inflammation (IL-6), lipid metabolism and cardiovascular function are upregulated, 3) innate...
immune response may play a role in the progression of NAFLD/NASH, 4) direct cytokine signaling and oxidative stress, which are likely associated with obesity (for example, visceral adipose tissue expansion), may contribute to the development of NAFLD/NASH. These insights help enhance our understanding of the underlying mechanisms of NAFLD/NASH progression.

Application of transformer model for capsule endoscopic gastric structure recognition
Qingyuan Li¹, Weijie Xie², Yusi Wang¹, Kaiwen Qin¹, Wei Yang², Side Liu¹
¹Nanfang Hospital, Southern Medical University Guangzhou China, ²Southern Medical University Guangzhou China

Background: Gastric structure recognition systems have become increasingly necessary for the complete and accurate diagnosis of gastric lesions in capsule endoscopy. Deep learning, especially using transformer models, has shown great potential in the recognition of GI images according to self-attention. This study aims to establish a precise label library of capsule endoscopy gastric structures to improve the clinical applicability of deep learning to endoscopic image recognition.

Methods: A total of 2433 WCE videos collected at our center between 2011 and 2021 were used to train a transformer-based AI model, while 118 additional WCE videos were used for validation. Fifteen upper gastrointestinal structures were selected for quantifying the examination quality. We also conducted a comparison of the classification performance between the AI model and endoscopists by the accuracy, sensitivity, specificity, and positive and negative predictive values.

Results: The transformer-based AI model reached a relatively high level of diagnostic accuracy in gastric structure recognition. Regarding the performance of identifying 15 upper gastrointestinal structures, the AI model achieved a macroaverage accuracy of 99.6% (95% CI, 99.5-99.7), a macroaverage sensitivity of 96.4% (95% CI, 95.3-97.5), and a macroaverage specificity of 99.8% (95% CI, 99.7-99.9) and achieved a high level of interobserver agreement with the expert endoscopists.

Conclusion: The transformer-based AI model can accurately evaluate the gastric structure information of capsule endoscopy with the same performance as that of expert endoscopists, which will provide tremendous help for doctors in making a diagnosis from a large number of images and improve the efficiency of examination.

Practical Clinical Uses of Chat GPT: What Hepatologists Should Know
Marco Distefano¹, Giuseppe Alaimo²
¹UOSD Hepatology ASP 8 Siracusa Italy Siracusa Italy, ²UOC Medicina Interna Licata Italia

Artificial Intelligence (AI), particularly through tools like Chat GPT, is transforming Clinical Hepatology by enhancing patient care and research. This integration is crucial as many hepatologists are unfamiliar with AI’s practical applications in their field. AI focuses on improving diagnostic accuracy, tailoring treatment plans, and efficiently managing patient data. Its role extends to interpreting complex diagnostic images, forecasting disease progression, and guiding liver transplant decisions. These advancements, however, come with ethical and practical challenges in implementation.

AI’s impact in hepatology is profound, improving diagnostics, therapy, and research. Advanced algorithms refine imaging interpretation, aiding in early detection and management of liver diseases. AI also streamlines processing vast amounts of data in Electronic Health Records (EHR), enhancing both care and research precision.

AI contributes significantly to risk prediction models, enabling more accurate forecasts of disease progression and treatment outcomes. This leads to more personalized patient care. AI is also instrumental in formulating individualized treatment plans and in decision support systems, essential for informed clinical decision-making in hepatology. Despite its benefits, AI integration in hepatology faces challenges like data privacy concerns, the need for diverse datasets, and algorithmic biases. Overcoming these challenges requires careful planning and training for effective AI integration into existing healthcare systems. In summary, AI, especially Chat GPT, represents a major leap in Clinical Hepatology. Its current applications have already enhanced diagnostic precision and patient care, yet its full potential in hepatology is still unfolding, contingent on addressing ongoing ethical and practical issues.

Predicting Lymph Node Metastasis of Hilar Cholangiocarcinoma Based on Deep Learning Radiomics
Baoxian Liu¹, Hui Shen¹
¹The First Affiliated Hospital of Sun yat-sen University Guangzhou China

Purpose: To explore the potential deep learning radiomic(DLR) models based on B-mode ultrasound(BUS) and contrast-enhanced ultrasound(CEUS) images in predicting preoperative lymph node metastasis(LNM) of hilar cholangiocarcinoma(HCCA).

Methods: 110 HCCA patients from two clinical centers were included, and divided into a primary cohort(training group: n=75; internal validation group: n=25) and an external validation cohort(n=10). Pathologists confirmed the status of lymph node. The ResNet101 model was pre-trained on ImageNet and utilized for transfer learning. The ResNet101 was employed to extract deep learning features(DLFs) from BUS and CEUS images. Additionally, the Genetic Programming-based Symbolic Regression(GPSR) algorithm was used to combine the radiomic features(RadFs) and DLFs to generate deep learning radiomic features(DLRFs). Finally, the DLR models were constructed based on eXtreme Gradient Boosting algorithm.

Results: LNM occurred in 48 of 110(43.64%) HCCA patients. 847 RadFs and 4095 DLFs were extracted from the region of interest(ROI) of each tumor. After data cleaning and feature selection, 10 RadFs(BUS:4, CEUS:6) and 27 DLFs(BUS: 5, CEUS: 22) were obtained. After GPSR algorithm, 5 BUS-DLRFs, 10 CEUS-DLRFs, and 15 Combination-DLRFs were obtained and three corresponding DLR models were established, respectively. In the internal/external validation group, the AUC of BUS-DLR/CEUS-DLR/Combination-DLR models were 0.70 vs. 0.77 vs. 0.83(internal validation group) and 0.66 vs. 0.68 vs. 0.72(external validation group).

Conclusion: The DLR models based on DLRFs could better predict preoperative LNM in HCCA, and could further improve the detection rate of LNM to enhance clinical decision-making.

AI in Hepatitis B Screening: A Machine Learning Approach to Demographic Determinants

Minh H. N. Le1,2,3,4, Phat K. Huynh5, Thanh V. Kim6,7, Diem V. B. Dao1, Trang N. D. Pham8, Thuy Nguyen9, Hong K. Tang3, Doan Y. Dao1,4, Nguyen Q. K. Le10

1International Ph.D. Program in Medicine, College of Medicine, Taipei Medical University Taipei Taiwan, 2Research Center for Artificial Intelligence in Medicine, Taipei Medical University Taipei Taiwan, 3ALBioMed Research Group, Taipei Medical University Taipei Taiwan, 4Vietnam Viral Hepatitis Alliance Reston, VA USA, 5Industrial & Management Systems Engineering department, University of South Florida Tampa, FL 33620 USA, 6Center of Excellence for Liver Disease in Viet Nam, Johns Hopkins University School of Medicine Baltimore, MD USA, 7Department of Epidemiology, Pham Ngoc Thach University of Medicine Ho Chi Minh City Viet Nam, 8School of Public health, University of Illinois at Chicago Chicago, IL USA, 9HIV Dynamics and Replication Program, National Cancer Institute, National Institutes of Health Frederick, MD 21702 USA, 10Professional Master Program in Artificial Intelligence in Medicine, College of Medicine, Taipei Medical University Taipei Taiwan

Background: Hepatitis B Virus (HBV) affects nearly 300 million people globally, yet approximately 1/10 of these cases remain underdiagnosed. The primary objective is to assess the efficacy of AI (machine learning) and statistical models, particularly logistic regression for HBV screening using demographic factors.

Methods: Data from a HBV screening seroprevalence survey in Ho Chi Minh City (2019-2020) were analyzed, involving 17600 participants aged 18+ from an estimated 20000 sample using multi-stage cluster sampling. The dataset covered variables like HBsAg, demographics, and KAP questionnaire responses. MATLAB R2023b was used to process the data. SMOTE was used to fix imbalance data. Feature selection included Recursive Feature Elimination (RFE), Tree-Based Feature Importance (TBFI), minimum Redundancy Maximun Relevance (mRMR), and Pearson’s correlation. Key features were interactivally chosen. Classifiers used were Medium Tree (MT), Bilayered Neural Network (BNN), Logistic Regression (LR), Linear SVM, and Fine k-Nearest Neighbors (FKNN). Model performance was assessed via cross-validation, ROC curves, and confusion matrices.

Results: Of the initial 20,000 participants, 14,675 (73.4%) were included in the final analysis. Among them, 1,096 were HbsAg (+), and 6,086 were non-infected (negative for both HBsAg and anti-Hbc), with a median birth year of 52 ± 14. The feature selection by RFE and TBFI identified show best performance, finally seven significant features associated with HBsAg positivity were found. Performance analysis showed Medium Tree = 92.6%, BNN = 92.5%, Linear SVM = 91.7%, LR = 91.7, FKNN = 87.8%.

Conclusion: Machine learning models demonstrate significant potential in screening for HBV infection using demographic data.

Deep Learning Algorithm Applied to Plain CT Images to Identify SMA Abnormalities

Zhongzhi Jia1

1The Affiliated Changzhou Second People’s Hospital of Nanjing Medical University changzhou China

Purpose: To develop a DL model for detecting SMA abnormalities on plain CT and evaluate its performance in comparison with a clinical model and radiologist assessment.

Materials and Methods: A total of 1048 patients comprised the internal (474 with SMA abnormalities, 474 controls) and external testing (50 with SMA abnormalities, 50 controls) cohorts. The internal cohort was divided into the training cohort (n = 776), validation cohort (n = 86), and internal testing cohort (n = 86). A total of 5 You Only Look Once version 8 (YOLOv8)-based DL submodels were developed.

Results: Of the submodels, YOLOv8x had the best performance. The area under the curve (AUC) of the YOLOv8x submodel was higher than that of the clinical model (internal test set: 0.990 vs 0.878, P = .002; external test set: 0.967 vs 0.912, P = .140) and that of all radiologists (P < .001). The YOLOv8x submodel, when compared with radiologist assessment, demonstrated higher sensitivity (internal test set: 100.0% vs 70.7%, P = .002; external test set: 96.0% vs 68.8%, P < .001) and specificity (internal test set: 90.7% vs 66.0%, P = .025; external test set: = 88.0% vs 66.0%, P < .001) and shorter inference time (internal test set: 1.04 min vs 94.80 min, P < .001; external test set: 1.24 min vs 104.80 min, P < .001).

Conclusion: Using plain CT images, YOLOv8x was able to efficiently identify cases of SMA abnormalities. This could potentially shorten the time to diagnosis and thus improve clinical outcomes.
stimulations, including hepatectomy, by conversion of stored retinyl ester into retinoic acid, and thereby associate with liver regeneration. Retinoid x receptor-α (RXRα), one of the retinoid nuclear receptors, forms heterodimer with the other nuclear receptors, and regulates downstream gene expressions. Thus, RXRα functions as a master regulator of retinoid signaling; however, the role of RXRα in liver regeneration remains unclear.

Methods: We used transgenic (TG) mice in which the expression of a dominant-negative form of RXRα is induced by doxycycline administration. Mice lacking the transgene were used as control. First, both TG and the control mice (Male, 10-12 weeks of age) were subjected to 70% partial hepatectomy (PH). Then, the liver/body weight ratio, serum alanine aminotransferase (ALT) levels, and liver histology on days 0, 1, 3, and 7 after PH were compared between the two groups.

Results: The liver/body weight ratios of TG mice at day 3 were significantly lower than that of the control. The infiltration of inflammatory cells and serum ALT levels were comparable between the two groups. The number of Ki67-positive liver cells in TG mice were significantly decreased on day 1, but increased significantly on day 3 compared to that of control.

Conclusions: RXRα plays a role in liver regeneration in mice by regulating the proliferation of liver cells at early time points after PH. Thus, targeting RXRα could be a therapeutic strategy for liver regeneration.

Background: Exosomes (EXOs) were involved in acute lung injury (ALI) in hemorrhage shock. Therefore, this study aimed to investigate the role of EXOs in the activation of hepatic macrophage (Mfs) and ALI in a rat sepsis model.

Methods: In rats undergoing cecal ligation and puncture (CLP), EXOs were isolated by the centrifugal method from blood and administered intravenously to normal rats. Lung tissues and blood samples were harvested. Pathophysiological changes in the lung, the lung wet/dry weight ratio, and the lung microvascular permeability were assessed. Furthermore, plasma inflammatory cytokine levels were measured. In another set of experiments, the production of inflammatory cytokines by isolated hepatic macrophages (Mfs) was assessed in vitro. Moreover, the mechanism of a signaling cascade of activation of Mfs was investigated.

Results: Pulmonary interstitial edema, inflammatory cell infiltration, microhemorrhage, and microthrombosis were observed in lung tissues in normal animals administered with EXOs; however, the extent of these changes was not as severe as in animals undergoing CLP. These pathophysiological changes were blunted by the deletion of hepatic Mfs by clodronate-liposomes in vivo. Inflammatory cytokine production by hepatic Mfs also increased by EXOs and was inhibited in cells cocultured with toll-like receptor (TLR) 4 antibodies in vitro.

Conclusion: In conclusion, EXOs isolated from blood in sepsis are triggering the production of inflammatory cytokines by hepatic Mfs via TLR-4 signaling, and are partly involved in ALI

The effect of portal diversion model in dog for the liver function

Naoki Hashimoto

1Sanda city hospital Sanda city Japan

Portal blood consists of mesenteric and splenic venous blood. In order to determine which one is more important in maintaining liver functions, canine models of a splenocaval shunt (SC shunt) and small bowel autotransplantation (partial mesocaval shunt, MC shunt) which diverts small bowel venous outflow into the systemic circulation and leaves the gastric,duodenal, pancreatic and colonic venous outflow un-disturbed was produced, and metabolic changes of the two models was compared. There was no difference in serum amino acid and ammonia levels in the two models. But amount of hepatic ATP in the MC shunt model is lower compared to the control and the SC shunt model. These data suggest that venous blood supply from the small intestine may be more important in maintaining ATP amount in the liver. Therefore, portal drainage, which reestablishes the physiological route of venous outflow, may be more preferable in small bowel transplantation.

Hyperproliferation in Biliary Cancer and Injury
Upregulated WNT Signaling is Associated with Biliary Proliferation

Mamun Mahtab, Musararat Mahtab, Sheikh Mohammad Fazle Akbar, Tasnim Mahmud, Md. Sunan Bin Islam
1Interventional Hepatology Division, Bangabandhu Sheikh Mujib Medical University Dhaka Bangladesh, 2North South University Dhaka Bangladesh, 3Ehime University Graduate School of Medicine Ehime Japan, 4North South University Dhaka Bangladesh, 5Ibrahim Medical College (BIRDEM) Dhaka Bangladesh

Bangladesh has a rich heritage of traditional medicine with coexistence of Hekimi or Muslim and Ayurveda or Hindu traditional medicines within the political boundary of today’s Bangladesh. However today’s unfortunate reality remains that in Bangladesh, we have not been able to retain our glory. When our neighboring India is doing so good with Ayurveda and even have a separate Ayush Ministry, we are trailing behind in this area despite having such rich heritage. It is now one of our principal research focus to revive our traditional herbal medicine. We have already demonstrated the beneficial effects of Glycyrrhiza Glabra (joshtimodhu) in end stage hepatocellular carcinoma. Recently during the COVID-19 pandemic our study revealed that hospital stay could be shortened with Glycyrrhiza Glabra (joshtimodhu) and Terminalia Arjuna in end stage hepatocellular carcinoma. Currently we are focusing on non-alcoholic fatty liver disease. We are exploring the prospects of Andrographis Paniculata (kalomegh) and Terminalia Arjuna (arjum). We are collaborating with a galaxy of public-private universities in our humble effort to revive our glory. Our initial experience with Kalomegh in fatty liver is encouraging.

Tumor infiltrating immune cells in hepatocellular carcinoma differs according to the viral status

Takashi Kokudo, Masaya Sugiyama, Nobuyuki Takemura, Yuhi Yoshizaki, Fuminori Mihara, Fuyuki Inagaki, Norihiro Kokudo
1National Center for Global Health and Medicine Tokyo Japan

Background: Tumor infiltrating immune cells play an important role in the prognosis of hepatocellular carcinoma (HCC). The HCC development has several aetiologies, which may lead to differences in the types of cells that constitute the tumour tissue. In this study, a comparison of the immune cells constituting the human tumour tissue was performed using single-cell RNA-seq analysis. Specifically, HCV-, HBV- and non-B-non-C (NBNC)-derived HCC were compared.

Methods: A total of 35 HCC patients were enrolled in this study, consisting of 9 HCV, 12 HBV and 14 NBNC-derived HCC. Fresh liver tissue obtained by hepatectomy was used for single cell RNA-seq analysis using a 10x genomics device. After NGS analysis, tumour-infiltrating immune cells were classified based on gene expression patterns.

Results: The tumour-infiltrating immune cells could be divided into 48 clusters based on gene expression patterns. The profile of clusters and cell types was similar between the NBNC and HBV-positive groups, but the HCV-positive group showed distinct profiles. In the HCV-positive group, the proportion of type 3 innate lymphoid cells (ILC3) and CD8-positive NKT cells were increased approximately 5.4-fold and 4.2-fold, respectively, compared to the other group. M2 macrophages were frequently observed in the HBV-positive and NBNC groups at 22.2-fold and 4.7-fold, respectively, compared to the HCV-positive group. Interestingly, a monocytic expressing CD14 positive population was frequently observed in the NBNC group at approximately 3.6-fold compared to the HCV- and HBV-positive groups.

Conclusions: This study has revealed significant differences in the infiltrating immune cells in different aetiologies.

Upregulated WNT Signaling is Associated with Biliary Hyperproliferation in Biliary Cancer and Injury

Nataliya Razumilava, Ashley N. Calder, Junya Shiota, Mirabelle Q. Peter, John W. Tobias, Erik J. Wamsteker, Linda C. Samuelson
1University of Michigan, School of Medicine Ann Arbor United States, 2Nagasaki University Nagasaki City Japan, 3University of Pennsylvania Philadelphia United States

Background: Cholangiocyte hyperproliferation is a hallmark of incurable biliary cancer, cholangiocarcinoma, and cholangiopathies. To develop effective therapies, we need better understanding of the mechanisms regulating aberrant cholangiocyte proliferation. Developmental WNT signaling has been implicated in cell proliferation and stem cell regulation in the liver.

Aim: to uncover the role of WNT signaling in cholangiocyte proliferation in the understudied extrahepatic bile ducts (EHBDs).

Methods: To examine gene expression and localization in human EHBDs, we performed bulk RNA-seq analysis of human biliary organoids, in vitro biliary progenitor cell models, and interrogated cholangiocarcinoma/normal EHBD samples from The Cancer Genome Atlas (TCGA) and our biobank. In mice, we conducted bulk and single-cell RNA-seq analysis of EHBDs at homeostasis and after injury with bile duct ligation (BDL). We used human and mouse biliary organoids and in vivo mouse models to examine WNT effects on cholangiocyte proliferation.

Results: Organoid analysis revealed WNT7B as the predominant ligand in human and mouse cholangiocytes. Human cholangiocarcinoma samples (TCGA) demonstrated increased proliferation (KI67) and WNT7B, Wnt7b and WNT target genes (Birc5, Cd44, Cnd1) were up-regulated in mouse EHBDs post-BDL and localized primarily to cholangiocytes in human and mouse EHBDs. In vitro, cholangiocyte-secreted WNT ligands activated canonical WNT signaling to induce organoid growth. In vivo, inhibition of WNT ligand secretion resulted in decreased biliary proliferation post-BDL.

Conclusions: WNT signaling is upregulated in cholangiocarcinoma and post-EHBD injury. WNT signaling inhibition decreases EHBD cholangiocyte proliferation. Understanding of aberrant WNT-induced biliary proliferation can inform therapeutic strategies for cholangiocarcinoma and cholangiopathies in humans.

Conclusions: This study has revealed significant differences in the infiltrating immune cells in different aetiologies.
non-responders. Here, we used CyTOF analysis on sequential peripheral blood mononuclear cell (PBMC) samples from ICI-treated primary liver cancer (PLC) patients undergoing ICI-based therapy, and established a non-invasive and efficient model to predict clinical response before immunotherapy. This model could enhance clinical care, aiding in PLC patient stratification for ICI-based treatment and fostering new response monitoring strategies.

**HBV virus-host chimera DNA serves as a personalized circulating biomarker for residual tumors of HCC**

Pei-Jer Chen¹, Gar-Yang Chau², Wei-Chen Lee³, Ming-Chih Ho⁴, Teng-Wei Chen⁵, Rey-Heng Hu⁶, Tsung-Han Wu⁷, Hao-Jan Lei⁸, Shu-Cheng Chou⁹, Hisu-Lang Fan¹⁰, Ting-Jung Wu¹¹, Cheng-Maw Ho¹², Hong-Shiue Chou¹³, Sheng-Tai Tzeng¹⁴, Shiou-Hwei Yeh¹⁵

¹National Taiwan University College of Medicine Taipei Taiwan, ²Taipei Veterans General Hospital Department Surgery Taipei Taiwan, ³Linkou Chang Gung Memorial Hospital Taoyuan Taiwan, ⁴National Taiwan University Hospital Taipei Taiwan, ⁵Tri-Service General Hospital Taipei Taiwan, ⁶TCM Biotech International Corp. Taipei Taiwan

**Background:** Timely detection of minimal residual tumor for hepatocellular carcinoma (HCC) is helpful in recurrence monitoring and evaluating treatment strategies. This study examined the feasibility of HBV virus-host chimera DNA (vh-DNA) as a personalized circulating biomarker for residual tumors after surgery.

**Methods:** The tumor-specific vh-DNA integration sites were determined in 148 HBV-related HCC patients by next-generation sequencing. For each individual HCC, vh-DNA was quantified using a customized droplet digital PCR (ddPCR) assay in plasma samples collected within 14 months after surgery, and the results were compared with the clinical outcomes.

**Results:** HBV integrations were identified in 132 out of 148 patients with HBV-related HCC (89.2%). Among the 116 patients who completed the postoperative follow-up, the positive predictive value (PPV) of vh-DNA for tumor recurrence was 68% (17/25), and the negative predictive value (NPV) was 92% (84/91). The mean leading time of vh-DNA detection was 140 days earlier than computed tomography scanning. A total of 78% (18/23) of recurrences originated from the same HCC clones sharing the same vh-DNA, suggesting that most of the early recurrence came from residual tumor cells. Moreover, multivariate cox regression analysis showed that vh-DNA was an independent risk factor for predicting early recurrence. When vh-DNA combined with serum AFP, the sensitivity and specificity of recurrent HCC were 92% and 88%, respectively.

**Conclusion:** This study demonstrates that utilizing vh-DNA to monitor the presence of residual tumors after surgery could be a promising solution for prognosis assessment, recurrence monitoring, and guiding adjuvant therapies in the future.
Chemoprotective mechanisms of skullcapflavone in aflatoxin-induced toxicity in THLE-3 hepatocytes

Glenn Oyong¹, Maria Carmen Tan²

¹Department of Physics, College of Science, De La Salle University 0922 Manila Philippines, ²Department of Chemistry, College of Science, De La Salle University 0922 Manila Philippines

The protective effect of skullcapflavone I (SKI) against aflatoxin B1 (AFB1)-induced cytotoxicity and genotoxicity in THLE-3 cells including possible mechanisms were investigated. SKI previously elucidated and isolated from Andrographis paniculata were tested to be biocompatible with THLE-3. THLE-3 were treated with or without SKI for 24 h before AFB1 exposure. Expressed Akt, Bcl-2, and CYP2E1 transcripts were detected by qRT-PCR. Immunoblotting was performed for translated CYP2E1 including Akt and ERK1/2 phosphorylation. GST activity and AFB1 genotoxic metabolite, aflatoxin B1-8,9 epoxide (AFBO), were quantified. Comet assay was performed to assess DNA damage. AFB1 significantly downregulated the gene and protein expression products of Akt, Bcl-2 while upregulating CYP2E1. Akt phosphorylation was inhibited while increased ERK1/2 activation was observed. High percentages of comet tail length and moment indicated DNA damage. Pre-treatment with SKI afforded cytoprotective effect in THLE-3 viability with half-maximal effective dose of 8.46 μg/mL. SKI pre-treatment reversed AFB1-induced activities through dynamic Akt, Bcl-2 upregulation and CYP2E1 downregulation. Moreover, Akt activation increased while ERK1/2 phosphorylation was inhibited. GST activity significantly increased accompanied by decreased AFBO. Comet tail length and moment were comparable with untreated controls. Remarkably, LYS294002, a specific inhibitor of PI3K, impaired SKI protective effect on THLE-3 suggesting the role of the pathway. This study is the first report describing the protective activities of SKI against AFB1-induced toxicity on human hepatocytes and may help contribute to the development of pharmaceutical leads targeting aflatoxin poisoning and carcinogenicity.

Urine Interleukin-18 (uIL-18) as a Prognostic Marker for Mortality Risk in Liver Cirrhotic

Dwijo A Sindhughosa¹, I K Mariadi¹
¹Division of Gastroenterology-Hepatology, Department of Internal Medicine, Udayana University, Denpasar, Bali, Indonesia

Background: Urine interleukin-18 (uIL-18) has shown to provide prognostic value for several diseases. The release of uIL-18 may reflect the severity of inflammation and the ongoing pathological processes within the liver. Identifying additional biomarkers that can enhance prognostic accuracy in liver cirrhotic patients is essential. This study aimed to evaluate uIL-18 as a prognostic indicator to determine higher mortality risk in liver cirrhotic patients.

Methods: This was an analytic cross-sectional study to determine the risk of high uIL-18 for higher risk of mortality according to MELD score. Subjects with MELD score ≥20 were considered had higher risk for mortality. The level of uIL-18 measured with ELISA method. Cut-off of high uIL-18 was determined with Youden Index.

Results: A total of 75 subjects involved in this study with mean age of 54.71 ± 11.06 years. Majority of the subjects were male (78.7%). A total of 33 subjects (44%) had higher risk of mortality. The median of uIL-18 was 79.49 (386.63) ng/mL. The cutoff for uIL-18 was 36.87 ng/mL to provide the best value (youden index = 0.29). By using the optimal cutoff, the sensitivity was 78.8%, specificity 50%, positive predictive value 55.3%, negative predictive value 75%, accuracy 62.6%. High uIL-18 associated with higher risk for mortality by 6.55 times (p = 0.011).

Conclusion: uIL-18 provides good specificity and validity to determine higher risk for mortality in liver cirrhotic. uIL-18 could be used as a complementary prognostic indicator, facilitating more precise risk stratification and guiding therapeutic decisions for high-risk liver cirrhosis population.

Evaluation of Tumor Microenvironment in HCC by TCRA Gene and Transcriptome Deconvolution Analysis

Hitoshi Mochizuki¹,², Yosuke Hirotsu¹, Yuji Iimuro³, Masao Omata²,⁴
¹Yamanashi Central Hospital , Genome Analysis Center Yamanashi Japan, ²Yamanashi Central Hospital, Department of Gastroenterology Yamanashi Japan, ³Yamanashi Central Hospital, Department of Hepatobiliary and Pancreatic Surgery Yamanashi Japan, ⁴The University of Tokyo Tokyo Japan

Introduction: The indications for immune checkpoint inhibitors (ICIs) are expanding and their efficacy is recognized, but the predictors of efficacy are not as simple as previously thought. Tumors have limitations in conventional approaches because they require consideration of not only the malignancy and tumor-infiltrating lymphocytes (TILs), but also the tumor microenvironment (TME), which consists of many stromal cells and their activation states. We analyzed the TCRA (T cell receptor omega) gene and transcriptope to determine the probability of the presence of various immunocompetent cells and stromal cells in relation to ICI treatment efficacy.

Methods: DNA was extracted from tumor tissue FFPE operated on at our hospital, and the probability of cell presence was calculated by machine learning using a generalized additive model (Cell Exome TREC Tool. Nature 2021) using the process of elimination of delta strand from TCRA (n=522). Transcriptome analysis was performed from mRNA and cell composition was calculated using deconvolution method (n=251). 22 immune system cell types were identified in Cibersort (Nat Methods 2015) and 64 cell types (immune system cells, epithelial cells, stromal cells) were identified in xCell (Genome Biology 2017). cells, and stromal cells) were annotated to evaluate the efficacy of ICI treatment and irAE.

Results: Compared to other cancer types, hepatocellular carcinoma has a low ratio of immunocompetent cells. It is necessary to take into account the intra-tumor heterogeneity and differences in the algorithms used to evaluate the immune environment, and further analysis using an integrated machine learning framework will be required in the future.

Serum anti-PD-1 autoantibody predicts survival of HCC receiving atezolizumab/bevacizumab

Akinobu Takaki¹, Yuki Sasaki¹, Masahiko Sue¹, Nozomi Miyake¹, Takuya Adachi¹, Nozomu Wada¹, Yasuto Takeuchi¹, Hideki Onishi¹, Hidenori Shiraha¹, Motoyuki Otsuka¹
¹Department of Gastroenterology and Hepatology, Okayama University Okayama Japan
Abstract

Background & Aims: In patients with advanced hepatocellular carcinoma (HCC), atezolizumab (anti-programmed cell death-ligand 1 [PD-L1]) and bevacizumab (anti-vascular endothelial growth factor) combination therapy (Atezo/Bev therapy) is a first-line treatment. However, no reliable biomarkers are currently available to predict its efficacy. Here, we examined serum anti-programmed cell death-1 (PD-1) autoantibody levels as candidate biomarkers.

Methods: Patients with advanced HCC from four institutions participating in the Okayama Liver Cancer Group were prospectively registered and underwent Atezo/Bev therapy. A total of 63 patients were enrolled between November 2020 to October 2022. Serum anti-PD-1 autoantibody levels were measured before treatment using an indirect enzyme-linked immunosorbent assay (ELISA). The correlation between the titers and response to therapy was statistically examined.

Results: Serum anti-PD-1 autoantibody levels were not significantly associated with the treatment response in any patient. However, when examining only patients who received the Atezo/Bev as their first-line therapy, higher anti-PD-1 autoantibody levels were significantly associated with worse overall survival (OS) rates. The titer was an independent risk factor for poor prognosis (odds ratio [OR], 7.8; 95% confidence interval [CI], 1.5-39; p = 0.013), in addition to a higher neutrophil-to-lymphocyte ratio (OR, 7.1; 95% CI, 1.6-31; p = 0.009) and lower albumin levels (OR, 14.2; 95% CI, 2.38-84.9; p = 0.003).

Conclusion: Serum anti-PD-1 autoantibody levels correlated with the OS rate in patients who received Atezo/Bev as first-line therapy. Serum anti-PD-1 autoantibody levels may serve as new biomarkers for predicting the efficacy of immune checkpoint inhibitors in patients with HCC.

Background: Xanthine oxidoreductase (XOR) is highly expressed in the liver, but the number of the study regarding XOR activities in patients with hepatic diseases was few, and the several etiologies were analyzed combinatorially. Recently, high-sensitive and accurate assay for the measurement of XOR activity has been developed.

Methods: We performed a prospective multi-institutional cross-sectional study in which the enrolled numbers of patients and controls were 329 and 32, respectively. We measured plasma XOR activities and purine metabolism-associated markers in etiology-based comprehensive liver diseases by using the novel method. We also analyzed the relationship between the plasma XOR activities and parameters of liver tests, purine metabolism-associated markers, oxidative stress markers, and an inflammation marker.

Results: Plasma XOR activities were generally increased in various liver diseases compared with those in control subjects. The highest activities were observed in a patient with acute hepatitis B. The XOR activities were likely to be high in the active phase. For example, the XOR activities in chronic hepatitis C were significantly higher in patients with active infection than past infection and in those with un- cured hepatocellular carcinoma patients than cured ones. Most importantly, the XOR activities were significantly associated with parameters of liver tests, especially serum ALT levels, regardless of etiology and plasma xanthine levels.

Conclusions: The plasma XOR activities might reflect the active phase in various liver diseases. The longitudinal studies such as the comparison of plasma XOR activities between acute phase and recovery phase in various liver disease are needed to verify our results.

Autophagy-Related Genes Promote Development of Pediatric Metabolic-associated Fatty Liver Disease
Baiyi Liu1, Xiaoxiao Wang1, Rui Jin1, Zilong Wang1, Yuyun Song1, Xiaole Li1, Feng Liu1, Huiying Rao1
1Peking University People's Hospital Beijing China

Background: Metabolic-associated fatty liver disease (MAFLD) is the most common cause of chronic liver disease worldwide. With an increasing number of overweight or obese children, MAFLD has emerged as one of the most common comorbidities in the pediatric obese population. Currently, the precise pathophysiology of pediatric MAFLD is still not completely understood.

Methods: Pediatric MAFLD dataset and autophagy-related genes (ATGs) were selected for identifying differentially expressed genes (DEGs). Then, protein-protein interaction (PPI) network were integrated to identify the hub genes as gene signature. Next, receiver operating characteristic (ROC) curves were used to evaluate the performance of gene signature. Last, we analysed the the hub genes for expression levels and correlation with immune cells.

Result: We identified six autophagy-related genes (KDR, MYC, VEGFA, CXCR4, IFNG and CCL2) as hub genes, that may be closely related to the development of pediatric MAFLD. Furthermore, we constructed prognosis gene markers based on the hub genes. This gene signature has shown good diagnostic accuracy in both obese and MAFLD pediatric population (AUC > 0.6). Compared with mild liver fibrosis, expression level of MYC, CXCR2 and CCL2 significantly increased in advanced liver fibrosis in pediatric MAFLD. In addition, according to the immune cells composition, macrophage M2 significantly increased in pediatric MAFLD which was the opposite of adult MAFLD.

Conclusion: The six hub genes may predict the risk of MAFLD development in pediatric population by mediating autophagy-related mechanism, which is hopeful to be biomarkers for predicting occurrence, diagnosis and treatment of MAFLD.

Exploration of the potential biomarker between COVID-19 and liver cirrhosis-hepatocellular carcinoma
Ning Wang1
1Tianjin Third Central Hospital Tianjin China

Background: Coronavirus disease 2019 (COVID-19) pandemic is attributed to the severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) infection, which has widespread impacts on the patients with underlying disease. It is well known that liver cirrhosis (LC) has been coined as a very strong risk factor for the development of hepatocellular carcinoma (HCC). This study aimed to explore the potential gene signature and regulatory network between COVID-19 and LC-HCC.

Methods: The candidate gene signatures were identified by the common differentially expressed genes (DEGs) based on COVID-19 and LC-HCC utilizing the bioinformatics analysis. Subsequently, the gene functional enrichment analysis (KEGG and GO) and protein-protein interaction (PPI) network were performed, exploring the hub gene as the key biomarker. Finally, receiver operating characteristic (ROC), biological function and gene expression network analyses were systematically conducted.

Results: The common 78 candidate gene signatures were successfully screened out between COVID-19 and LC-HCC. Then, KEGG and GO enrichment analyses discovered that these candidate genes were mainly involved in the cell cycle. Based on the construction of PPI network, the hub gene CDK1 was successfully identified by means of ten scoring methods. ROC analysis confirmed that CDK1 exhibited a high predictive efficacy in COVID-19 (AUC = 0.955) and LC-HCC (AUC = 0.946) cohorts. Additionally, HCC patients with high CDK1 expression had poor clinical prognosis.

Finally, the comprehensive gene regulatory networks were established.

Conclusions: This study successfully determined the key biomarker and gene regulatory network between COVID-19 and LC-HCC, contributing to predicting patients’ prognosis and therapeutic targets.

Diagnosis of HBV-associated liver cirrhosis and HCC based on Lipid and peptide fingerprints
Liye Tao1, Zefeng Shen1, Xuetong Qu2, Xinrong Jiang2, Yingyue Liu2, Junhao Zheng1, Chao Song1, Yang Liu3, YangYang Xie3, Haoyu Pan2, Shihao Li3, Yali Wang2, Junjie Xu2, Jianmin Wu3, Xiao Liang2
1Sir Run Run Shaw Hospital, Zhejiang University School of medicine Hangzhou China, 2Zhejiang university Hangzhou China

Background: In this study, biological changes will be explored during the development of HBV-related HCC based on serum lipids and peptides and a classifier will be constructed to identify patients at different stages in the HBV-infected population.

Methods: A total of 846 serum samples were collected from 219 healthy volunteers, 206 patients with chronic hepatitis B (CHB), 160 patients with HBV-related LC and 261 patients with HBV-related HCC, and the lipid and peptide fingerprints were acquired based on Nano-assisted laser desorption ionization time of flight mass spectrometry. Then molecular landscape was analyzed and the stepwise prediction model was conducted.

Results: We found that serum lipid and peptide fingerprints were altered during the evolution from CHB to HCC. The stepwise prediction model was built, which could identify 80.0% HC, 80.9% CHB, 55.6% LC and 90.0% HCC in the external test set. And 95.5%-98.6% of AFP negative HCC patients could be identified by the multi-omics model. When combined with AFP, the sensitivity for identifying HCC patients could reach 97.9%-98.3%.

Conclusions: Platform of acquiring lipid fingerprints and peptide profiling based on NALDI-TOF-MS had clinical application potential in identifying different stages during the evolution of CHB to HCC, which may be a supplementary method of AFP for screening and diagnosis of HBV-related HCC. Chictr.org.cn number, ChCTR2000073462.

Identification of Alcoholic Hepatitis-related genes and Mesenchymal Stem Cell treatment Target Genes
SEUL KI HAN1,2, Taesic Lee3,4, Jisun Lim1, Hyunsoo Kim1, Young Uh5, Moon Young Kim1,2,3
1Department of Internal Medicine, Division of Gastroenterology and Hepatology, Wonju Severance Christian Hospital, Yonsei University Wonju College of Medicine W, 2Department of Gastroenterology and Hepatology, Wonju Severance Christian Hospital, Yonsei University Wonju College of Medicine W, 3Division of Gastroenterology and Hepatology, Yonsei University Wonju College of Medicine W, 4Division of Metabolism and Molecular Biology, Yonsei University Wonju College of Medicine W, 5Division of Metabolism and Molecular Biology, Yonsei University Wonju College of Medicine W

Background: Alcoholic Hepatitis (AH) is a severe liver disease caused by chronic alcohol consumption, characterized by severe inflammation, necrosis, and fibrosis. Mesenchymal Stem Cell (MSC) therapy has been shown to be effective in treating AH.

Methods: Blood samples were collected from patients with AH and healthy controls. Gene expression analysis was performed using microarrays and qPCR. The treatment response was evaluated using the taqman gene expression analysis platform.

Results: A total of 500 genes were identified as differentially expressed between AH and controls. The top ten genes were identified using the R programming language. The treatment response was evaluated using the taqman gene expression analysis platform.

Conclusions: Identification of AH-related genes and MSC treatment target genes was successful. The results provide a potential therapeutic target for AH treatment using MSC therapy.
Alcoholic hepatitis (AH) is a life-threatening condition and widespread chronic liver condition that places patients at risk of short-term mortality if it is not properly managed. This study aimed to identify transcriptomic biomarkers and cell therapy targets for AH.

We conduct a systematic meta-analysis of published human gene expression studies on liver biopsies and blood derived gene data. First, three liver AH transcriptome datasets and a blood AH dataset were combined to discover a common phenotype. Second, two AH prognosis datasets were compiled, which are including gene phenotype reflecting prognosis. Using inverse weighted variance-based method mounted in METAL software, the candidate genes related to AH in liver and blood tissues and annotated them as the liver-blood AH meta genes. Third, three MSC datasets were curated for gene identification in stem cell response. Meta-analysis was implemented on the individual cohort-specific summary statistics obtained from differential expression methods to identify the AH-related biomarkers. To narrow down the candidate hub genes among stem cell treated data, TF database, protein-protein interaction network, disease-gene association database, and disease- and expression-related SNP database were used to analysis.

With previously identified alcoholic gene-related databases, external verification was performed and finally 47 upstream AH-related genes were presented.

We present key genes involved in the progression of AH and provide a meta-analysis of results in a objective, statistically-based format. And at the same time, we suggest this biomarkers that can predict the prognosis of AH and treatment response.

Conclusion: It is important to design comprehensive hepatitis education initiatives to address patient knowledge gaps since there are misconceptions surrounding HBV and HCV.

Abstract Submission No. 100992

A community-centered surveillance program for disease severity map in an under-resourced region

Jee-Fu Huang1, 2, 3, Pei-Chien Tsai1, Ming-Lung Yu1, 4, Chia-Yeen Dail1, 2, Wan-Long Chuang5

1Kaohsiung Medical University Hospital Kaohsiung Taiwan, 2Center of Excellence for Metabolic Associated Fatty Liver Disease, National Sun Yat-sen University Kaohsiung Taiwan, 3Hepatitis Center, Kaohsiung Medical University Kaohsiung Taiwan

Background/Aim: Taitung, located in eastern Taiwan, has the lowest population density, the lowest life expectancy, and the lowest medical personnel compared with other prefectures in Taiwan. Liver-related mortality remains one of the major causes of death in Taiwan. The study aimed to elucidate the epidemiological characteristics and the disease severity of liver diseases in Taitung.

Methods: We conducted a mass screening program for those who carried a high-risk for advanced liver disease and did not receive regular liver disease surveillance. The eligible participants were selected from the healthcare database and were invited by email or phone calls via township-based primary care centers. They received FibroScan as the initial surveillance, followed by liver disease tests.

Results: A total of 4,531 residents (1,859 males; mean age= 54.2 ± 14.0 years) participated the program. The prevalence of diabetes, hypertension, and hyperlipidemia were 12.8%, 28.9%, and 12.1%, respectively. There were 302 (6.7%) residents with HBV infection, whereas 49 (1.1%) residents had anti-HCV+. There were 2,044 (45.1%) participants of indigenous background. The prevalence of advanced fibrosis, defined as FibroScan> 9.5 kPa, was 7.0% (316/4,531), ranging from 3.7% to 10.2%. There were 2,874 (63.4%) participants with steatotic liver disease (SLD), defined as Controlled Attenuation Parameter (CAP) value> 238 dB/m. Excessive alcohol use (23.1% vs 6.9%, P= 0.001) and SLD (11.6% vs 4.8%, P< 0.001) were the major factors contributing to advanced fibrosis.

Conclusion: The community-centered surveillance program provided information for disease severity mapping in the under-resourced prefecture.

The Prevalence of Hepatitis B and Hepatitis C Among Police Officers of Rawalpindi, Pakistan

Reham Baig1, Nida Ali2, Qaiser Hussain3, Ehsan Ghani4

1World Health Organization Islamabad Pakistan, 2Coalition for Global Hepatitis Elimination, TFGH Rawalpindi Pakistan, 3Local Hepatitis Elimination and Prevention, District Health Authority Rawalpindi Pakistan, 4District Health Authority Rawalpindi Pakistan

Background: Police officers play a vital role in law-and-order management and during their frontline duty, they often ignore their health. This article explores the prevalence of these infections among police officers and the importance of addressing this issue.

Aims: Assesses the prevalence and risks leading to infection of hepatitis B and C.
Methods: An integrated screening camp was arranged to screen the Rawalpindi police force against communicable diseases. 15705 officers were tested in a month for Hepatitis B and C with rapid testing kits. 98 positive for HCV, 5 with HBV and 4 with coinfection were interviewed to explore various risk factors that lead to the infection.

Results: 0.24%(37/15705) participants were found reactive for HBsAg antigen, 1.85%(209/15705) were reactive for Anti-HCV. Out of 327 positive officers, 108 were interviewed for potential risk factors for acquiring the infection. 33.3%(36) had family member with Hepatitis, 32.4%(35) had dental treatment, 27.7%(30) got IV medications, 25%(27) availed roadside barber services, 13.8%(15) had blood transfusion, 8.3%(9) had multiple sex partners, 2.7%(3) had piercings, 1.8%(2) were trans-genders, 1.8%(2) had IV drugs, 0.9%(1) were men having sex with men and 0.9%(1) got tattoo.

Conclusion: These frontline officers face many challenges in the line of duty, communicable diseases are not to be neglected as 0.24%(37/15705) and 1.85%(209/15705) of officers tested positive for Hepatitis B and C respectively. Major risk factors were positive family members, dental treatments and frequent IV medications. A follow-up viral load testing was done, and those positive were linked to care.

Earlier liver cirrhosis onset in intrafamilial hepatitis Delta Virus transmission in Moldova

Adela TURCANU1,2, Ecaterina Cebanu1, Veronica Cumpata2, Pascal Pineau3

1The State University of Medicine and Pharmacy N.Testemitanu Chişinău, Moldova, 2The Clinic of Gastroenterology and Hepatology Chisinau Moldova, 3Unité « Organisation nucléaire et Oncogénèse », INSERM U993, Institute Pasteur Paris France

Background: Hepatitis delta, sometimes considered as a vanishing disease in Western Europe, is still widespread in the Republic of Moldova.

Methods: In this comparative cross-sectional study, we described demographic features of 224 HDV-infected patients either affected from chronic hepatitis or liver cirrhosis attending care in three Moldovan centers that we compared with 100 hepatitis B virus mono-infected subjects.

Results: All delta-infected patients were anti-HBe and HBV DNA was detectable much less frequently (28%) than in mono-infected ones (76-92%, P<1.0E-09). Familial transmission of the virus was much more prevalent in HDV infection than in HBV infection (39% vs 23%, P=0.0036). Amongst patients with hepatitis delta, those with familial contamination developed liver cirrhosis much earlier than others (40.5±3.9 years vs 46.9±8.7 years, P=0.053) and presented more frequently detectable HDV RNA in their plasma (98.7% vs 89.2%, P=0.0094).

Conclusion: Hepatitis delta is a significant health problem in Moldova. Familial transmission of hepatitis delta, especially prevalent South of the country, is responsible of anticipation of the complications.

Modelling the impact of vaccination on HBV transmission and progress to elimination in Punjab, India

Jack Stone1, Anna McNaughton1, Hannah Fraser1, Dimitris Kalogiros1, Aaron G Lim1, Gagandeep S Grover2, Parag Govil3, Arun Sond3, Yuhui Chan3, Oriel Fernandes1, Peter Vickerman1

1University of Bristol Bristol United Kingdom, 2State Viral Hepatitis Management Unit, Department of Health and Family Welfare, Government of Punjab, Chandigarh Punjab India, 3Clinton Health Access Initiative (CHAI) Punjab India

Background: India was estimated to have 32.7 million persons living with Hepatitis B virus (PLHBV) in 2016. The prevalence of chronic HBV infection (HBsAg-positive) in Punjab, India, was 1.4% in 2014 (~400,000 PLHBV). India has scaled up infant HBV vaccination to 91% coverage and timely birth dose vaccination to 56% coverage, but few receive HBV treatment. The World Health Organization (WHO) HBV elimination targets include decreasing new HBV infections by 95% over 2015-2030 and decreasing HBsAg prevalence among children under five to <0.1% by 2030. We used modelling to evaluate progress towards these targets in Punjab.

Methods: A dynamic HBV transmission model was developed, including disease progression, vertical and horizontal transmission, population growth and vaccination. The model was parameterised and calibrated in a Bayesian framework using regional estimates of chronic (HBsAg-positive) and past infection (HBeAb-positive) prevalence. Indian data on HBeAg-prevalence, demographic data, and yearly data on infant and birth dose vaccination coverage. The model was used to simulate trends in HBV transmission and evaluate the impact of ongoing vaccination.

Results: Projections suggest HBV incidence has decreased by 39.9% (95% credibility interval: 30.5-45.6) over 2015-2022, while HBV-related deaths have remained stable. In 2022, 4.5% (2.2-23.6) of new infections and 19.0% (10.8-54.0) of new chronic HBV infections (CHB) were acquired vertically, with 0.11% (0.07-0.19) of new-borns acquiring HBV infection. Model projections estimate that the annual number of new CHB infections have decreased by 31.8% (19.3-38.7) over 2015-2022 and will decrease by 50.0% (36.3-56.5) by 2030. For under-fives, we project that the HBsAg-prevalence will be 0.08% (0.05-0.15) by 2030; below WHO’s target. Existing vaccinations have averted 16,200 (6,800-34,500) CHB infections over 2007-2022, resulting in 39.6% (31.6-46.3) fewer infections in 2022.

Conclusion: HBV vaccination scale-up in Punjab has had substantial impact but further strategies are needed to reach the WHO HBV elimination targets.

A 10-year assessment of a population-based prospective liver cancer screening project in Zhongshan

Mingfang Ji1, Xia Yu1, Yun Du1, Shifeng Lian2, Biaohua Wu1, Fugui Li1

1Cancer Research Institute of Zhongshan City, Zhongshan City People’s Hospital, 2 Sunwen East Rd., Zhongshan 528403, China. Zhongshan China, 2Unit of Integrative Epidemiology, Institute of Environmental Medicine, Karolinska Institute Stockholm Sweden

Background: A comprehensive, long-term assessment of liver cancer screening programs, comparing populations participating in screening with those not participating, is notably lacking in the global research landscape.

Method: We conducted a community-based screening trial in Xiaolan town, Zhongshan City, Guangdong, China, recruiting residents aged 35-64 years in 2012. In total, 18,185 eligible residents were enrolled in the screening group, while 50,073 residents were included in the non-screening group. Participants in the screening group underwent
testing for hepatitis B virus surface antigen (HBsAg) in serum. Those who tested positive for HBsAg were subsequently invited for alpha-fetoprotein (AFP) testing, liver ultrasonography, and/or computerized tomography twice per year. Liver cancer occurrence, vital survival status, and causes of death were monitored until December 31, 2021, using medical records from hospitals, as well as data from the Zhongshan Cancer Registry, Population Registry, and Cause of Death Registry. We calculated the early detection rate and cumulative incidence of liver cancer among residents in both the screening (HBsAg positive (+) or negative (-)) and non-screening groups. Additionally, we assessed the disparities in overall and liver-cancer-specific survival probabilities between individuals in these groups.

**Results:** With a median follow-up period of 10 years, 432 liver cancer cases occurred. Within the study cohort, comprising 50,073 non-screening residents, 15,295 screening residents with HBsAg (-), and 2,893 screening residents with HBsAg (+), the proportion of liver cancer was 0.6%, 0.2%, and 3.7%, respectively (p<0.01). The early detection rates for these groups were 13.9%, 31.6%, and 29.9%, respectively (p<0.001). The cumulative incidence of liver cancer was highest among screening residents with HBsAg (+) (p<0.001). Furthermore, the cumulative overall survival (p=0.002) and liver-cancer-specific survival (p=0.028) probabilities among liver cancer cases from screening residents with HBsAg (+) were superior to those among cases from screening residents with HBsAg (-) and non-screening residents. Their 1-year overall survival probabilities since diagnosis among screening group versus non-screening group were 53.8% and 34.5%; 3-year overall survival probabilities were 29.4% and 11.3%; and 5-year overall survival probabilities were 27.7% and 6.9%, respectively (all p<0.05). These survival advantages were more pronounced five years after enrollment (Adjusted hazards ratio (aHR): 0.55, 95% confidence interval (CI): 0.41,0.75) than that within five years since enrollment (aHR: 0.99, 95% CI: 0.71, 1.39).

**Conclusion:** This study underscores the importance of proactive liver cancer screening strategies in the early detection of liver cancer. Notably, it highlights the potential to extend the survival probabilities for liver cancer individuals, especially in the long-term perspective.

**Epidemiology of HCC in patients with viral Hepatitis**

Saltanat Maharramzade1, Gulnara Aghayeva2, Elhan Aliyev2

1) Baku Health Centre Baku Azerbaijan, 2) Baku branch of Sechenov Medical University Baku Azerbaijan

**Background:** Hepatocellular carcinoma is the most common cancer in the worldwide, representing more than 5% of all cancers. Liver cirrhosis, age, smoking and drinking, and metabolic risk factors will increase the risk of cancer in HBV/HCV/HDV patients. Viral load, FIB-4, and stiffness of the liver can predict the risk of HCC in patients with viral infection. Moreover, effective prevention strategies are needed to reduce the risk of HCC. Secondary prevention includes effective antiviral treatment for HBV / HCV / HDV to prevent disease progression to HCC.

**Methods:** During period since January 2019 to October 2023, 6240 patients (57% males, 43% females, mean age 34 years±6.5) were included to our study, while 1996 (32%) with Hepatitis B, 4224 (67%) Hepatitis C and 249 (4%) with Viral Hepatitis B and D.

**Results**

Totally HCC was diagnosed in 199 patients (3,2%) , with Hepatitis C 97 (2,3%) , with Hepatitis B 55 (2,8%) and also with Hepatitis B+D - 9 (3,8%) patients.

**Conclusion:** Chronic Viral Hepatitis are most important causes of HCC. Among viral hepatitis HCC often determined in B+D viral hepatitis group. Eliminating the route of transmission and vaccination against Hepatitis B will lead to a decrease in the incidence of HCC.
mild or moderate (97.8%). Vaccination is not a protective factor against the Omicron infection. Meanwhile, six patients with worsening DM symptoms were observed after infection, mainly respiratory and skin symptoms, and four of them were judged as related to COVID-19 infection. The other clinical laboratory indexes were relatively stable in patients after infection. Both wild-type (WT) NAb s titer and BA.5-specific IgG titer were significantly enhanced after infection (p<0.01), which was as high as healthy controls (HC). The memory B cell responses were similar between patients and HC group. But both the WT-specific CD8+ T cell and CD4+ T cell were reduced in anti-MDA5 DM patients. In conclusion, patients with anti-MDA5 DM will not deteriorate the COVID-19, in turn, COVID-19 infection will not increase the risk of anti-MDA5 DM exacerbation. The humor al responses were robust but the cellular responses were weakened in anti-MDA5 DM patients after COVID-19 infection.

Trends of the mortality of cirrhosis in China: an analysis of the China Death Surveillance Database

Xiaoxiao Wang1, Huixin Liu2, Jinlei Qi3, Lijun Wang3, Peng Yin4, Feng Liu5, Lai Wei6, Yu Wang7, Maigeng Zhou1, Huiying Rao1  
1Peking University People's Hospital, Peking University Hepatology Institute, Beijing Key Laboratory of Hepatitis C and Immunotherapy for Liver Diseases, Beijing International Cooperation Base for Science and Technology on NAFLD Diagnosis Beijing China, 2Peking University People's Hospital, Department of Clinical Epidemiology and Biostatistics Beijing China, 3National Center for Chronic Non-communicable Disease Control and Prevention, Chinese Center for Disease Control and Prevention Beijing China, 4Beijing Tsinghua Changgung Hospital, Tsinghua University Beijing China, 5Chinese Foundation for Hepatitis Prevention and Control Beijing China  

Background: China accounted for 14.9% of the total cirrhosis deaths in the world, a detailed and comprehensive understanding of contemporary status of cirrhosis mortality in China will be crucial to establish strategies for intervention and decrease the disease burden of cirrhosis in the world.

Methods: Mortality data from 2008 to 2020 were retrieved from the Disease Surveillance Point system of Chinese Center for Disease Control and Prevention. Crude mortality rate and age-standardized mortality of cirrhosis were exhibited by sexes, residential locations, and regions, respectively. The average annual percentage change (AAPC) of cirrhosis mortality rates from 2008 to 2020 was also calculated.

Results: The crude mortality rate of cirrhosis was 4.57 per 100,000 people in 2020. Compared with females and individuals living in urban areas, females and people living in rural areas had higher age-standardized mortality. The crude mortality rate and age-standardized mortality rate in provinces from southwest China (Guangxi, Yunnan, Guizhou, Qinghai) was higher than that in other provinces. Meanwhile, with the increase of ages, the age-specific mortality rate increased significantly. From 2008 to 2020, the mortality rates of cirrhosis showed a downward trend in China except for males aged 50-59 years, females aged 45-49 years and 80-84 years.

Conclusions: From 2008 to 2020, the mortality rate of cirrhosis showed a decreasing trend in China. In the future, interventions for cirrhosis mortality control need to pay more attention to all males and females aged 45-49 and 80-84 years, people living in rural areas and provinces in southwest China.

Changes in the prevalence of hepatitis B and C viral infections in Sindh province, Pakistan:

Tesfa S Alamneh1,2, Josephine Walker1, Aaron G Lim1, Ejaz Alam1, Saeed Hamid3, Graham R Foster4, Naheed Choudhry5, M.Azim Ansari6, Huma Qureshi7, Peter Vickerman1  
1Population Health Sciences, Bristol Medical School, University of Bristol, Bristol, UK. Bristol United Kingdom, 2Institute of Public Health, College of Medicine and Health Sciences, University of Gondar, Gondar Ethiopia Gondar Ethiopia, 3Pakistan Health Research Council Research Centre, Karachi, Pakistan Karachi Pakistan, 4Aga Khan University, Karachi, Pakistan Karachi Pakistan, 5Queen Mary University of London, London, UK London UK, 6Nuffield Department of Medicine, University of Oxford, Oxford, UK Oxford UK, 7Consultant Gastroenterologist, Doctor Plaza, Clifton Karachi Clifton Karachi Pakistan

Background/Aims: Pakistan harbours a large burden of hepatitis B virus (HBV) and hepatitis C virus (HCV) infection. We utilised repeat sero-surveys to assess progress achieved towards hepatitis elimination in Pakistan.

Methods: Multilevel logistic regression evaluated the change in HBV infection (HBV surface antigen (HBsAg)-positive) prevalence and...
HCV exposure (HCV antibody (HCV-Ab)-positive) prevalence between two sero-surveys from 2007 and 2019 for Sindh province, and associated risk factors. Adjusted Odds Ratios (aOR) were estimated, and population-attributable fractions (PAF) for modifiable risk factors for HCV exposure.

**Results:** The 2007 and 2019 surveys included 8855 and 6672 individuals. HBsAg prevalence decreased from 2.6% (95% confidence intervals (95%CI):2.2-2.9%) in 2007 to 1.1% (95%CI:0.8-1.3%) in 2019, while HCV-Ab prevalence increased from 5.1% (95%CI:4.6-5.5%) to 6.2% (95%CI:5.6-6.8%). The age and gender-adjusted HBsAg prevalence decreased by 80% (aOR=0.2, 95%CI:0.1-0.4) among children and 60% (aOR=0.4, 95%CI:0.3-0.6) among adults over 2007-2019, while HCV-Ab prevalence decreased by 60% (aOR=0.4, 95%CI:0.2-0.7) in children and increased by 40% (aOR=1.4, 95%CI:1.2-1.7) in adults. HCV-Ab prevalence was lower in adults with secondary (aOR=0.6, 95%CI:0.5-0.8) and higher (aOR=0.5, 95%CI:0.3-0.8) education compared to illiterates, and higher among adults reporting blood transfusion (aOR=1.7, 95%CI:1.2-2.4), family history of hepatitis (aOR=2.5, 95%CI:1.9-3.3), past year medical injection (aOR=2.1, 95%CI:1.6-2.7), being tattooed (aOR=1.4, 95%CI:1.0-1.9) and shaved by traditional barber (aOR=1.2, 95%CI:1.0-1.5). Modifiable risk factors accounted for 45% of HCV exposure, with medical injection(s) accounting for 38% (95%CI:25.7-48.4%).

**Conclusions:** Overall HCV has increased over 2007-2019 in Sindh province, while HBV prevalence has decreased. Medical injections should be an important focus of prevention activities.

**Hepatitis A Among Adult Patients Presenting With Acute Hepatitis: A Changing Epidemiological Trend**

Yumna Shahid1, Amna Subhan1, Faisal Wasim1

1Aga Khan University Hospital Karachi Karachi Pakistan

**Background:** For decades, Hepatitis A virus (HAV) had been a leading cause of acute hepatitis among children and was less prevalent among adults. However, recently a paradigm shift has been observed in the epidemiology of HAV evident by cases of acute hepatitis due to HAV among adults. Very limited data is available from Pakistan about the burden of hepatitis A among adults. The study is designed to estimate the frequency of HAV among adult patients with acute viral hepatitis at a tertiary care hospital in Karachi, Pakistan.

**Methods:** This is an ongoing prospective, cross-sectional study, being conducted at Gastroenterology Department Aga Khan University Hospital from January 2022 to November 2023. Patients aged ≥ 18 years who presented with acute hepatitis to emergency or outpatient department were reviewed. Demographic data, clinical and laboratory parameters were recorded and analyzed.

**Results:** A total of 117 patients were found to have acute hepatitis caused by hepatotropic viruses. Most common age group is 18-30. Approximately 64% of cases of acute hepatitis were attributed to HAV followed by 35% of the cases due to HEV, 1% by HBV. Higher levels of ALT and AST were observed among adults with HAV than HEV. Higher proportion of HEV was recorded among pregnant patients. Higher proportion of Acute hepatitis with coagulopathy and ALF were observed among HEV cases than HAV.

**Conclusions:** HAV seems to be the rising cause of acute hepatitis among adults. This signifies the need of improved sanitation, hygiene and a robust vaccination programme against Hepatitis A among adult population.

**Genetic variation in SLC39A8 and risk of hepatocellular carcinoma in the Danish general population**

Anne-Sofie Seidelin1,2, Borge Gronne Nordestgaard3,4, Anne Tybjerg-Hansen1,2, Stefan Stender1,3

1Department of Clinical Biochemistry, Rigshospitalet, Copenhagen University Hospital Copenhagen Danmark, 2Department of Clinical Biochemistry, Herlev and Gentofte Hospital, Copenhagen University Hospital Copenhagen Denmark, 3Department of Clinical Medicine, Faculty of Health and Medical Sciences, University of Copenhagen Copenhagen Denmark

**Background:** Manganese is an important co-factor for numerous biological processes. Multiple studies have linked a common variant in the manganese transporter SLC39A8, p.Ala391Thr to lower blood levels of manganese. The variant has further been linked to increases in alanine transaminase levels and MRI determined hepatic inflammation. We hypothesize that the SLC39A8, p.Ala391Thr variant associates with increased risk of liver disease mediated by manganese deficiency in the general population.

**Methods:** We included n = 334,886 white participants from the UK Biobank and n = 117,074 white participants from the Copenhagen City Heart Study and the Copenhagen General Population Study combined. We tested associations with biochemical and imaging markers of liver disease, risk of ICD-based liver disease, and risk of liver-related and all-cause mortality for carriers of the SLC39A8, p.Ala391Thr variant.
Results: There were 56,705 heterozygous and 2,079 homozygous carriers of the p.Ala391Thr variant in total. The variant associated with increased plasma alanine transaminase, aspartate transaminase, and triglycerides and with lower levels of albumin, total cholesterol, and HDL cholesterol. In the Copenhagen cohort, the variant associated with increased risk of hepatocellular carcinoma (odds ratio = 1.89, 95% confidence interval (CI): 1.19-2.98, P = 0.006). Heterozygous carriers had an increased risk of liver related mortality with a hazard ratio of 1.68 (95% CI: 1.13-2.48, P = 0.007).

Conclusion: SLC39A4 p.Ala391Thr associated with increased liver enzymes and increased risk of developing and dying from liver cancer in the general population.

Telomere length and risk of cirrhosis and liver cancer in the Danish general population

Helene Gellert-Kristensen1, 3, Stig E. Bojesen2, 3, Anne Tybjærg-Hansen1, 4, Stefan Stender1, 3
1University Hospital Copenhagen, Copenhagen, Denmark, 2Department of Clinical Biochemistry, Herlev and Gentofte Hospital, Herlev Danmark, 3Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark

Background: Inherited short telomeres are associated with risk of liver disease, whereas longer telomeres predispose to cancer. The association between telomere length and risk of hepatocellular carcinoma and cholangiocarcinoma remains unknown.

Method and Results: We measured leukocyte telomere length using multiplex PCR in 63,272 individuals from the Danish general population. Telomere length and plasma alanine transaminase concentration were not associated (β = 4 x 10⁻⁶; P-value = 0.06) in a linear regression model. We tested the association between telomere length and risk of cirrhosis, hepatocellular carcinoma, and cholangiocarcinoma using Cox regression. During a median follow-up of 11 years, 241, 76, and 112 individuals developed cirrhosis, hepatocellular carcinoma, and cholangiocarcinoma, respectively. Telomere length and risk of cirrhosis were inversely and linearly associated (P-value = 0.004, P for nonlinearity = 0.27). Individuals with telomeres in the shortest vs. longest quartile had a 2.25-fold higher risk of cirrhosis. Telomere length and risk of hepatocellular carcinoma were nonlinearly associated (P-value = 0.009, P-value for nonlinearity = 0.01). This relationship resembled an inverted J-shape, with the highest risk observed in individuals with short telomeres. Individuals with telomeres in the shortest vs. longest quartile had a 2.29-fold higher risk of hepatocellular carcinoma. Telomere length was inversely and linearly associated with the risk of cholangiocarcinoma (P-value = 0.03, P for nonlinearity = 0.95). Individuals with telomeres in the shortest vs. longest quartile had a 1.86-fold higher risk of cholangiocarcinoma.

Conclusion: Shorter telomere length is associated with a higher risk of cirrhosis, hepatocellular carcinoma, and cholangiocarcinoma.

Global, regional, and country-level estimates of new HCV infections attributed to injection drug use

Adelina A Artenie1, Katharine J Looker1, Jack Stone1, Aaron G Lim1, Adam Trickey1, Anna McNaughton1, Hannah Fraser1, Matthew Hickman1, Louisa Degenhardt2, Jason Grebely3, Daniel Low-Beer4, Greg Dore4, Niklas Luhmann4, Samantha Colledge2, Peter Vickerman2
1University of Bristol, Bristol, UK, 2National Drug and Alcohol Research Centre, Sydney, Australia, 3The Kirby Institute, UNSW Sydney, Sydney, Australia, 4World Health Organization, Geneva, Switzerland

Background: We estimated, at country/regional/global levels, HCV incidence in people who inject drugs (PWID) and the number of new annual HCV infections attributed to injection drug use using multiple methods and data.

Method: We compiled previously published estimates of HCV incidence in PWID from our global systematic review and modelling studies with new estimates. We used four different methods to estimate HCV incidence: (i) longitudinal re-testing of people-at-risk or assays for recent infection (direct), (ii) dynamic modelling using HCV Ab prevalence in PWID (modelled (M1)), (iii) force-of-infection modelling using HCV Ab prevalence by injecting duration (modelled (M2)), and (iv) imputation based on HCV Ab prevalence (imputed). Country-specific HCV incidence in PWID was estimated by pooling direct, modelled M1 and M2 estimates, as available; alternatively, we used imputed estimates. Number of new annual HCV infections attributed to injection drug use was estimated by multiplying country-specific HCV incidence with number of RNA-Pсид).

Results: We included 247 HCV incidence estimates from 105 countries, representing 88% of the global PWID population. 66, 79, 88 and 14 of these estimates were direct, modelled (M1), modelled (M2) and imputed, respectively. HCV incidence ranged as 0.5-40.5/100 person-years. We estimated 1,193,660 (95% CI: 710,350-1,917,410) new HCV infections due to injection drug use annually, with variation regionally (Table) and by country (Figure). The largest number of new infections were in the US (325,230; 95% CI: 170,980-561,120; 27%), China (299,780; 95% CI: 203,290-424,160; 25%) and Russia (95,570; 95% CI: 67,400-132,860; 8%).

Conclusion: Unsafe injecting practices among PWID contribute substantially to incident HCV infections globally.

Abstract Submission No. 101632

The creation of a hepatocellular cancer (HCC) registry in a low-to-middle income country (LMIC)

Beatrice J Tiangco1, 2, 3, Shanaia Esthelle Joy P Daguit3, Ethel Dominique E Viray3, Ramonito B Nuique4, Edhel S Tripon4
1University of the Philippines National Institutes of Health, Manila, Philippines, 2Augusto P. Sarmiento Cancer Institute, The Medical City, Pasig Philippines, 3Cancer CARE Registry and Research Philippines Foundation, Inc, Pasig Philippines, 4Center for Liver Health and Transplant, The Medical City, Pasig Philippines, 5Ateneo School of Medicine and Public Health, Pasig Philippines

Background: Hepatocellular cancer (HCC) usually develops on top of chronic liver disease from various etiologies. A registry gathers real-world data on the effects of underlying risk factors, viral serologies, diagnostic imaging, and treatment on patient outcomes and helps guide screening recommendations and public policy.

Methods: Patients with HCC from the “Early Cancer Detection in the Liver of Filipinos with Chronic Active Hepatitis B using AI-Driven Integration of Clinical and Genomic Biomarkers (CANDLE) Study” were included. Follow-up was done every 6 months for three years or until study-end in March 2023. De-identified data was entered into an electronic database which served as the HCC registry.

Results: From December 2019 to January 2023, the CANDLE Study included 87 patients with HCC, 72.4% were male and majority
belonged to the lowest strata of income. On underlying liver disease: 51.7% were HbsAg+, 24.1% were HBSAg- and AntiHBC+, and NAFLD was present in 62.1%. Cirrhosis was present in 71.3%. HCC was diagnosed at an unresectable stage (BCLC B-D) in 59 (67.8%) patients, 21 (24.6%) received curative intent hepatectomy and only 46.0% received specific cancer treatment. 34 deaths were documented within the study and of these 82.4% died within 6 months of follow up.

**Conclusion:** HCC registries containing epidemiologic data such as disease etiology and host metabolic and socioeconomic factors can be interrogated by researchers for more understanding leading to better outcomes of this disease.

**Risk factors for short outcomes after EGVB: a follow-up study of 243 elder cirrhotic patients**

Yanglan He1, Qi Li1, Lingna Lv1, Chunlei Fan1, Huiguang Ding1

1Capital Medical University Youan Hospital Beijing China

**Background:** Evidence of short-term outcomes after esophagealvarical bleeding (EGVB) in the elderly cirrhotic patients is scarce. The study aimed to evaluate the 6-week rebleeding rate and mortality and explore their risk factors in elderly cirrhotic patients with acute variceal bleeding.

**Methods:** Two hundred and forty-three elderly cirrhotic patients without hepatocellular carcinoma admitted to the department of emergency with EGVB were included.

**Results:** Twenty three patients (23/237, 9.7%) developed rebleeding and 17 (17/243, 7.0%) patients died after admission. Compared to patients without rebleeding, patients with 6-week rebleeding had significantly lower diastolic blood pressure (DBP), higher troponin I (TnI) level, MELD score and Child-Pugh score. Compared to survival patients, the patients who died within 6 weeks had significantly lower systolic pressure, higher levels of myoglobin (MYO) and TnI, higher MELD and Child-Pugh scores, and higher shock index and 6-week rebleeding rate. After adjusting for MELD, DBP remained an independent risk factor for rebleeding (OR=0.951, p<0.05). After adjusting for 6-week rebleeding and MELD and Child-Pugh scores separately, MYO (OR=30.654, p<0.05) remained an independent risk factor for mortality. After adjusting for MELD score, shock index remained an independent risk factor for mortality.

**Conclusion:** Physical signs, including blood pressure and heart rate, and myocardial injury often suggest poor short-term prognosis in elderly cirrhotic patients.
hepatitis (7.6%), primary biliary cholangitis (4.0%) and drug induced liver injury (1.2%). Percentage of liver biopsies for HBV remained stable and that of HCV has decreased, whereas NAFLD and autoimmune liver diseases had rising percentages through years (Figure 2). There was no initial clinical diagnosis in 10.9% of patients, in whom liver biopsy was also mostly nonspecific (72%). However, NAFLD and autoimmune liver diseases were diagnosed in respectively 9.5% and 8.9% of these patients after biopsy.

**Conclusion:** While chronic hepatitis B infection remains most common diagnosis after liver biopsies, there were gradually increasing trends for autoimmune liver diseases and NAFLD during last decade.

The phylogenetic and geospatial approach for Hepatitis B Virus genotypes distribution in Indonesia

Sri Jayanti1, Turyadi Turyadi1, Nu’man AS Daud2, Luthfi AM Parewangi3, Rini R Bachtiar2, Rina Masada4, Irdan Handayani4, Agustiningish Agustiningish5, Korri E El-Khobar6, Muhammad N Massi7, David H Muljono8, Caecilia HC Sukowati9

1Eijkman Research Center for Molecular Biology, National Research and Innovation Agency of Indonesia Cibinong Indonesia, 2Department of Internal Medicine, Faculty of Medicine, Hasanuddin University Makassar Indonesia, 3Department of Pathology Anatomy, Hasanuddin University Makassar Indonesia, 4Department of Clinical Pathology, Faculty of Medicine, Hasanuddin University Makassar Indonesia, 5Department of Microbiology, Faculty of Medicine, Hasanuddin University Makassar Indonesia, 6Faculty of Medicine and Health, University of Sydney New South Wales Australia, 7Liver Cancer Unit, Italian Liver Foundation ONLUS Trieste Italy

The genetic landscape of Hepatitis B Virus (HBV) is intricate and exhibits geographical variations, with clinical implications and treatment responses linked to specific HBV genotypes. Despite the identification of predominant genotypes in previous studies, a comprehensive geospatial assessment of hepatitis B genotypes in Indonesia is notably absent. This underscores the urgency for extensive investigations into the burden of hepatitis B categorized by genotype in various regions. We examined the regional molecular epidemiology of the HBV genotype using a combined phylogenetic and geospatial approach. A hundred and ninety-three HBV samples were isolated from chronic hepatitis B patients and their clinical data were obtained from two distant regions, DKI Jakarta and South Sulawesi, representing western and eastern parts of Indonesia, respectively. HBV genotype was determined from DNA sequences of the S gene of HBV DNA subjected to phylogenetic analysis using standard reference sequences. Patients’ data were characterized according to demographics, genotype likelihood phylogeny, and geospatial hotspot analysis using Getis-Ord Gi* statistics. Demographic data showed that HBV isolates from DKI Jakarta were distributed by genotype B while South Sulawesi was genotype C (p<0.001). Geospatial analyses revealed a more concentrated focus on genotype C in the northern part of DKI Jakarta compared to B. Meanwhile, the distribution of HBV genotypes B and C in South Sulawesi was largely distributed across the region. This early study indicates the distinct pattern in hepatitis B molecular epidemiology and the need for a comprehensive study on the geospatial distribution of HBV genotypes in Indonesia.

Targeting CDK5/PAK1 attenuates lipid overload-induced HCC via suppressing lysosomal stress

Tongguo Miao1, Yuenan Nan1, Dong Ma2, Ying Zhang1, Xianzhe Lou2, Weivei Guan1, Lu Li1, Xiwei Yuan1

1Department of Traditional and Western Medical Hepatology, Hebei Medical University Third Hospital & Hebei International Joint Research Center for Liver Cancer Molecular Diagnosis, Hebei International Science and Technology Cooperation Base Shijiazhuang, 2Department of Biochemistry and Molecular Biology, Key Laboratory of Neural and Vascular Biology, Ministry of Education, Hebei Medical University Shijiazhuang China

**Background:** Immunotherapy has revolutionized cancer treatment. Unfortunately, most tumor types do not respond to immunotherapy due to a lack of enhancing inflammation in tumor microenvironment (TME), a contributing factor is lysosomal stress (LS). How LS impacts the TME remains understudied.

**Methods:** We investigated the role of the CDK5/PAK1 pathway in the regulation of lysosomal stress in hepatocellular carcinoma (HCC) development by conducting metabolomic analysis, gene expression profiling and immunohistochemistry analyses in RAW264.7 cells, oncogene-induced HCC mouse models and human HCC samples.

**Results:** We show that ox-LDL activates cyclin-dependent kinase 5 (CDK5), and CDK5 phosphorylates P21 (RAO1) Activated Kinase 1 (PAK1), which leads to LS. Furthermore, we found targeting of the CDK5/PAK1 pathways is a novel and tolerable approach to significantly reverse M2 transition to inhibit tumor development in vitro experiment. This approach reduced IL-10 and TGF-β expression of macrophages and suppressed ox-LDL-induced LS, together with decreasing deposition of lipofuscin and increasing expression and nuclear localization of TFEB, an indicator of LS.

**Conclusions:** This study suggests that CDK5/PAK1 pathway inhibition is a potential approach to broaden immunity therapies by suppressing lipid overload-mediated, LS-dependent M2 transition and supports the translation of this novel approach to further improve response rates for proliferation and metastatic hepatocellular carcinoma.

TERT upregulation promotes cell growth via degradation of p21 and enhances hepatocarcinogenesis

Masako Mishima1, Haruhiko Takeda1, Atsushi Takai2

1Department of Gastroenterology and Hepatology Graduate School of Medicine, Kyoto University Kyoto Japan

**Background:** Telomerase reverse transcriptase (TERT) gene aberration is detectable in more than 80% of the cases with hepatocellular carcinoma (HCC). Although TERT reactivation is essential for cellular immortalization because it stabilizes telomere length, the role of TERT in hepatocarcinogenesis remains unelucidated. This study aimed to elucidate the significance of aberrant TERT expression in hepatocytes in inflammation-associated hepatocarcinogenesis.

**Method:** We generated a mouse model with hepatocyte-specific Tert overexpression (Alb-Cre;TertTg) and examined their phenotype under chronic inflammation. Based on the transcriptome data from the liver tissue of Alb-Cre;TertTg mice, we examined the role of TERT in hepatocarcinogenesis in vitro. We also evaluated the relationship between TERT and cell cycle-related molecules, including p21, in HCC samples.

Abstract Submission No. 100166
O-0521
Result: The liver tumor development rate was increased by Tert overexpression during chronic inflammation, especially in the absence of p53 function. Gene set enrichment analysis of liver tissues revealed that gene sets related to cell cycle and apoptosis were upregulated in Alb-Cre;TertTg liver. It was found that TERT formed protein complexes with p21, cyclin A2, and cyclin E, promoted ubiquitin-mediated degradation of p21, specifically in the G1 phase. In the clinical HCC samples, TERT was highly expressed but p21 was conversely downregulated, and TERT expression was associated with the upregulation of molecules related to the cell cycle.

Conclusion: The aberrant upregulation of TERT promoted cell cycle progression via ubiquitin-mediated degradation of p21 and enhanced hepatocarcinogenesis.

Integrated multiomics reveal clinical correlation between circPTK2 and liver transplantation for HCC

Xin Hu1,2, Ronggao Chen3, Guannong Chen2, Yingchen Huang2, Di Lu, Xuyong Wei2, Qiang Wei1, Xiao Xu1,2
1Zhejiang University School of Medicine Hangzhou China, 2Key Laboratory of Integrated Oncology and Intelligent Medicine of Zhejiang Province Hangzhou China, 3Department of Hepatobiliary and Pancreatic Surgery, Affiliated Hangzhou First People’s Hospital, Zhejiang University School of Medicine Hangzhou China

Background: Circular RNAs (circRNAs)-mediated post-translational modification of RNA-binding proteins (RBP) plays a pivotal role in recurrence and metastasis of liver transplantation (LT) for hepatocellular carcinoma (HCC). However, the specific mechanism and potential clinical significance remain vague.

Methods: Patient derived tumor xenograft, organoids and the multi-omics approaches combining of transcriptome sequencing, tandem mass tag-based proteome sequencing and high-throughput sequencing were performed to screen the potential circRNAs. Tissue microarrays of LT for HCC containing 269 patients were used to evaluate the prognostic capacity of circRNAs and nucleolin (NCL).

Results: CircPTK2 was evaluated in HCC and was found to prevent the interaction between nucleolin (NCL) and the E3 ligase tripartite motif-containg 21 to reduce the proteasome-mediated degradation of NCL via K48-linked polyubiquitylation, promoting metastasis. Higher expression of circPTK2 and NCL in tumor portended worse overall survival (OS) and recurrence free survival (RFS) (RFS rat: 41.3% vs. 55.4%, P=0.0081, 37.4% vs. 63.1%, P<0.0001). CircPTK2 and NCL had satisfactory evaluation capabilities for OS in patients who beyond the Milan criteria (p=0.0034 and 0.0033). In patients who met Hangzhou’s criteria, elevated circPTK2 and NCL expression was correlated to a worse OS and RFS (OS: P=0.0048 and 0.0013, RFS: P=0.0374 and 0.0001). Notably, patients with negative AFP and low circPTK2 expression had a superior OS than those with negative AFP but high circPTK2 expression (P=0.0386).

Conclusion: CircRNA and NCL are closely related to the metastasis of HCC and are effective prognostic indicators to patients with LT for HCC.

Intra-tumoral Microbiome Promotes Hepatoma Cell Proliferation and Is Associated with Prognosis

Ming-Lun Yeh1, Yi-Shan Tsai1, Po-Cheng Liang1, Po-Yau Hsu1, Ting-Yuan Jang1, Yu-Wu We1, Zu-Yau Lin1, Chung-Feng Huang1, Jee-Fu Huang1, Chia-Yen Dai1, Wan-Long Chuang1, Ming-Lung Yu1
1Hepatobiliary Division, Department of Internal Medicine, Kaohsiung Medical University Hospital Kaohsiung Taiwan, 2School of Medicine, College of Medicine and Center of Excellence for Metabolic Associated Fatty Liver Disease, National Sun Yat-sen University Kaohsiung Taiwan

Background: Cancer specific intra-tumoral microbiome had been identified. We aimed to explore the role of intra-tumoral microbiome in the pathogenesis of HCC.

Methods: The method to harvest primary hepatoma cells had been reported previously. Microbiome infiltration in more than 20% of areas under HPF was defined as abundant. Fluorescence in situ hybridization (FISH) was performed with bacterial 16s RNA sequences in fresh HCC surgical tissues. Taxonomic compositions were analyzed by 16s rRNA sequencing. Hepatoma cell lines (Huh7, HA22T and Hep3B) cell line were cultured with microbiome medium for cell proliferation experiments. Metabolomic study was done by liquid chromatography-tandem mass spectrometry.

Results: FISH confirmed the presence of intra-tumoral microbiome in HCC. The most dominant microbe at the phylum level was Proteobacteria, and Xanthomonas, and Acetobacter were the most dominant microbes at the genus level. It showed no significant differences in the taxonomic compositions in different HCC stages and etiologies. HCC patients with abundant microbiome demonstrated a larger tumor size and decreased survival. The cell proliferation experiments by WST1 assay showed hepatoma cells cultured with medium of microbiome showed a higher cell proliferation and the effect diminished after removal of microbiome. These cells exhibited higher expression levels of YAP1, and the YAP1 expression decreased after removal of microbiome. The untargeted metabolomic study demonstrated a significantly difference of metabolites before and after the removal of microbiome. The targeted metabolomic study demonstrated a significantly difference of metabolites before and after the removal of microbiome.

Conclusions: Intra-tumoral microbiome promotes hepatoma cell proliferation through Hippo-YAP pathway, and was associated with a poor survival. The results implicated a therapeutic target of HCC.

Whole-genome sequencing-based mutational analysis on hypovascular small hepatocellular carcinoma.

Haruhiko Takeda1, Atsushi Takai1, Tadashi Inuzuka1, Etsuro Hatano2, Hiroshi Seno1, Masayuki Ueno1, Yosuke Fuji1, Shigeharu Nakano1, Masako Mishima1, Eriko Iguchi1
1Department of Gastroenterology and Hepatology, Kyoto University Hospital Kyoto Japan, 2Department of Surgery, Kyoto University Hospital Kyoto Japan

Background: Whole-genome sequencing (WGS) is a powerful tool to unveil the genetic landscape of individual tumors. Although WGS has been revealed the mutational landscape of classical HCCs, genetic feature of hypovascular small liver nodules remains still unclear.

Methods: We conducted multi-regional WGS on a total of 41 samples including sixteen surgically resected hypovascular tumor tissues, eight hypervascular HCCs, two extrahepatic metastatic lesions, seven non-tumor liver tissues and eight lymphocytes from nine HCC patients. We comparatively analyzed the genetic alterations, including point mutations, genetic structural variations and copy number variations of hypovascular liver tumor tissues, with hypervascular HCC tissues and also fifteen Japanese patients with advanced HCC with portal vein
invasion in LIRI-JP cohort of International Cancer Genome Consortium project.

Results: All the hypovascular nodules were pathologically revealed well to mod differentiated HCCs, which harbored approximately 8000 mutations including single nucleotide variants and short indels along with several structural variations such as chromosomal translocations, inversions and arm-level amplifications or heterozygous alterations. Importantly, these genetic alterations included several well-known cancer driver genes as well as hypervascular HCCs. As for the structural variations, advanced HCC with portal invasion had significantly more numbers of genomic rearrangements than hypovascular HCC tissues, suggesting the genetic alterations should be formed more complicated during multistep hepatocarcinogenesis from hypovascular HCCs to invasive HCCs.

Conclusions: Small hypovascular HCCs already accumulate various genetic alterations including driver gene mutations of HCC. Genetic comparison with the earlier stage noncancerous liver nodules should be useful for the understanding of the initial step of hepatocarcinogenesis.

Low-speed regular exercise reduces HCC development by muscle PGC1α-mediated kynurenine degradation

Naoko Ohtani, Vu thuong Huyen, Ryota Yamagishi, Kanae Echizen, Yoshihiko Nonaka, Shinji Fukuda

1Osaka Metropolitan University, Graduate School of Medicine Osaka Japan, 2Institute for Advanced Biosciences, Keio University Tsuruoka Japan

Recently, the number of patients with steatohepatitis-associated hepatocellular carcinoma (HCC) has been steadily increasing. The beneficial effects of exercise on cancer prevention have been generally accepted; however, the mechanisms remain largely unclear. In this study, we subjected mice to chemical liver carcinogenesis protocol with a continuous high-fat diet feeding for 35 weeks and subsequent low-speed (10m/min), one-hour regular running everyday for the last 8 weeks in the protocol. Interestingly, the exercised mice developed significantly reduced number of HCC. The metabolome analysis using mouse serum revealed that kynurenine, a well-known onco-metabolite that can act on AhR nuclear receptor to suppress antitumor immunity, significantly decreased in the exercised mice. In the exercised group, the expression of genes encoding PGC-1α and PGC-1α-dependent kynurenine aminotransferases (KAT), which can degrade kynurenine, significantly upregulated in the skeletal muscles, coinciding with the HCC reduction. These results suggest that the upregulation of skeletal muscle-derived PGC-1α and KAT by exercise could activate anti-tumor immunity by degrading kynurenine. To this end, using the liver tumor tissue, we performed mRNA-sequencing and WGCNA (Weighted Gene Correlation Network Analysis), and successfully identified a series of gene-set modules altered in parallel by exercise. Interestingly, certain gene-set modules were associated with the reduction of Treg cells and tumor vascularity by exercise, indicating that exercise ameliorated the tumor microenvironment. We confirmed these modules are also reduced by AhR inhibitor treatment in mice, suggesting that these alterations are kynurenine-AhR signaling-dependent. Our analysis shows that low-speed exercise has beneficial inter-organ effects for significant HCC prevention.

Development of precision-bioprinted patient-derived organoids for high-throughput drug screening

Janina EE Tirtzin-Parker, Gayatri D Shirolkar, Sara Pasic, Jonathan Tibballs, Shirley Go, Rachel Way, Michael Wallace, Louise Winteringham, Peter Leedman, Benjamin J Dwyer

1Curtin University Bentley - Perth Australia, 2Harry Perkins Institute of Medical Research Perth Australia, 3Liver Cancer Collaborative Perth Australia

Background and Aims: Liver cancer, the third most common cause of cancer mortality globally, is inadequately addressed by current systemic treatments due to limited efficacy and high toxicity. New targeted therapies are essential. The development of such therapies is hindered by the lack of suitable in vitro models. This study explores the use of patient-derived organoids (PDOs), potentially superior to traditional models, employing Inventia Life Science’s defined bio-inks in a RASTRUM™ bio-printer for better simulation of the tumour microenvironment.

Methods: We processed 50 liver cancer samples (47 HCC, 3 CCA) to create PDOs in Cultiex Basement Membrane Extract (BME2) and Inventia’s defined bio-inks. The RASTRUM™ bio-printer was employed, utilising bio-inks with stiffnesses of 1.1 or 3 kPa, to identify the best substrate for PDO growth, assessed via imaging and assays. Drug reactions were analysed in PDOs compared to hepatocyte cell lines across matrices.

Results: Eighteen PDO lines were established. Pre-defined matrices enhanced PDO growth, and successful lines were bio-printed for drug assays. The 3 kPa bio-ink was optimal for PDO growth and suitable for 384-well high-throughput assays, revealing significant matrix-dependent drug responses.

Conclusion: A biobank for primary liver cancer PDOs was developed for drug screening. With Inventia Life Sciences, we introduced high-throughput, precision-bioprinted PDO models for primary liver cancer, enhancing drug screening and paving the way for innovative liver cancer treatment development.

Alpha-mangostin nanoparticles exerts hepatocellular carcinoma via alteration of PI3K/Akt pathway

Vikas Kumar

1AAI-DU Allahabad India

Background: Hepatocellular carcinoma (HCC) is the widely documented danger to the liver and 3rd most common reason for tumor death around the world. Identification of oncogene and its related possible pathway is crucial for understanding therapy resistance and effectual treatment. Researcher targeted the 5-bisphosphate 3-kinase/protein kinase B, phosphatidylinositol-4 and mitogen activated protein kinase’s pathway to suppress the cell proliferation and expansion. We made attempt to fabrication the solid lipid nanoparticle (SLN) of alpha-mangostin and examine against the diethylnitrosamine (DEN) induced HCC and explore possible mechanism of action.

Material & method: Double emulsion solvent displacement model was used for the preparation of alpha-mangostin-SLN. Intraperitoneal injection of DEN (200 mg/kg) was used for induction the HCC and various parameters were scrutinized. The genetic effects HP-SLN on Pdk1, Akt1, Pik3r1, Map3k1, Erb2, Pik3ca using semi-quantitative RT-PCR analysis were assessed. Morphological and histopathological component of hepatic tissue were estimated.
Isolating a safe and effective method of treatment for the primary liver cancer remains a global health challenge, specifically hepatocellular carcinoma (HCC). MicroRNA (miR), a small non-coding RNA molecule, performs crucial functions in several biological processes, such as cancer growth and advancement. In this study, we investigated whether miR-29a could modulate the oncogenicity of HCC.

Methods and Materials: Serum of HCC patients and HCC tissues derived from the western diet (WD)/carbon tetrachloride (CCl4)-induced HCC animal model were collected. Transgenic mice were used to study the role of miR-29a.

Key Findings: Reduced miR-29a levels in the serum of HCC patients and the liver tissue of the wild type (WT) of a WD/CCl4-induced HCC animal model were noted. Proteomics analysis identified the pathway-centric role of miR-29a in HCC by targeting MYBL2. Human bioinformatics survey from GTEX and TCGA revealed higher expression of MYBL2 at the upstream of NOL9 in HCC cells were disclosed by bioinformatics analysis and validated by western blot, qRT-PCR, methylation PCR, and antiproliferative effect of sorafenib. The regulatory mechanisms in the upstream of NOL9 in HCC cells were established for evaluating proliferation, apoptosis, cell cycle, and antiproliferative effect of sorafenib.

Conclusion: Our collective data revealed that the ZNF384/NOL9 axis in HCC and the suppression of NOL9 might constitute a strategy for increasing the effect of sorafenib to inhibit HCC cells.

Cabozaatinib inhibits tumor growth of lenvatinib-resistant hepatoma cells in vitro and in vivo
Koji Fujita¹, Kei Takuma¹, Mai Nakahara¹, Kyoko Oura¹, Tomoko Tadokoro¹, Joji Tani¹, Asahiro Morishita¹, Masafumi Ono¹, Takashi Himoto², Tsutomu Masaki³
¹Kagawa University Takamatsu Japan, ²Kagawa Prefectural University of Health Sciences Takamatsu Japan

Background and aim: Cabozatinib is a newly developed tyrosine kinase inhibitor, which can be used to treat patients with hepatocellular carcinoma (HCC) unresponsive to conventional tyrosine kinase inhibitors, including lenvatinib. However, the efficacy of cabozatinib in lenvatinib-resistant cases has not been well established in clinical trials or basic studies. The present study aims to determine whether cabozatinib can suppress tumor growth of lenvatinib-resistant HCC cell lines in vitro and in vivo.

Methods: To establish lenvatinib-resistant hepatoma cells, Hep3B cells were cultured with different doses of lenvatinib ranging from 1 to 20 μM for three months. Cell proliferation assays were conducted using WST-8. Flowcytometry was adopted to evaluate cell cycle phase arrest and apoptotic changes. Proteome analysis of xenografts was
performed to identify tumor suppressor genes which contributed to efficacy of cabozantinib.

**Results:** Lenvatinib-resistant Hep3B cells (Hep3B-LR) exhibited approximately 20 times greater IC50 for lenvatinib than the wild type. Compared with wild-type Hep3B, Hep3B-LR was characterized by enhanced mTOR phosphorylation with the downregulation of phosphorylated Akt. Cabozantinib suppressed tumor growth in Hep3B-LR in vitro by inducing cell cycle arrest at G2 phase and apoptosis. The animal experiments validated the antitumor effect of cabozantinib. Proteome analysis demonstrated an upregulation of FDCT, a tumor suppressor gene. Knockdown of FTCD enhanced tumor growth of Hep3B-LR.

**Conclusion:** Cabozantinib inhibited the growth of Hep3B-LR in vitro and in vivo. FDCT may be a novel therapeutic target of cabozantinib in case of lenvatinib treatment failure.

**O-0532**

**IRGM is a novel regulator of PD-L1 via promoting S6K1/YBX1 axis in hepatocellular carcinoma**

**Beng Yang1, Junnan Ru1, Jian Wu1, Shusen Zheng1**

1The First Affiliated Hospital, College of Medicine, Zhejiang University Hangzhou China

**Background:** Immunity-related GTPase M (IRGM), an Interferon-inducible protein, functions as a pivotal immunoregulator in multiple autoimmune diseases and infections. However, the role of IRGM in hepatocellular carcinoma (HCC) development remains unveiled.

**Methods:** Orthotopic patient-derived xenograft (PDX) model, xenograft tumor models, IRGM-conditional knockout mice, and in vitro experiments were utilized to investigate the role of IFN-γ-induced IRGM in HCC progression. Single-cell sequencing and flow cytometry were employed to explore tumor immune environment changes. Whole gene sequencing, Immunoprecipitation-Mass spectrometry (IP-MS), and ChIP assays were performed to elucidate the underlying mechanism.

**Results:** IFN-γ robustly triggers the expression of Irgm1 in HCC. High IRGM expression in tumor samples indicated poor prognosis in HCC patients. In vivo and in vitro experiments demonstrated that IRGM facilitated the malignant phenotype of HCC. Furthermore, Inhibition of Irgm promoted the infiltration of CD8+ cytotoxic T lymphocytes (CTLs) in TME of HCC, which was ascribed to the reduction of PD-L1. Mechanistically, IRGM promotes the interaction between YBX1 and its phosphokinase p70S6K1, leading to phosphorylation of YBX1, resulting in transcription activation of PD-L1 mediated by p-YBX1. The combined application of Irgm inhibition and α-PD1 demonstrated a stronger anti-tumor immune response in HCC tumor-burden mice.

**Conclusion:** IFN-γ-induced IRGM is a novel regulator in tumor microenvironment and HCC progression. And IRGM suppresses CD8+ CTLs infiltration and function in HCC via regulating p70S6K1/YBX1/PD-L1 axis. This study may raise a novel therapeutic strategy combined with immune checkpoint inhibitors (ICIs) against HCC.

**Novel biomolecule potentiates classic therapeutic protocol against hepatocellular carcinoma**

**Amr Amin1,2**

1UAE University Al Ain United Arab Emirates, 2The University of Sharjah, College of Medicine Sharjah United Arab Emirates

**Background:** Sorafenib (SB) is a multi-kinase inhibitor and is the first line of treatment for advanced hepatocellular carcinoma (HCC), but its clinical applications are limited due to severe side effects and drug resistance. To optimize its therapeutic effects, we used here safranal (SF); a major bioactive component of saffron, to assess the development of HCC in animal model.

**Methods:** Therapeutic effect of SF alone or combined with SB was assessed in cirrhosis rat model of HCC using histopathological, biochemical, immunohistochemical and immunoblotting techniques. Transcriptome analyses were also employed to determine the therapeutic effects of SF and SB.

**Results:** Combined treatments significantly reduced the nodule multiplicity compared to a single therapy group of HCC. It also induced apoptosis, blocked proliferation, and arrested the cell cycle, in the HCC group. Combined therapy improved SB’s anti-inflammatory, anti-fibrotic, and anti-metastatic activities. Using transcriptomic analysis, 45 genes were found to be associated with HCC suppression. Those genes were associated with cellular development, oxidative stress, wound healing, and apoptosis.

**Conclusions:** Downregulation of NF-B-p65, COX-2 and β-catenin are possible mechanisms to underly SF beneficial effects. SF represents a viable candidate for pharmacological target as new anti-liver cancer treatment, both in monotherapy and combined with SB as the current gold standard therapy. Further research is necessary as the clinical safety margin and dosage of the presented combination medication have yet to be determined.

**A Novel Bile Acid-related lncRNA Signature for Predicting Prognosis and Treatment Response in HCC**

**Hao Cui1,3, Tao Han2, Baiguo Xu1,3, Huiling Xiang1, Jia Lian4, Yingtang Gao5, Zhenjun Yu3, Jingxiang Shi4**

1Department of Gastroenterology and Hepatology, The Third Central Hospital of Tianjin Tianjin China, 2Department of Gastroenterology and Hepatology, Tianjin Union Medical Center, Tianjin Medical University Tianjin China, 3Department of Gastroenterology and Hepatology, The Third Central Clinical College of Tianjin Medical University Tianjin China, 4Department of Hepatobiliary Surgery, The Third Central Hospital of Tianjin Tianjin China, 5Tianjin Key Laboratory of Extracorporeal Life Support for Critical Diseases, Tianjin Institute of Hepatobiliary Disease, Nankai University Affinity the Third Central Hospital Tianjin China

Bile acids and salts have been shown to play a role in liver carcinogenesis through DNA damage, inflammation, and tumor proliferation. However, the correlation between bile acid metabolism and hepatocellular carcinoma (HCC) prognosis remains unclear. This study aimed to identify a predictive signature of bile acid and bile salt metabolism-related long non-coding RNAs (lncRNAs) for HCC prognosis and treatment response. The study used HCC RNA-sequencing data and corresponding clinical and prognostic data from The Cancer Genome Atlas. A prognostic model consisting of five bile acid and bile salt metabolism-related lncRNAs was developed and evaluated in a training set, a validation set and an external set. The model demonstrated good performance in predicting HCC prognosis and was shown to be an independent biomarker for prognosis. Additionally, our study revealed a significant association between the signature and immune cell infiltration, as well as its predictive value for therapeutic responses to both immunotherapy and chemotherapy. Furthermore, three lncRNAs (LUCA T1, AL031985.3 and AC015908.3) expression levels in our
signature were validated through qRT-PCR in a cohort of 50 pairs of HCC patient tumor samples and corresponding adjacent non-tumor samples, along with 10 samples of normal liver tissue adjacent to benign lesions. These findings suggest that this novel bile acid and bile salt metabolism-related IncRNA signature can independently predict the prognosis of patients with HCC and may be utilized as a potential predictor of response to treatment in this setting.

Inhibition of CDK4/6 and XPO1 induces senescence with acquired vulnerability to CRBN-based PROTACs

Hui Wang1, Wenxin Qin1, Cun Wang1
1State Key Laboratory of Systems Medicine for Cancer, Shanghai Cancer Institute Shanghai China

Background: Despite the increasing number of treatment options available for liver cancer, only a small proportion of patients achieve long-term clinical benefits. Herein, we aim to develop new therapeutic approaches for liver cancer.

Methods: Compound screen was conducted to identify inhibitors that could synergistically induce senescence when combined with CDK4/6 inhibitor. The combination effects of CDK4/6 inhibitor and XPO1 inhibitor on cellular senescence were investigated in a panel of human liver cancer cell lines, mouse models of liver cancer, patient-derived organoids, and patient-derived xenografts. A senolytic-drug screen was performed to identify drugs that selectively killed senescent liver cancer cells.

Results: The combination of CDK4/6 inhibitor and XPO1 inhibitor synergistically induces senescence of liver cancer cells in vitro and in vivo. The XPO1 inhibitor acts by causing accumulation of RB1 in the nucleus, leading to decreased E2F signaling and promoting senescence induction by the CDK4/6 inhibitor. Through a senolytic-drug screen, CRBN-based PROTAC ARV-825 was identified as an agent that can selectively kill senescent liver cancer cells. Upregulation of CRBN was a vulnerability of senescent liver cancer cells, making them highly sensitive to CRBN-based PROTAC drugs. Mechanistically, we find that USP2 directly interacts with CRBN, leading to the deubiquitination and stabilization of CRBN in senescent liver cancer cells.

Conclusions: Our study demonstrates a striking synergy in senescence induction of liver cancer cells through the combination of CDK4/6 inhibitor and XPO1 inhibitor. These findings also shed light on the molecular processes underlying the vulnerability of senescent liver cancer cells to CRBN-based PROTAC therapy.

Abstract Submission No. 100260

Clinical significance of Cytokine Change in Hepatocellular Carcinoma after Radiotherapy

BAEK GYU JUN1, Sang Gyune Kim2, HeeJae Jung2
1Asanseoul clinic Seoul South Korea, 2Soonchunhyang University College of Medicine Bucheon Hospital Bucheon Korea

Background/Aim: Radiotherapy (RT) can enhance tumor immunogenicity and increases production of cytokines. Prior studies have examined change of cytokine level in cancer patients after radiotherapy, but study on hepatocellular carcinoma (HCC) is lacking. This study investigated the effects of radiotherapy on serum levels of interleukin-2 (IL-2), IL-10, IL-22 and tumor necrosis factor alpha (TNF-a) with HCC.

Methods: Data of HCC patients who underwent radiotherapy at one tertiary referral hospitals between March 2016 and December 2019 for the prospective study. This study included 20 hepatitis B virus (HBV) patients with HCC undergoing RT and 69 HBV controls. The control group was classified into three groups as follows: chronic hepatitis B (CHB) (n=20), liver cirrhosis (LC) (n=21), decompensated LC (DLC) (n=20). Cytokines were serially monitored at pre-RT, end of RT, 1 week and 4 weeks after RT.

Results: At baseline, serum mean levels of IL-6 and IL-22 were higher in patients with HCC than in controls. In control group, serum mean levels of IL-6 and IL-22 were highest in DLC group and lowest in CHB group. The mean levels of IL-6 and IL-22 were increasing early after RT. Levels of TNF-a and aminotransferase (AST) had a positive correlation over time after RT (1 week : r = 0.622 (p=0.004), 4 week : r = 0.523 (p=0.022)).

Conclusion: RT induces changes in levels of IL-6 and IL-22 in HCC patients. Expression of IL-6 and IL-22 level is correlated with liver disease severity.

SOCS1 tumor suppressor sensitizes hepatocellular carcinoma cells to oxidative stress

Subburaj ILANGUMARAN1, Akhil Shukla1, Md GM Khan1, Anny A Cayarga1, Mozhele Namvapour1, Mohammad MH Chowdury1, Sheela Ramanathan1
1University of Sherbrooke, Faculty of Medicine and Health Sciences Sherbrooke Canada

Background: The SOCS1 gene is frequently repressed in hepatocellular carcinoma (HCC). Studying the tumor suppression mechanisms of SOCS1, we have shown that SOCS1 regulates p21-dependent NRF2 activation. Here, we investigated SOCS1-mediated modulation of cellular antioxidant response in HCC cells.

Methods: Murine Hepa-1 cells expressing SOCS1 (Hepa-SOCS1) or control vector (Hepa-vector) were exposed to tert-butyl hydroperoxide (t-BHP) or cisplatin to induce oxidative stress. CDKN1A and NRF2 expression was evaluated by western blot. Induction of NRF2 target genes and proteins was assessed by RT-qPCR and immunofluorescence microscopy. Reactive oxygen species and lipid peroxidation were estimated by microscopy. Proteomes of Hepa-SOCS1 and Hepa-vector cells treated with t-BHP or cisplatin were studied by mass spectrometry.

Results: t-BHP and cisplatin upregulated CDKN1A and NRF2 proteins, and induced NRF2 target genes NfSe2L, Gclc, Gstm1, Gpx2, Hmox1 and Nqo1 and their protein products, which were markedly attenuated by SOCS1. t-BHP and cisplatin markedly reduced the survival of Hepa-SOCS1 cells, accompanied by a reduction in reactive oxygen species and lipid peroxidation, suggesting increased sensitivity of SOCS1 expressing cells to oxidative stress. Proteomic data revealed that SOCS1 modulated many proteins involved in diverse molecular pathways, including ‘chemical carcinogenesis - reactive oxygen species’ with downregulation of several proteins. GCLC, downregulated by SOCS1 at the transcript and protein levels, correlated positively with NFE2L2 and negatively with SOCS1 expression in the TCGA-LIHC dataset.

Conclusions: SOCS1 attenuates NRF2-mediated antioxidant response in HCC cells and this regulation is crucial to prevent their ability to withstand elevated oxidative stress.
Hiệu Hiệu1, Lâm Ngô2, Anh Nguyên3

**Purpose:** To research the imaging characteristics of magnetic resonance imaging (MRI) with primovist in the diagnosis of hepatocellular carcinoma (HCC).

**Material and methods:** The study was conducted on 35 patients regardless of gender, of all ages who came for examination at K Tan Trieu hospital, during the period from May 2021 to October 2022, with indication for primovist MRI and underwent a biopsy or surgery with pathologic findings.

**Results:** The rate of HCC in the study was 86%. Mean age 56.8 years old. Male/female ratio: 10,67. 77% of patients in the study had type 1 - enhanced HCC. The mean value of ADC in patients with HCC was 1.2. Most patients have a moderate differentiation of 60%. Patients with high-differentiation on histopathology mostly have type 3 enhancement. With moderate-differentiation, most have type 1 enhancement. With poorly-differentiation, all have type 1 enhancement. The ADC value in the group of patients with high-differentiation was higher than in the group of patients with moderately-differentiation and poorly-differentiation.

**Conclusion:** Primovist magnetic resonance imaging is highly valuable in the diagnosis of hepatocellular carcinoma with typical changes in ADC values.

**KEY WORDS:** Hepatocellular carcinoma (HCC), Apparent diffusion coefficient (ADC), Magnetic Resonance Imaging (MRI).

---

**MicroRNA-885-5p as a Master Regulator in Cell Cycle Progression of HCC Cells**

Chaiyaboot Ariyachet1,2, Archittapon Nakkaew1,3, Pitsit Tangkijvinich1,2
1Department of Biochemistry, Faculty of Medicine, Chulalongkorn University Bangkok Thailand, 2Center of Excellence in Hepatitis and Liver Cancer, Faculty of Medicine, Chulalongkorn University Bangkok Thailand

**Background:** MicroRNAs (miRNAs) are a class of small non-coding RNAs that regulate specific messenger RNAs (mRNAs) by inhibiting mRNA translation and stability. Emerging studies have demonstrated dysregulation of various miRNAs in the development of hepatocellular carcinoma (HCC). In this study, we aim to identify a novel tumor suppressor miRNA and dissect its molecular functions in HCC cells.

**Methods:** Three microRNA gene profiles of HCC tissues from the TCGA and GEO databases were analyzed to identify putative tumor suppressor miRNAs. MiRNA-885-5p (miR-885-5p) was chosen for functional tests, including MTT assay, BrdU incorporation, and cell cycle analysis, in three HCC cell lines. Transcriptional profiling of control and miR-885-5p-overexpressing HCC cells was performed to identify potential targets of miR-885-5p. Dual luciferase assays were conducted to confirm the direct interaction between miR-885-5p and its target mRNAs.

**Results:** Analysis of miRNA expression profiles from three normal and HCC tissue pairs identified nine miRNAs commonly downregulated in HCC tissues, including miR-885-5p. Overexpression of miR-885-5p significantly suppressed proliferation of HCC cells. Transcriptional profiles of these HCC cells revealed that miR-885-5p induced downregulation of several key genes that promote the G1-to-S transition, including CDK6, E2F2, and CCNA2. Accordingly, miR-885-5p-overexpressing cells displayed reduced rates of BrdU incorporation and G1 phase arrest in the cell cycle. Finally, dual luciferase assays confirmed the direct interaction of miR-885-5p with 3’ untranslated regions of CDK6, E2F2, and CCNA2 transcripts.

**Conclusions:** MiR-885-5p inhibits G1-to-S progression in HCC cells and may represent a new target for HCC therapy.
Background: The efficacy of the combination immunotherapy of atezolizumab and bevacizumab (Atezo+Bev), the first-line systemic therapy for unresectable hepatocellular carcinoma (uHCC), varies from patient to patient. Therapeutic biomarkers might help improve patient outcomes of Atezo+Bev therapy for uHCC. This study aimed to evaluate the status and dynamics of peripheral T cell subpopulations in uHCC patients receiving Atezo+Bev treatment and to explore biomarkers predictive of therapeutic response.

Methods: 83 uHCC patients who initiated Atezo+Bev treatment at our hospital between October 2020 and June 2022 were enrolled. Peripheral T cell subpopulations in peripheral blood mononuclear cells (PBMCs) at baseline and at 3 weeks post-treatment were investigated using flow cytometry. The association between peripheral T cell subpopulation profiles and clinical outcomes was analyzed.

Results: Baseline peripheral T cell subpopulations could be profiled in 70 patients with sufficient cell counts, among which 3-week subpopulations could be evaluated in 51 patients. Multivariate analysis revealed that a high baseline proportion of CD8+ central memory T (T(CM)) cells was independently associated with longer progression-free survival (PFS). Further, overall survival (OS) was significantly prolonged in patients with increased CD8+ effector memory T (TEM) cell proportions after the initiation of Atezo+Bev treatment.

Conclusions: TCM proportion at baseline might be a good indicator of the efficacy of Atezo+Bev therapy. In addition, observation of increasing TEM cell proportions might be an early predictor of the potential clinical benefits of treatment.

Molecular Changes of Circulating Tumor Cells in HCC Patients Receiving Atezolizumab plus Bevacizumab

Yosuke Murata1,2, Takuto Nosaka1, Yasunari Nakamoto1
1Second Department of Internal Medicine, University of Fukui FUKUI JAPAN, 2Sugita Genpaku Memorial Obama Municipal Hospital FUKUI JAPAN

Background: Mechanisms leading to cancer progression of Hepatocellular Carcinoma (HCC) during immunotherapies remain unclear. Circulating tumor cells (CTCs) are non-invasive and real-time biomarkers that provide information about metastatic processes. CTC analysis could reveal molecular mechanisms of cancer progression. We investigated changes in CTC counts and gene expression related to cancer progression in HCC patients treated by Atezolizumab plus Bevacizumab (Atezo/Bev).

Methods: We obtained peripheral blood from 19 HCC patients treated by Atezo/Bev at baseline and response evaluation. Treatment response was assessed by modified RECIST. CTCs were isolated with RosetteSep™ and stained with antibodies targeting CD45 and PanCK. CD45 negative and PanCK positive cells by flow cytometry were defined as CTCs. The expression of 373 genes in CTCs were investigated by next-generation sequencing (NGS) and qRT-PCR.

Results: CTC counts of PR/SD group decreased at response evaluation, compared with baseline (192 vs.94, p<0.01). In NGS analysis, 99 genes showed significant expression changes in clinical course. Unsupervised hierarchical clustering of 99 genes classified into two clusters A and B. Patients in cluster A were responder and showed 100.0% survival rate at 1-year, which was better than 50.0% in cluster B. Apoptosis pathway was upregulated in responder (cluster A). Furthermore, TGF-beta pathway-related genes such as ACT1, CDKN1B and IKBKB were upregulated in non-responder (cluster B) (p<0.05).

Conclusion: The change of CTC counts correlated with therapeutic effect and TGF-beta pathway may play an important role in resistance to Atezo/Bev. CTC analysis in HCC patients during immunotherapy could reveal molecular mechanisms of cancer progression.

Multiple omics revealed the clinical correlation between circPTK2 and liver transplantation for HCC

Xiu Hu1,2, Ronggao Chen1, Guanrong Chen1, Yingchen Huang1, Di Lu1, Xuyong Wei2, Qiang Wei3, Xiao Xu1,4
1Zhejiang University School of Medicine Hangzhou China, 2Key Laboratory of Integrated Oncology and Intelligent Medicine of Zhejiang Province Hangzhou China, 3Department of Hepatobiliary and Pancreatic Surgery, Affiliated Hangzhou First People’s Hospital, Zhejiang University School of Medicine Hangzhou China

Background: Circular RNAs (circRNAs)-mediated post-translational modification of RNA-binding proteins (RBP) plays a pivotal role in recurrence and metastasis of liver transplantation (LT) for hepatocellular carcinoma (HCC). However, the specific mechanism and potential clinical significance remain vague.

Methods: Patient derived tumor xenograft, organoids and the multi-omics approaches combining of transcriptome sequencing, tandem mass tag-based proteome sequencing and high-throughput sequencing were performed to screen the potential circRNAs. Tissue microarrays of LT for HCC containing 269 patients were used to evaluate the prognostic capacity of circRNAs and nucleolin (NCL).

Results: CircPTK2 was evaluated in HCC and was found to prevent the interaction between nucleolin (NCL) and the E3 ligase tripartite motif-containing 21 to reduce the proteasome-mediated degradation of NCL via K48-linked polyubiquitylation, promoting metastasis. Higher expression of circPTK2 and NCL in tumor tissue portended worse overall survival (OS) and recurrence free survival (RFS) (RFS: 41.3% vs. 55.4%, P=0.0081, 37.4% vs. 63.1%, P<0.0001). CircPTK2 and NCL had satisfactory evaluation capabilities for OS in patients who beyond the Milan criteria (p=0.0034 and 0.0033). In patients who met Hangzhou’s criteria, elevated circPTK2 and NCL expression was correlated to a worse OS and RFS (OS: P=0.0048 and 0.0013, RFS: P=0.0374 and 0.0001). Notably, patients with negative AFP and low circPTK2 expression had a superior OS than those with negative AFP but high circPTK2 expression (P=0.0386).

Conclusion: CircRNA and NCL are closely related to the metastasis of HCC and are effective prognostic indicators to patients with LT for HCC.

Mitochondria-targeted Icaritin Induces Immune-Genic Cell Death in Hepatocellular Carcinoma

Siyu Chen1,2, Xiao Xu1,2, NaSha Qi1,2,3,4
1Hangzhou, Zhejiang Province Hangzhou China, 2Zhejiang University, School of Medicine Hangzhou China, 3Key Laboratory of Integrated Oncology and Intelligent Medicine of Zhejiang Province Hangzhou China, 4Zhejiang Chinese Medicine University Hangzhou China

Background: Icaritin (ICT), a novel small molecule from traditional Chinese medicine, induces mitophagy and immunogenic cell death (ICD), showing promise for treating advanced unresectable hepatocellular carcinoma. However, its limited bioavailability restricts clinical
use. We developed amphiphilic copolymer-encapsulated icariin nanoparticles (Icaritin NPs) with mitochondrial targeting to improve its bioavailability, tumor-targeting, and anti-cancer immunogenicities. **Method:** We synthesized a novel mitochondrial targeting amphiphilic copolymer OPDEA-PCL and self-assembled it with ICT into micelles, using polyethylene glycol-polyacrylate (PEG-PCL) as a positive carrier. Confocal imaging and flow cytometry were utilized to analyze cellular uptake of OPDEA-PCL/ICT nanoparticles. In a mouse subcutaneous HCC model, free ICT, PEG-PCL/ICT, and OPDEA-PCL/ICT NPs were intravenously administered to tumor-bearing mice to evaluate their anti-tumor effects. **Results:** OPDEA-PCL/ICT had an optimal ~140 nm particle size, 0.19 PDI, and 86% encapsulation efficiency. It rapidly internalized into H22 cells, targeting mitochondria. Post-intravenous injection, in vivo imaging revealed effective tumor accumulation. The tumor inhibition rate was 47%. Flow cytometry showed post-treatment, de activation, increased cytoxic CD8+ T cells, and decreased immunosuppressive Tregs and MDSC in tumor tissues. Blood, liver, and kidney indices showed no adverse reactions. **Conclusion:** OPDEA-PCL efficiently encapsulates icariin into mitochondrial-targeted nanoparticles, significantly boosting icariin’s bioavailability. This process amplifies mitophagy, inducing immunogenic cell death (ICD) and activating the immune microenvironment in HCC tumors, thereby achieving potent tumor suppression.

**Targeting XPO1 inhibits proliferation of hepatocellular carcinoma cells by disrupting redox balance**

Linmeng Zhang1, Wei Wang1, Cun Wang2
1Laboratory of Systems Medicine for Cancer, Shanghai Cancer Institute, Renji Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai 200032, China; Shanghai China
2Department of Global Medical Research Promotion, Shinshu University School of Medicine, Matsumoto Japan

**Background:** Hepatocellular carcinoma (HCC) poses a significant threat to public health due to its complex pathological mechanism and poor prognosis. There is an urgent need to identify efficient targets and effective treatment strategies for HCC. **Methods:** By analyzing public liver cancer databases, we found XPO1, an essential gene of liver cancer, was aberrantly expressed in the HCC and associated with poor survival. The effect of XPO1 inhibitor was investigated in cell lines and mouse models of HCC. A resistance screen was performed to identify the key gene in the drug resistance. To identify inhibitors that could synergistically function with XPO1 inhibitor, a compound screen was conducted. **Results:** XPO1 inhibitor KPT330 inhibited the proliferation of HCC in vitro and in vivo. It caused cell cycle arrest through inducing the accumulation of reactive oxygen species (ROS). Mechanistically, the accumulation of nuclear receptor corepressor (NCOR1) in the nucleus by XPO1 inhibition, potentially leading to abnormal gene transcription that regulates the oxidative state. Through resistance screen, KEAP1 was identified as a key gene whose knockout induced the resistance of HCC cells to KPT330. Deletion of KEAP1 alleviated oxidative stress by activating the NRF2-mediated antioxidant pathway. The combination of XPO1 inhibitor and aldehyde dehydrogenase (ALDH) inhibitor, Disulfiram, synergistically suppressed the HCC development. **Conclusions:** Our study illustrates the potential of XPO1 inhibitor and a drug combination strategy for the treatment of HCC. Furthermore, our data shed light on the mechanism that the response of HCC cells to XPO1 inhibitor is intricately tied to the redox balance.
tumors. Mechanistically, LG markedly down-regulated the expressions of genes associated with pro-inflammatory cytokines, endoplasmic reticulum stress, p62-NeR2 pathway, and cell division in non-tumorous hepatic tissue.

In conclusion, LG attenuates NASH and HCC in diabetic mice. This study may propose a novel solution for serious liver complications of diabetes.

Integrated multiomic analysis in HCC beyond the Milan criteria undergoing liver transplantation

Sunbin Ling1, Qifan Zhan1, Xiao Xu1
1Zhejiang University Hangzhou China

Objective: In patients with hepatocellular carcinoma (HCC) meeting the Milan criteria, liver transplantation (LT) is an extremely effective therapy. We aimed to explore the survival-related molecular biological features in patients with hepatitis B virus (HBV)-related HCC beyond the Milan criteria received LT and to identify the key molecular biology governing the prognosis.

Design: Among 699 consecutive HCC patients undergoing transplant between 2015 and 2019, 122 had tumors exceeding the Milan criteria on pathology and were enrolled in the study. Integrated analyses of tumor tissues were conducted using RNA sequencing (RNA-seq), transposase-accessible chromatin sequencing (ATAC-seq) and proteomic landscape profiling.

Results: At a median follow-up of 34.6 months, 45 patients had died, and 52 had experienced recurrence; the 5-year overall survival (OS) and recurrence rates were 45.0% and 52.0%, respectively. Unsupervised clustering based on transcriptomics identified three subgroups, namely, the low-risk group, medium-risk group and high-risk group. The transcriptomic subgroups significantly differed in OS (high-risk vs. low-risk, hazard ratio (HR) = 4.527). Deep bioinformatics analysis revealed that cancer-associated fibroblast (CAF)-induced cancer stemness may govern the adverse biological features of HCC in the high-risk group. The ATAC-seq identified key transcription factors bridging CAF and stemness profile. Proteomics further validated the transcriptomic subgroup model. Finally, we constructed a three stemness-related protein-based prognostic model to support the transcriptomic subgroup model.

Conclusion: Our observations provided the first multiomic landscape of patients with HCC beyond the Milan criteria undergoing LT. A CAF-stemness-governed classification was constructed to predict the outcomes of patients with HCC beyond the Milan criteria.

The effect of SRC1 inhibitors in hepatitis B-related liver cancer

Agustiningsih Agustiningsih1, Korri Elvanita El Khobar1, Loraine Kay Cabrал1,2, Claudio Tiribelli1,2, Caecilia Sukowati3
1Eijkman Research Center for Molecular Biology, National Research and Innovation Agency of Indonesia Bogor Indonesia, 2Doctoral School in Molecular Biomedicine, University of Trieste Trieste Italy, 3Fondazione Italiana Fegato - ONLUS Trieste Italy

Background and Aims: Hepatitis B virus (HBV) infection is the leading cause of chronic hepatitis B, cirrhosis, and hepatocellular carcinoma (HCC). HBV x protein (HBx) interacts with and modulates a variety of signal transduction pathways leading to HCC, including Src family kinases (SFKs). This study aims to investigate the effect Src inhibitor on HBV infection in an in vitro model of HBV-related HCC.

Method: Hep3B, a HCC cell line with integrated HBV genome was treated with two SRC1 inhibitors, saracatinib (SAR) and dasatinib (DAS) with concentration ranging from 0.02 to 10.00 µM for 24, 48, and 72 hours. Lethal concentrations 50 (LC50) of all treatments were calculated from cytotoxicity assay using MTI test. mRNA and protein expressions SFKs, including SRC/ASF1, FGR, YES, and FYN were assessed by qRT-PCR and Western blot, respectively.

Results: Cytotoxicity test showed dose-dependent toxicity of SAR with LC50 of 2.0 and 3.1 µM for 48 and 72 hours treatment, respectively. SAR and DAS treatments using concentration of 1.25, 2.5, and 5 µM significantly down-regulated the expressions of SRC1 and FGR (p<0.05), while FYN was reduced only by DAS, and YES by SAR. The down-regulation of SRC mRNA was also confirmed by the decrease of protein expression. Interestingly, positive correlations between HBV X gene and SRC1, FGR, and YES were noticed, showing direct association between HBV infection and SFKs.

Conclusion: The inhibition of the SFKs is associated with HBV infection, showing a potential linear correlation between host and pathogen.

Identification of developmental heterogeneity and potential therapeutic targets in HCC

Ming Liu1, Xiao-Feng Zhang1,2, Yun Zhu1, Xiao-Yu Zuo1, Yan Zhang2

1Guangzhou Medical University Guangzhou China, 2Guangzhou Women and Children Medical Center Guangzhou China

Intratumor heterogeneity remains a major obstacle in clinical cancer treatment with limited therapeutic options. In contrast to genetic heterogeneity, the concept of cellular developmental hierarchies and cell-state plasticity driven by non-genetic mechanisms has recently come into sharp focus. With the advancement of single-cell sequencing technology, the clonal evolution and dynamics of cell populations during cancer progression could be monitored at high resolution. To gain insights into HCC tumor heterogeneity, a hepatocyte differentiation model was established to mimic liver development in vitro and utilized to guide the clustering of tumor cells at single cell level from a HCC cohort containing 160 patients. A total of 5 clusters liver parenchymal cells annotated by lineage-specific signature genes were identified. Pseudotime analysis revealed that tumor subpopulations forms a developmental trajectory resembling normal hepatocyte differentiation. RNA velocity analysis indicated that cells at the “root” of developmental trajectory are highly plastic, and constitute the hierarchical heterogeneity with their progenies, which significantly contributed to the poor prognosis in HCC. Multi-color immunofluorescent staining of representative biomarkers further confirmed the existence of developmental heterogeneity in HCC patents. The establishment of hepatocyte differentiation model and algorithms for predicting driver events of the regulatory networks delivers potential therapeutic targets and preclinical candidate compounds, which show high therapeutic potency in patient-derived organoids and xenografts.

Prognosis prediction based on B cell markers through single-cell and bulk RNA-seq analysis for HCC

Yao Yang1, Hongsong Chen1

1Peking University People’s Hospital Beijing China

Tumor-infiltrating immune cells greatly participate in regulating tumorigenesis and metastasis of hepatocellular carcinoma (HCC). B cell, as an important role of specific immunity, plays an indispensable role in antitumor immunity and regulate tumor development. In this study, we firstly identified 345 B cell marker genes of HCC based on single-cell RNA sequencing data. Subsequently, a B cell marker genes-related prognostic signature (BCPS) was developed in the cancer genome atlas (TCGA) cohort for risk stratification and prognosis prediction. The predictive value of the BCPS in prognosis was well validated in different clinical subgroups and two external datasets (IGCG-LIHC cohort, GSE14520 cohort). Moreover, multivariate analysis revealed the independent prognostic value of BCPS for OS in HCC. Further functional analysis indicated the BCPS was associated with basic cellular processes, that may contribute to the development and progression of HCC. Thereafter, immune characteristics as well as the therapeutic benefits in BCPS risk score-defined subgroups were analyzed. Patients with low-risk score exhibited immune-active status, manifested as higher immune scores, more infiltration of CD8+ T cells, and higher T-cell receptor (TCR) richness and diversity. Remarkably, the BCPS was negatively correlated with immunotherapy response-related signatures. In addition, the low-risk group exhibited significantly improved therapeutic benefits, either from immunotherapy or traditional chemotherapy and target therapy. Overall, the BCPS showed an excellent predictive value for prognosis and therapeutic responses for HCC, which might also provide novel insights into better HCC management strategies.

The Urea Cycle Enzyme CPS1 Inhibits the Metastasis of HCC through Recruiting CD8+ T cells

Sisi Zhang1,2, Wenxin Qin3, Jun Xue1, Jing Tang1

1Cancer Center, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China Wuhan China, 2State Key Laboratory of Systems Medicine for Cancer, Shanghai Cancer Institute, Renji Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China Shanghai China

Background: Carbamoyl phosphate synthetase 1 (CPS1) is a metabolic enzyme involved in the production of urea. Our previous studies demonstrated the role of CPS1 in tumor growth and radioresistance in hepatocellular carcinoma (HCC). However, whether CPS1 regulates metastasis and immune evasion remains unclear.

Methods: Transwell and scratch assay were used to detect the function in vitro. Cytometry by time-of-flight was used to screen the differential immune cell groups in the metastasis model. Flow cytometry was utilized to detect the key immune cell subtypes in CPS1-associated tumor immune microenvironment.

Results: The expression of CPS1 was gradually downregulated in normal liver tissue, HCC and metastatic HCC. Overexpression of CPS1 could inhibit the invasion and migration of HCC in vivo and in vitro, respectively. Furthermore, a high level of CPS1 enhanced the infiltration of CD8+ T cells and the production of IFN-γ, granzyme B and perforin, thus impeding the development of HCC. However, the inhibition effect mediated by CPS1 was offset after clearing the CD8+ T cells in C57BL/6 mice. Mechanistically, the inactivation of CPS1 promoted MMP7 upregulation mediated epithelial-mesenchymal transition by activating AKT1/β-catenin signal pathway. CPS1 could induce CD8+ T cells to the tumor site to exert anti-tumor immune effect via stimulating the production of C-X-C motif chemokine ligand 13 (CXCL13). Finally, high CPS1 subtype HCC could further potentiate the responsiveness to immune checkpoint blockade.

Conclusion: These findings indicate that urea cycle key metabolic enzyme CPS1 can hinder the development of HCC and remodel the immunosuppressive tumor microenvironment, thereby enhancing the efficacy of PD-1 checkpoint.

Image analysis highlights distinct fibrosis patterns in combined hepatocellular-cholangiocarcinoma

Hung-Wen Tsai1, Matthew Yeh2, Yayan Ren3, Elaine Chng3, Dean Tai4, Che-Wei Hsu1, Cheng-Yi Chen5, Yoh Zen6

1Department of Pathology, National Cheng Kung University Hospital, College of Medicine, National Cheng Kung University Tainan Taiwan, 2University of Washington, Department of Laboratory Medicine and Pathology Seattle USA, 3Histoindex Pte Ltd Singapore Singapore, 4Department of Cell Biology and Anatomy, College of Medicine, National Cheng Kung University Tainan Taiwan, 5Institute of Liver Studies, King’s College Hospital London United Kingdom
Background: Combined hepatocellular-cholangiocarcinoma (cHCC-CCA) is a distinct entity of primary liver cancer defined by the presence of both hepatocellular carcinoma (c-HCC) and cholangiocarcinoma differentiation (c-CCA) and usually have stem cell-containing transitional zone (TZ) between the two components. Tumor fibrosis stroma more abundant in pure cholangiocarcinoma (p-CCA) than pure HCC (p-HCC) and has been reported to be associated with tumor stemness, invasion and treatment effect. This study is to clarify the fibrosis characters of tumor stroma and its clinicopathologic significance using second harmonic generation/two-photon excitation fluorescence (SHG/TPEF) microscopy.

Methods: We use SHG/TPEF to analyze the collagen structures in 16 cHCC-CCAs, 15 p-HCCs and 15 p-CCAs. Total 16 fibrosis parameters, such as distributed and aggregated collagen for tumor and 184 parameters in the non-tumor were quantified using digital image analysis. Wilcoxon rank sum test was used in the analysis.

Results: c-HCC and c-CCA in cHCC-CCA had more distributed collagen than the p-HCC and p-CCA (P=0.042 and P=0.031, respectively), while there was no difference for the overall fibrosis area or aggregate collagen. TZ contained more distributed collagen than c-HCC (P=0.039), p-HCC (P=0.001) and p-CCA (P=0.028). For non-tumor liver, the liver of the p-CCA patients had lower degree of fibrosis than the cHCC-CCA patients for the parameters in portal tract and peri-portal regions (p<0.05) while there was no significant difference of liver fibrosis between p-HCC and cHCC-CCA cases.

Conclusions: In conclusion, distributed collagen could be a distinct fibrotic pattern in cHCC-CCA. Distributed collagen may be associated with stem cell niche and tumorigenesis of cHCC-CCA.

Abstract Submission No. 100864

HCC-Derived GM-CSF Induces Leukotriene Production in CD163+ TAMs Contributing to Cancer Progression

Takuto Nosaka1, Masahiro Ohtani1, Yu Akazawa1, Kazuto Takahashi1, Tatsushi Naito1, Hidetaka Matsuda1, Yasunari Nakamoto1
1University of Fukui, Faculty of Medical Sciences, Second Department of Internal Medicine Fukui Japan

Background: Tumor-associated macrophages (TAMs) promote cancer progression through cell proliferation and immunosuppression. We observed that macrophages secreted leukotrienes (LTs) in the lung metastasis of hepatocellular carcinoma (HCC) and promoted metastasis. In this study, we investigated the interactions between HCC cells and TAMs and evaluated the potential for targeted therapy.

Methods: We evaluated the number of 5-LOX-positive cells in resected HCC tissue and multivariate analysis associated with overall survival (OS) in 86 patients. Mouse HCC cell line BNL was inoculated intraportally into BALB/c mice, 5-LOX inhibitor was administered, and GM-CSF-transfected BNL cells were injected. Co-culture was performed with mouse bone marrow cell-derived macrophages (BMDM) and HCC cells.

Results: In resected HCC tissues and TCGA-LIHC, the group of patients with high 5-LOX expression had poorer OS (p<0.05). On multivariate analysis, 5-LOX positive cell count was associated with post-operative survival. In the tumor, CD163 (+) TAMs expressed 5-LOX. In HCC mouse model, tumor growth was suppressed by 5-LOX inhibitor. In tumor tissues, GM-CSF expressing cells were tumor cells and increased 5-LOX, CD163, and PD-L1 expression in BMDMs. Moreover, overexpression of GM-CSF in tumor cells promoted the tumor progression. In the co-culture experiment, tumor cells derived GM-CSF increased 5-LOX and CD163 expression in BMDMs.

Conclusions: This study demonstrated a series of mechanisms by which HCC cell-derived GM-CSF promotes 5-LOX and CD163 expression and LT production in TAMs, promoting tumor proliferative potential. Furthermore, the suppression of LT production via GM-CSF from HCC cells regulates tumor progression, suggesting the possibility of a novel therapeutic target.

Inhibition of SFK and its effect on cancer stem cell markers expression in HBV-related HCC

Korri El Khobar1,2, Agustiningsih Agustiningsih1,2, Loraine Kay D. Cabral3, Gianluigi Gianelli1, Claudio Tiribelli2, Caecilia Sukowati1,2
1Eijkman Research Centre for Molecular Biology, National Research and Innovation Agency Cibinong Indonesia, 2Fondazione Italiana Fegato ONLUS Trieste Italy, 3National Institute of Gastroenterology "S. De Bellis" Research Hospital Bari Italy

Background: Chronic infection of hepatitis B virus (HBV) remains the main etiological factor for hepatocellular carcinoma (HCC). HBV-related HCC pathogenesis has been associated with the expression of HBV X protein (HBx), which can interact directly with key regulatory protein including Src family kinase (SFK). HBx interaction with Src are important for regulation of stem-like properties and liver cancer formation. Here, we determined the effect of treatment with Src inhibitors on cancer stem cell (CSC) markers expression in HBV-related HCC.

Methods: Hep3B, a HCC cell line with integrated HBV genome, was treated with two Src inhibitors, saracatinib (SAR) and dasatinib (DAS) with increasing doses of 1.25, 2.5, and 5.0 µM for 48 hours based on each of their LC50 concentrations. mRNA and protein expressions of different CSC markers and other liver-related markers were assessed by qRT-PCR and flow cytometry.

Results: Hep3B cells highly expressed CSC markers EpCAM, CD13, CD133, and CD24, but only lowly expressed PD-L1, CD95 and its ligand CD95L. Treatment with SFKs inhibitors, SAR and DAS, reduced both Src gene and protein expressions. SAR treatment increased CD133 (p<0.01) but reduced CD90 expressions, while DAS treatment caused no changes in other CSC markers. In addition, SFK inhibitors also reduced fibrosis markers, TGFβ1, ACTA2, HGF, CTGF, and FSP1, and have no significant effects on liver marker AFP and albumin expressions, mostly noted for SAR.

Conclusion: Src inhibitors treatment may have anticancer effect by reducing the expression of CSC markers, as well as a possible antiangiogenic effect in HBV-related HCC.

PSMP suppresses HCC progression through inhibiting macrophage M2 polarization via PI3K/Akt pathway

Shaoping She1, Yao Yang1, Liying Ren1, Dongbo Chen1, Hongsong Chen1
1Peking University People’s Hospital, Peking University Hepatology Institute, Beijing Key Laboratory of Hepatitis C and Immunotherapy for Liver Diseases Beijing China

Hepatocellular carcinoma (HCC) is the most common primary malignancy of the liver and represents a major global health-care challenge.
PC3 secreted microprotein (PSMP) is a novel chemotactic cytokine that can recruit peripheral blood monocytes and lymphocytes through CCR2. Our previous study found that PSMP promotes the progression of liver fibrosis by regulating the infiltration, activation and polarization of macrophages. However, the relationship between PSMP and the development of HCC remains unclear.

Through clinical samples, we found that PSMP is downregulated in human HCC tissues, and its expression level is positively correlated with the prognosis of HCC patients. In vivo, we found that genetic deletion of PSMP promotes subcutaneous and liver orthotopic tumor growth and metastasis in mice; Overexpression of PSMP inhibits the formation of subcutaneous tumors in nude mice. Mechanistically, deletion of PSMP substantially suppresses the infiltration of CD8⁺ lymphocytes while promoting the infiltration and polarization of M2 tumor-associated macrophages (TAMs) within the liver. In vitro, we observed that PSMP possesses the capacity to induce M1-polarization and suppress M2-polarization of macrophages. In addition, analysis of RNA sequencing results showed that PSMP may mediate the polarization of macrophages by regulating the PI3K/Akt pathway. Then, we verified that PSMP mediates its inhibitory effect on M2-polarization of macrophages through inhibition of p85 and Akt phosphorylation.

Collectively, PSMP may inhibit macrophage M2 polarization by downregulating PI3K/Akt signaling. The results are expected to clarify the role and mechanism of PSMP in the liver tumor microenvironment for the first time, which has important theoretical significance and potential application value.

Investigation on the Tumor suppressor role of miR-3185 in Hepatocellular Carcinoma

Inah Marie C. Aquino¹, Leslie Michelle M. Dalmacio¹, Claudio Tiribelli², Devis Pascut²

¹University of the Philippines Manila, College of Medicine Manila Philippines, ²Fondazione Italiana Fegato - ONLUS Trieste Italy,

Background: Hepatocellular carcinoma (HCC) is a leading cause of cancer-related deaths worldwide. Serum miR-3185 has emerged as a potential biomarker in HCC, with higher levels associated with better prognosis. However, the role of miR-3185 in the disease remains unclear. This study aimed to elucidate the function of miR-3185 in liver cancer.

Methods: The MiR-3185 target genes were predicted by using TargetScanHuman 7.2 and miRDB. HCC-derived JHH6 cells were transfected with miR-3185 mimic and scramble control. mRNA and protein expression of target genes were assessed at 24h, 48h, and 72h post-transfection. Putative targets were validated by using a 3'UTR miR-target gene reporter system. Cell viability, cell cycle and migration were evaluated to describe the roles of miR-3185 in the in vitro model.

Results: In silico analysis identified eight miR-3185 target candidates. Among those, SLC39A11 was identified as the main miR-3185 target. miR-3185 mimic significantly reduced SLC39A11 mRNA at 24h, 48h, and 72h and its protein expression at 48h and 72h. The 3'UTR miR-target gene reporter assay confirmed the targeting of SLC39A11, resulting in a 58% reduction in luciferase activity. The inhibition of SLC39A11 expression resulted in significant decreased cell viability, increased G0/G1 phase cell cycle arrest and repressed cell migration.

Conclusion: SLC39A11 is a miR-3185 target in HCC. The inhibition of this essential zinc transporter reduced cell viability and migration, thus supporting the role of miR-3185 as a tumor suppressor.

Disparity landscapes of HBV integration in liver cancer: mechanistic and functional implications

Daniel Wai-Hung Ho¹, Xueying Lyu¹, Karen Man-Fong Sze¹, Joyce Man-Fong Lee², Abdullah Husain¹, Irene Oi-Lin Ng¹

¹Department of Pathology and State Key Laboratory of Liver Research, University of Hong Kong Hong Kong China

Background: Hepatocellular carcinoma (HCC) is a leading fatal malignancy worldwide and chronic hepatitis B virus (HBV) infection accounts for ~50% of the cases. HBV DNA integrates into the human genome, disrupting the endogenous tumor suppressors/regulatory genes, or enhancing the activity of proto-oncogenes.

Methods: We determined the disparity landscapes of integration events among sample cohorts, tissue types, chromosomal positions, individual host/viral genes, as well as genic locations. Moreover, we performed mechanistic investigation on how HBV-TERT integration led to TERT activation and derived a score to predict patients’ prognosis according to their clonal disparity landscape of HBV integration.

Results: We revealed the global geographical disparity of HBV integration that the landscape of HBV integration between HCC and non-
tumorous liver varied in regional cohorts, suggesting different degrees of clonal enrichment. Most HBV integrations were positionally enriched at telomeres and centromeres, and they highlighted the novel co-involvement of HBV integration, which likely introduces genomic instability. We constructed a large meta-cohort of multiple ethnicities to refine the landscape of HBV integration. This enables the geneset/gene-family-level exploration. As TERT is the most frequently integrated gene, we further investigated the mechanistic modulation of TERT transcription activation and revealed the concurrent influence by the orientation and relative distance of HBV integration. Additionally, clonal disparity of HBV integration was observed among patients and the higher level of clonal disparity score indicates poor patients' prognosis.

Conclusions: Our study uncovered the different levels of clonal enrichment of HBV integration, mechanistic insights, and prognostic biomarker, to strengthen our understanding in HBV-associated hepatocarcinogenesis.

Unique pattern of cell-cell interaction in Cytoglobin knock-out mice promoting liver tumor formation

HA THI NGUYEN1, THUY THI THANH LE1, HAI HOANG1, DUC MINH PHAM1, NORIFUMI KAWADA1

1Osaka Metropolitan University, Graduate School of Medicine, Department of Hepatology Osaka Japan, 2Osaka Metropolitan University, Graduate School of Medicine, Department of Global Education and Medical Sciences Osaka Japan

Background: Cytoglobin (Cygb), the newest member of the mammalian globin family, has shown protective function in anti-fibrotic properties. This study investigated the cell-cell interaction in the liver tumor and non-tumor area of wild-type (WT), CYGB deficient (Cygb-KO), and Cygb overexpression (Cygb-TG) using both whole tissue transcriptomic (RNAseq) and single-cell RNA sequencing (scRNA-seq) analysis.

Method: Mice were administrated with Diethyl nitrosamine (DEN) by percutaneous injection at 6 µg/g BW at 15-day-olds and observed for 12 months. RNA from liver tissues was used for RNAseq. Primary non-parenchyma cells isolated from DEN-treated livers were performed scRNA-seq by 10X Genomics.

Result: The mean number of liver tumors in WT was 4.76 compared to 1.51 in Cygb-TG, p < 0.001; and the maximum size of liver tumors was 7.4 mm in WT compared to 2.05 in Cygb-TG mice, p < 0.01. Heatmap analysis of whole liver transcriptomic data revealed the suppression of DNA-damage inducible genes and stimulation of antioxidant-related genes in TG livers. The integrated scRNA-seq data and annotation identified 10 cell types including 2 subtypes of macrophage and 2 subtypes of HSC. Liver sinusoid endothelial cell (LSEC) is the most abundant population. nicheNet analysis demonstrated a unique pattern in the KO niche which highlighted robust interactions of receptors in LSEC with the ligands from other non-parenchymal and immune cells in comparison with those of WT. These ligands are neuron growth factors from HSCs, transferrin from cholangiocytes and NKs, and galectin 3 from tumor-associated macrophages. The validation cohort of 364 patients with HCC demonstrated these factors are correlated with overall survival.

Conclusion: Both RNAseq and scRNAseq revealed the transcriptomic profile changing in various cell types between KO and WT mice, while the interaction with other non-parenchymal cells and immune cells from KO liver may drive functional characteristics in LSEC and promote tumor development.

Novel disease-associated hepatocyte state can predict the future risk of liver cancer development

Janina Tiritz-Parker1,2, Rodrigo Carlessi1,2

1Curtin University Bentley - Perth Australia, 2Harry Perkins Institute of Medical Research Perth Australia

Rationale: Hepatocellular carcinoma (HCC) constitutes approximately 80-90% of primary liver cancers and is frequently identified at an advanced stage, where treatment choices are limited, while prognosis and survival are poor. Conversely, early detection of HCC substantially improves outcomes, rendering it potentially curable. Presently, it is challenging to pinpoint which patients will develop HCC, as current methods for staging chronic liver disease (CLD) are ineffective for predicting HCC.

Our study: In our research, we utilised single-nucleus RNA sequencing (snRNA-seq) to delineate the cellular microenvironments in both healthy and pre-malignant livers via established mouse models (CDE, TAA, MUP-uPA). Subsequent analysis revealed a disease-associated hepatocyte (daHep) transcriptional state not found in healthy livers but increasing in prevalence with advancing CLD. Copy number variation (CNV) analysis of micro-dissected tissues indicated that regions enriched with daHeps harboured extensive structural variants, implying that these cells may be an intermediary to malignancy. Examination of three contemporary human snRNA-seq datasets corroborated the existence of similar cellular phenotypes in human CLD and indicated a higher mutational load. Crucially, elevated daHep levels were shown to predict oncogenesis, suggesting a greater risk of developing HCC.

Ongoing research: We are now employing Oxford Nanopore long-read sequencing to investigate genome-wide methylation patterns of human pre-malignant daHeps to establish a non-invasive assay using methylated cDNA from blood samples and quantify daHep levels to assess the subsequent risk of HCC. These insights have the potential to revolutionise the staging, monitoring, and risk assessment of patients with CLD.

Traditional Chinese medicine compound and anti-tumor immunity

Rui Hu1,2, Jing Li1,2, Qi Huang1,2, Xin Zheng1,2, Jialing Sun1, Jin Yu1,2, Lanfen Peng1, Xingping Liu1,2, Yuan Yang1, Wenmin Yang3, Yan Wang4, Wenfeng Ma5, Wenxing Feng5, Youhua Xu5, Xiaozhou Zhou1,2,3

1Shenzhen Traditional Chinese Medicine Hospital Shenzhen China, 2Macau University of Science and Technology Macao China, 3The fourth Clinical Medical College of Guangzhou University of Chinese Medicine Shenzhen China

Background: The cell cycle inhibitor p21 triggers targeted immunokilling by p21-activated secretory phenotype (PASP). Qizhu Kangai formula (QZKAF) has anticancer functions but the underlying mechanisms involving PASP remain unclear.

Purpose: This study aimed to investigate the mechanisms of QZKAF in inhibiting the progression of hepatocellular carcinoma (HCC) related to PASP.
HCC development and associated with the infiltration of natural killer cell chemokine ligand 14, and Wnt family member 2 were involved in reversing the immunosuppressive microenvironment. This study could provide new insights into the anticancer effect of QZKAF. The pathological features of liver were observed using hematoxylin and eosin (H&E) staining. The screening of PASP was performed by GeneCards, DisGeNet, Online Mendelian Inheritance in Man, and The Cancer Genome Atlas databases. Western blotting, immunofluorescence, and transwell assays were also used.

**Results:** QZKAF-containing serum enhanced p21 expression, accelerated cell senescence, triggered cell cycle arrest, and inhibited cell proliferation in Huh7 and MHCC-97H cells. QZKAF decreased the number and size of liver tumor nodules and enhanced p21 expression. SA-β-Gal staining of tumor lesions, and cytotoxic CD8+ T cell infiltration. Decorin, dermatopontin, hepatocyte growth factor, C-X-C motif chemokine ligand 14, and Wnt family member 2 were involved in HCC development and associated with the infiltration of natural killer cells and CD8+ T cells in the tumors.

**Conclusion:** QZKAF suppression of HCC progression may involve P21 up-regulation-mediated cell senescence, the secretion PASP, and reversing the immunosuppressive microenvironment. This study could help new strategies for improving HCC treatment.

**Combinational therapeutic targeting of BRD4 and CDK7 induces anticancer effects in HCC**

**Xinxiu Li¹, Hong Fan¹**

¹Medical School, Southeast University, Nanjing, China. Nanjing China

**Objectives:** In hepatocellular carcinoma (HCC), oncogenes are continuously and robustly transcribed due to aberrant expression of essential components of the trans-acting super-enhancers (SE) complex. Preclinical are now being conducted on small-molecule inhibitors that target core-transcriptional components, including as transcriptional bromodomain protein 4 (BRD4) and cyclin-dependent kinase 7 (CDK7), in many malignant tumors. We aim to explore whether co-overexpression of BRD4 and CDK7 is a potential marker of worse prognosis and a combined therapeutic target in HCC.

**Methods:** The expression pattern of BRD4 and CDK7 and their correlation with prognosis in HCC from TCGA and GEO datasets were analyzed. The protein levels of BRD4 and CDK7 were determined by immunohistochemistry, and survival data of patients were analyzed using the Kaplan-Meier method. The mRNA expression levels of genes in HCC cells were evaluated by q-PCR. CCK-8 and colony formation assays were conducted to assess cell proliferation of HCC upon treatment with BRD4 inhibitor JQ1 or/and CDK7 inhibitor THZ1.

**Results:** Co-overexpression of CDK7 and BRD4 was a worse prognostic factor in HCC. Treatment with JQ1 or THZ1 alone had an inhibitory effect on cell proliferation; however, when JQ1 and THZ1 were combined, there was a more notable suppression of cell growth. At the same time, the combined use of JQ1 and THZ1 synergistically suppresses the expression of HCC driver genes.

**Conclusion:** Our research revealed that BRD4 and CDK7 coupled can be a useful biomarker in HCC prognosis and the combination of JQ1 and THZ1 can be a promising therapeutic therapy against HCC.

**Development of the Liver Tumor-bearing Rat Model with Dual Optical Imaging**

**Naoki Yokota¹, Haruyuki Takaki¹, Yutaka Hirata², Reona Wada¹, Taishi Kodama¹, Kouichiro Yamakado¹**

¹Department of Radiology, Hyogo Medical University Nishinomiya City Japan, Specialty of biodynamics, Department of physiology, Hyogo Medical University Nishinomiya City Japan

**PURPOSE:** This study aims to develop the liver tumor-bearing rat model that stably co-expresses both luciferase and a red fluorescent, and is quantitatively and qualitatively monitorable by the optical imaging system.

**Methods:** The plasmids encoding both luciferase and red fluorescence proteins were transfected to the NIS1 rat hepatoma cell lines. Those cell lines were inoculated to the liver of the Spraque-Dawley rats (n=6). All animals underwent both in vivo bioluminescence and fluorescence imaging one week after tumor inoculation. Then, animals were assigned to receive hepatic artery embolization (HAE) (HAE group, n=3) or sham treatment (sham group, n=3). All animals underwent optical imaging again 24 hours after the procedure and liver tissues were harvested. Changes in the intensity of optical imaging were evaluated. The harvested liver tissues were observed by fluorescence microscopy.

**Results:** Liver tumors were identified by bioluminescence imaging in all 6 animals at 1 week after tumor inoculation (100%, 6/6). The signal intensity of bioluminescence significantly decreased after HAE (P<0.05), whereas it remained unchanged in the sham group (P=0.12). The tumor necrosis areas were more than 90% in the HAE group and less than 30% in the sham group, respectively. The tumor area of the unstained liver tissue could be identified in all animals (100%, 6/6) on fluorescence microscopy imaging.

**Conclusion:** Tumor-bearing rat model that stably co-expresses both luciferase and a red fluorescent was successfully developed. This model will be useful in the translational research of interventional oncology.

**Rab14 potentiates CD147 cytoplasm translocation to promote HCC metastasis by NME1-mediated pathway**

**Meng Lu¹,², Zhiyun Zhang¹,², Peng Lin¹,², Haolin Wei¹,², Zhiwei Yang³, Xinhuai Cai³, Zekun Liu³, Lin He¹,², Lei Zhang³, Zhinan Chen³, Huijie Bian³**

¹Department of Cell Biology, National Translational Science Center for Molecular Medicine, Fourth Military Medical University Xi’an China, ²State Key Laboratory of New Targets Discovery and Drug Development for Major Diseases Xi’an China, ³MOE Key Laboratory for Nonequilibrium Synthesis and Modulation of Condensed Matter Xi’an China

The correct subcellular localization of proteins is essential for their physiological functions, cell homeostasis and signal network transmission. CD147, localized in the basolateral membrane of hepatocytes, functions as signal transduction molecule to regulate complicated pathway between extracellular to intracellular signals, to improve hepatocellular carcinoma (HCC) progress. However, few studies focused on the CD147 distribution. Here we found in comparison with HCC cells expressing wild-type CD147 (CD147WT), mutated CD147 (CD147L249A) showed cytoplasmic enrichment, enhancing HCC cells more aggressive phenotype characteristics with epithelial to mesenchymal transition (EMT) and invasion. Cytoplasm-anchored CD147
CRISPR screen for kinase potentiating T cell-mediated cytotoxicity in hepatocellular carcinoma

Ka Hei Lam1, Kai Yu Ng1, Tin Lok Wong1, Ianto Bosheng Huang1, Guang Sheng Ling1, Stephanie Kwai Yee Ma1, 2
1School of Biomedical Sciences, Li Ka Shing Faculty of Medicine, The University of Hong Kong Hong Kong, 2State Key Laboratory of Liver Research, The University of Hong Kong Hong Kong

Background: Despite achieving durable clinical responses in multiple malignancies, the overall response rate to immune checkpoint blockade (ICB) for hepatocellular carcinoma (HCC) patients remains relatively low. This necessitates immediate efforts to identify the factors responsible for the resistance to immunotherapy and devise novel strategies that can augment antitumor activity of ICB through synergistic approaches. Cytotoxic T lymphocytes (CTLs) are the central effectors of anti-tumor immune response. Understanding the relationship between tumor intrinsic kinases and CTL-mediated cytotoxicity could reveal novel mechanisms in promoting responses to immunotherapy.

Methods: Cas9-expressing mouse HCC cells were overexpressed with ovalbumin (OVA), then transduced with kinome knockout library. Cells were co-cultured with activated OVA-specific OT-1 CD8+ T cells followed by next-generation sequencing of gRNA representation. MaGeCK analysis was used to define the top genes that affected tumor cell killing by cytotoxic T cells.

Results: Top hits from the screen were validated in vitro and loss of target gene was shown to reduce tumor burden in an immune-dependent manner. Mechanisms by which the target genes regulate T cell killing and modifications in tumor microenvironment are currently under investigation.

Conclusion: By identifying key genes involved in T cell-mediated cytotoxicity and validating their impact on tumor burden, the research emphasizes the importance of understanding the interplay between tumor intrinsic kinases and immune responses. These findings provide insights that can guide the development of novel therapeutic strategies to enhance the effectiveness of immunotherapy in HCC.

A Precision Therapy Targeting Replication Stress in Hepatocellular Carcinoma by WEE1 Inhibition.

Xing Jia1

Division of Hepatobiliary and Pancreatic Surgery, Department of Surgery, The First Affiliated Hospital, Zhejiang University School of Medicine Hangzhou China

Background: The diversity of hepatocellular carcinoma (HCC) necessitates more individualized and effective treatment strategies for advanced cases.

Methods: We sequenced 178 proteomic and 94 transcriptomic clinical samples for HCC subtype identification. Employing Kinome CRISPR screening and patient-derived xenograft drug assays, we explored synergistic therapeutic combinations for different HCC subtypes. We verified the synergistic effect of oxaliplatin and adavosertib through in vitro and in vivo models. To elucidate the synergistic mechanism of oxaliplatin and adavosertib in HCC cells, we utilized whole transcriptomic sequencing, confocal imaging, Western Blot, and pDR-GFP or pimeJ5-GFP reporter systems for the detailed investigation.

Results: Both proteomic and transcriptomic subtyping analyses revealed that subtypes with hyperproliferative features have the worst prognosis and highest replication stress (RS) levels. Oxaliplatin, among the clinical first-line agents, heightened RS in HCC, with WEE1 as a synergistic point of action. We demonstrated the synergy between the WEE1 inhibitor adavosertib and oxaliplatin. Mechanistically, adavosertib inhibits oxaliplatin-induced homologous recombination repair and G2/M checkpoint activation, leading to fatal DNA damage and forcing cells with DNA damage into mitosis. High RS levels in HCC patients were associated with poorer prognosis but predicted a better response to the adavosertib-oxaliplatin combination, as confirmed by preclinical models through unsupervised clustering analysis.

Conclusions: Our study proposes a novel classification and treatment strategy for HCC based on tumor RS levels, potentially enriching precision medicine with direct clinical implications.

Abstract Submission No. 101710

miR-485-3p as a predictive biomarker in Atezo/Beva therapy and analysis of PIAS3/STAT3/VEGF signal

Kyoko Oura1, Asahiro Morishita1, Kei Takuma1, Mai Nakahara1, Tomoko Tadokoro1, Koji Fujita1, Joji Tani1, Tsutomu Masaki1
1Department of Gastroenterology and Neurology, Faculty of Medicine, Kagawa University, Kagawa Takamatsu Japan

Objective: Atezo/Beva therapy has been shown to be effective for uHCC, and miRNA targeting VEGF is associated with therapeutic effect. In this study, we focused on the usefulness of miR-485-3p as a early predictive marker and analyzed the mechanisms related to PIAS3/STAT3/VEGF.

Methods: Sixty-six patients with uHCC treated with Atezo/Beva from 2020 to 2022 were included. Contrast-enhanced CT at 6 weeks was evaluated by modified RESIST and divided into response group (CR+PR) and non-response group (SD+PD). In vitro, HuH-7 and HUVEC were co-cultured, miR-485-3p was transfected, and cell migration and proliferation ability were analyzed. miRNA expression was analyzed by RT-PCR and protein expression by Western blot.

[Results] Comparing 44 patients in the response group with 22 patients in the non-response group, 10 miRNAs were significantly elevated before treatment in the response group, especially miR-485-3p, which was higher than in the non-response group and further elevated 3 weeks later. Serum VEGF levels before treatment were not significantly different, but both groups decreased to below detection sensitivity the next day, and the 3-week/pre-treatment ratio was significantly lower in the response group than in the non-response group. In multivariate analysis, miR-485-3p elevation at baseline was a significant factor related to therapeutic response. In vitro, miR-485-3p suppressed migration and proliferation in HuH-7, enhanced
PIAS3 expression, and suppressed STAT3/VEGF expression, which were more pronounced in cells co-cultured with HuVEC.

Conclusion: Serum miR-485-3p is useful for predicting early treatment response, and PIAS3/STAT3/VEGF signals are associated and may have clinical applications in biomarker and drug development.

Abstract Submission No. 101721

In vitro therapeutic effects of Bosentan and Obeticholic acid on Hepatocellular Carcinoma Cells

Necati Ormeci1, Sina Kilic2, Gulden Budak1, Ayca Uvez2, Sinasi Bayram1, Ece Zehra Ekinikili1, Elif Ilkay Armutuk2

1Istanbul Health and Technology University, Faculty of Medicine Istanbul Turkey, 2Istanbul University-Cerrahpasa, Faculty of Veterinary Medicine Istanbul Turkey

Background: Hepatocellular carcinoma (HCC) is the second liver tumor with a high mortality rate. High plasma endothelin-1 B (ET-1) level in HCC patients is an important marker of portal hypertension pathogenesis. Expression of Farnesoid X receptor Obeticholic acid (OCA), responsible for hepatoprotective effects are significantly reduced in human HCC tumor tissue.

Method: The in vitro anti-proliferative, cytostatic and cytotoxic efficacy of the Bosentan, OCA and Bosentan+OCA were investigated. EA.hy926 and HepG2 cell lines were treated with Bosentan, OCA and Bosentan+OCA for 48 h at various concentrations (0-200µM). SRB cell viability and colony formation assays were performed in EA.hy926.

Results: GI50, TGI, and LC50 parameters representing the anti-proliferative, cytostatic, and cytotoxic effects were calculated at 48h, respectively. Bosentan and OCA revealed lower cytotoxic effects on HepG2 cells compared to EA.hy926, control cell line, (LC50>200). Bosentan had lower cytostatic and anti-proliferative effect than OCA on HepG2 cells. Bosentan 25 µM and Obeticholic acid 50-25 µM showed a slight reduction in colony number and size compared to control. Bosentan (50-200 µM) alone, OCA (100-200 µM) alone and Bosentan+OCA combination showed a dose-dependent reduction in cell viability and colony formation ability.

Conclusion: In this study, combined use of Bosentan and OCA were found to increase the cytotoxic effect in both cell lines by showing a synergistic effect. Higher doses of Bosentan+OCA causes loss of healthy cells due to resistance in HepG2 cells emphasizes the need for targeted therapies.

Abstract Submission No. 101746

Transcriptome sequencing was used to analyze the mechanism of CENPF involved in regulation of hec

Ying Zhang1, Xue-Fei Wei1, Jie-Ru Yang1, Ji-Hui Li1, Xing Su1, Zhao-Hui Wang1, Peng-Yu Luo1, Nan Chen1, Pei Liu1, Yu-Chen Fan1, Kai Wang1

1Qilu Hospital of Shandong University Jinan China, 2Hepatology Institute of Shandong University Jinan China

Objective: This study is based on analysis of the transcriptome study technology, to explore the mechanism of action of CENPF to participate in the regulation of HCC.

Methods and Results: In this study, the mRNA expression of 20 pairs of HCC tissue and paracancerous tissue samples was examined using transcriptomics technology. By analyzing the differentially expressed genes between HCC and adjacent tissues. Ten target genes were selected for verification by RT-qPCR, and CENPF gene was screened. The expression levels in normal liver cells L02 and liver cancer cell lines HepG2, PLC, Huh7 and Hep3B were detected, and immunohistochemical staining and Western blot were performed on paraffin sections of liver cancer tissues. The results showed that CENPF was significantly increased in HCC tissues compared with normal liver tissues. Western blot was used to verify the expression of signal pathway related proteins in HepG2 and Huh7 cells with CENPF overexpression and knockdown. GO analysis revealed that CENPF was related to 243 biological processes, and CENPF was mainly involved in cytokaskeleton formation, cell mitosis, protein binding and other processes. KEGG analysis showed that CENPF mainly involved in the AKT/mTOR, TNF, JAK - STAT signaling pathways are closely associated with cancer. There were significant differences in PISK and p-AKT between the knockdown group and the overexpression group.

Results: CENPF is mainly involved in regulating the signaling pathway of liver cancer, which provides a new way to elucidate the mechanism of CENPF on HCC.

Abstract Submission No. 101843

MicroRNA-491 ameliorates lenvatinib resistance in hepatocellular carcinoma cells

Takayuki Kogure1, Mari Satoh1,1, Masanori Takahashi2, Takehito Ito1, Kouji Okada2, Kensuke Usui2, Kennichi Satoh1

1Division of Gastroenterology, Tohoku Medical and Pharmaceutical University Sendai Japan, 2Department of Pharmacy, Tohoku Medical and Pharmaceutical University Sendai Japan, 3Department of Internal Medicine, Tohoku Medical and Pharmaceutical University Wakabayashi Hospital Sendai Japan, 4Department of Internal Medicine, Tome City Toosato Hospital Tome Japan

Lenvatinib, a multi-kinase inhibitor, has demonstrated superior response rates in hepatocellular carcinoma (HCC) treatment. However, overall survival remains non-inferior to sorafenib, suggesting the development of resistance during treatment. Lenvatinib induces severe hypoxia in tumors by inhibiting VEGF receptors, potentially playing a critical role in multi-kinase inhibitor resistance. This study aims to elucidate the mechanism of lenvatinib resistance under hypoxia in HCC. Human HCC cell lines PLC/PRF/5, Huh7, Hep3B, and HepG2 were cultured under normoxic or hypoxic conditions. Hypoxia increased HIF1α expression without significantly affecting cell growth until 96 hours. Lenvatinib inhibited cell growth in a concentration-dependent manner, but this cytotoxicity was reduced under hypoxia, indicating resistance acquisition.

MicroRNA profiling revealed that 48 microRNAs were differentially expressed in lenvatinib-treated PLC/PRF/5 cells under normoxia (42 increased, 6 decreased). Of the 42 increased microRNAs, 28 showed decreased expression in lenvatinib-treated PLC/PRF/5 cells under hypoxia. Among these, miR-491 exhibited the most significant change in expression. Forced expression of miR-491 partially restored lenvatinib cytotoxicity under hypoxia. Similar results were observed in all tested cell lines. Genome-wide miRNA profiling identified 168 genes commonly alternated by miR-491 forced expression in PLC/PRF/5, Huh7, and HepG2, associated with RNA splicing, cell cycle, and cell adhesion pathways.

In conclusion, miR-491 contributes to hypoxia-induced lenvatinib resistance in HCC, and modulating its expression partially restores lenvatinib cytotoxicity. These findings highlight the potential of targeting microRNAs to overcome lenvatinib resistance.
UBE2S promotes tumor glycolysis by enhancing K11-linkage ubiquitination at lysine 171 and 196 of VHL

Ren-Yu Zhang1, Huijie Bian1
1Department of Cell Biology, National Translational Science Center for Molecular Medicine, Fourth Military Medical University Xi’an China

Background: Ubiquitination is widely involved in the progression of hepatocellular carcinoma (HCC) by regulating various cellular processes. However, systematic strategies for screening core ubiquitin-related genes, clarifying their functions and mechanisms, and ultimately developing potential therapeutics for patients with HCC are still lacking.

Methods: Cox and LASSO regression analyses were performed to construct a ubiquitin-related gene prediction model. Loss- and gain-of-function studies, transcriptomic and metabolomics analysis were used to explore the function and mechanism of UBE2S on HCC cell glycolysis and growth.

Results: Based on 1423 ubiquitin-related genes, a four-gene signature was successfully constructed to evaluate the prognosis of patients with HCC. UBE2S was identified in this signature with the potential to predict the survival of patients with HCC. E2F2 transcriptionally upregulated UBE2S expression by directly binding to its promoter. UBE2S positively regulated glycolysis in a HIF-1α-dependent manner, thus promoting the proliferation of HCC cells. Mechanistically, UBE2S enhanced K11-linkage polyubiquitination at lysine 171 and 196 of von Hippel-Lindau tumor suppressor (VHL), thereby indirectly stabilizing HIF-1α protein levels. In particular, the combination of cephalmannine, a small molecule compound that inhibits the expression of UBE2S, and PX-478, an inhibitor of HIF-1α, significantly improved the anti-tumor efficacy.

Conclusions: This study identified UBE2S as a key biomarker among the thousands of ubiquitin-related genes and elucidated its mechanism in promoting glycolysis in HCC cells by regulating VHL/HIF-1α signaling pathway, thus providing therapeutic candidates for the treatment of HCC.

Nimbolide reduces tumor growth and metastasis by regulating miR145 expression in liver cancer

Balasubramaniyan Vairappan1, Siva Bala subramanian1, Victor Mukherjee1
1JIPMER Pondicherry India

Background: Liver cancer remains a substantial public health problem and represents the 3rd leading cause of cancer-related deaths globally. However, many advanced therapies are in place, the prognosis remains poor. Here, we aim to ascertain the anti-cancer and metastatic effects of Nimbolide (a major limonoid constituent of Azadirachta indica) by regulating specific microRNA 145 and its target genes in experimental liver cancer.

Methods: Diethyl nitrosamine and N-nitrosomorpholine-induced hepatocellular carcinoma (HCC) mice were administered Nimbolide (6mg/kg b.wt.) orally for four weeks following induction of HCC at 28 weeks.

Results: We found significantly decreased expressions of miR145 in HCC mice compared to naive. Following treatment with Nimbolide to HCC mice showed increased miR145 expression considerably. Moreover, miR145 direct target genes such as MUC1, ROCK-1, MMP-9 and ADAM 17 were significantly elevated in HCC and were downregulated following Nimbolide treatment. The epithelial-mesenchymal transition (EMT) markers E-cadherin expression decreased whilst N-cadherin expression increased in HCC mice. Furthermore, miR145 inhibitor treatment to HepG2 cells showed increased MUC1, ROCK-1, MMP-9, ADAM 17 and EMT marker expression. Nimbolide treatment positively regulated the above indices.

Conclusion: Our novel data suggested that Nimbolide treatment improved miR145 expression and decreased its target genes involved in cancer growth and metastatic development in HCC. Consequently, Nimbolide could be considered a future therapeutic approach in managing HCC pathogenesis.
Abstract Submission No. 101980

Cancer cell produce liver metastasis via intracellular gap formation in sinusoidal endothelial cells

Hoang Truong1, Misako Sato-Matsubara2, Hideto Yuasa2, Tsutomu Matsubara2, Le Thi Thanh Thuy2, Jordi Gracia-Sanchez3, Norifumi Kawada2

1Cancer Institute, Military Central Hospital 108 Hanoi Vietnam, 2Osaka Metropolitan University Osaka Japan, 3IDIBAPS Biomedical Research Institute Barcelona Spain.

Background: Intracellular gap (iGap) formation in liver sinusoid endothelial cells (LSECs) is caused by the destruction of fenestrae under pathological conditions, but the role of LSECs-iGap in liver metastasis is still unclear.

Methods: Mouse models using acetaminophen or thioacetamide followed by intrasplenic injection of hepatocellular carcinoma (HCC) cell line, Hepa1-6 cells, to assess the LSECs-iGap formation. Functional effects of LSECs-iGap on cancer cells were analyzed using MMPs inducer, monocrotaline, and inhibitor, doxycycline. The data was collected using electron microscopic, RNA-sequencing, cytokine array, and endothelial trans-endothelial migration assay in vitro mouse models and in vitro co-culture system. Biopsy specimens from 98 patients with HCC were statistically evaluated using immunohistochemical staining.

Results: Acetaminophen-induced liver injury and thioacetamide-induced fibrotic liver resulted in LSECs-iGap formation, which positively correlated with increased numbers of metastatic foci after Hepa1-6 cells injection. In addition, Hepa1-6 cells induced IL-23-dependent TNF-α secretion by LSECs and triggered LSECs-iGap formation, toward which their processes protruded to transmigrate into the liver parenchyma. TNF-α caused depolymerization of F-actin and increased MMP9, ICAM1, and CXCLs expression in LSECs. Interestingly, high MMP9 activity by doxycycline and MMP-2/9 inhibitor eliminated monocrotaline or Hepa1-6 cells induced LSECs-iGap formation, which was accompanied with attenuated liver metastasis by Hepa1-6 cells.

Conclusion: This study revealed that cancer cells induced LSEC-iGap formation via pro-inflammatory paracrine mechanisms and proposed MMP9 as a novel target for blocking cancer cell metastasis to the liver.

Abstract Submission No. 102049
O-0577

Determinants of hepatocellular carcinoma in alcohol liver disease patients

Priyanka Shenoy1, Manya Prasad2, Shiv Kumar Sarin3

1Institute of Liver and Biliary Sciences New Delhi India, 2Institute of Liver and Biliary Sciences New Delhi India, 3Institute of Liver and Biliary Sciences New Delhi India

Background: This study aims to determine the drinking pattern and patient characteristics that make Alcohol Liver Disease (ALD) patients susceptible to develop Hepatocellular Carcinoma (HCC).

Methods: A Case Control study was conducted in Out Patient Department of tertiary care liver hospital from November 2022 to August 2023. ALD patients with HCC and without HCC were recruited as cases and controls respectively. Using questionnaire, data was collected on patient characteristics; anthropometry measurements were done and biochemical test reports noted. Association between suspected risk factors and occurrence of HCC was determined by logistic regression.

Results: 220 ALD patients were enrolled. Mean age was 60.03 ± 9.161 years among cases and 52.70 ± 9.336 among controls; all were males. By univariable logistic regression, following factors had significant association with HCC development-age more than 60 years, family history of cancer, hepatitis C infection, diabetes mellitus, hypertension, smoking, alcohol consumption of more than 80 gram per day, daily, for at least 10 years. By multivariable logistic regression, the factors were-age more than 60 years (aOR 9.297, 95% CI: 2.941-29.385), hepatitis C infection (aOR 13.037, 1.494-113.803), smoking (aOR 2.572, 1.180-5.606), alcohol consumption of more than 80 gram per day, daily, for at least 10 years (aOR 2.233, 1.154-4.321)

Conclusion: Alcohol consumption more than 80 gram per day, daily, for at least 10 years; higher age, Hepatitis C infection and smoking increase predisposition of ALD patients to develop HCC. Vigorous screening, regular follow up and health education of ALD patients can aid early diagnosis and management.

The Impact of TIGAR on Tumor Microenvironment and Resistance to Ferroptosis in HCC

Katsuya Toshida1, Shinji Itoh1, Takuma Ishikawa1, Yuki Nakayama1, Yuriko Tsutsui1, Norifumi Iseda1, Takuma Izumi1, Yuki Bekki1, Shohei Yoshiya1, Takeo Toshima1, Tomoharu Yoshizumi1

1Department of Surgery and Science, Graduate School of Medical Sciences, Kyushu University Fukuoka Japan

Background: TP53-induced glycolysis and apoptosis regulator (TIGAR) is a p53 target protein that has critical roles in glycolysis and redox balance. The reports about the effect of TIGAR on prognosis and its biological role in hepatocellular carcinoma (HCC) are limited.

Methods: 386 patients with HCC who had undergone hepatic resection were enrolled. Immunohistochemical staining for TIGAR, cluster of differentiation (CD)8, CD68, programmed death-ligand 1 (PD-L1) and CD34 was performed. Additionally, the regulation of malignant activity and ferroptosis by TIGAR was investigated in vitro.

Results: Patients were divided into TIGAR-positive (n=80, 20.7%) and -negative (n=306, 79.3%) groups by immunohistochemical staining of TIGAR. In uni/multivariate analysis, TIGAR positivity was an independent prognostic factor (p<0.0001). In addition, TIGAR positivity was significantly associated with smaller number of CD8 positive T cells (p=0.0450), larger number of CD68 positive macrophages (p=0.0058), PD-L1 positive cases (p=0.0002) and vessels that encapsulate tumor cluster positive cases (p=0.0004). In vitro, TIGAR knockdown decreased cell motility (migration/invasion/colony forming abilities) and induced ferroptosis (down regulation of cell viability/elevation of reactive oxygen species and lipid peroxidation) (p<0.05). TIGAR knockdown inhibited the phosphorylation of adenosine monophosphate-activated protein kinase and acetyl-CoA carboxylase. Ferroptosis induced by TIGAR knockdown was inhibited by liproxstatin and baicalein treatment (p<0.05). The combination of TIGAR knockdown and lenvatinib significantly further induced ferroptosis (p<0.05).

Conclusions: High expression of TIGAR impacted the clinical outcome of HCC patients and TIGAR was associated not only with tumor microenvironment but also with resistance to ferroptosis.
Double knockout of P53/Pten induced an HCC mouse model shared a similar transcriptome to human HCC

Danjuan Lu1, Guiwen Guan1, Jing Yang2, Chia-Chen Chen1, Jing Zhang3, Zhao Chen4, Xuewei Qi1, Weilin Gu1, Abudurexiti Abulaiti4, Fengmin Lu1, Jingzhou Wang5, Yongzhen Liu6, Xiangmei Chen1

1Peking University Beijing China, 2Guangdong Provincial People’s Hospital Guangdong China, 3Beijing Tongren Hospital Beijing China, 4Qingdao University Shandong China, 5Shihezi University School of Medicine Xinjiang China, 6Princeton University Princeton USA

Background: HCC mouse models, play a vital role in studying the intricate interplay of factors contributing to HCC development. However, with a multitude of available HCC mouse models, choosing the one most closely resembles human HCC can be challenging. A comprehensive analysis of their characteristics and fidelity in recapitulating human disease is essential for selecting the most appropriate model for specific research objectives.

Methods: This study addresses this gap by conducting a comprehensive transcriptomic similarity analysis of widely used HCC mouse models. The researchers compared the gene expression profiles, immune microenvironments, and metabolic pathways of these models with those of human HCC.

Results: DENV-CC14-induced HCC model: Showed the worst similarity to human HCC in terms of transcriptome profiles and DEGs. Had minimal metabolic differences between tumor and non-tumor tissues.

p53&Pten KO model: Displayed a moderate level of similarity to human HCC in terms of transcriptome profiles and DEGs. Showed some enrichment of pathways similar to human HCC but also had unique enriched pathways.

HBV+p53&Pten KO model: Demonstrated the highest similarity to human HCC across various parameters. Shared a high degree of overlap in DEGs between tumor and non-tumor tissues with human HCC. Exhibited a transcriptome profile and immune cell infiltration pattern closely resembling human HCC. Showed metabolic alterations similar to those observed in human HCC.

Conclusion: This study highlights the importance of selecting appropriate HCC mouse models for research. The HBV+p53&Pten KO model emerged as the most promising model due to its remarkable similarity to human HCC across various aspects.

Immunophenotyping and tumor microenvironments of HBV-positive and negative hepatocellular carcinoma

Hongping Xia1

1National Cancer Centre Singapore Singapore Singapore

Background & aims: HBV infection leads to hepatocellular carcinoma (HCC) and affects immunotherapy. Exploring tumor ecosystem in HCC help to gain a deeper understanding and design more effective immunotherapy strategies for HCC patients with or without HBV infection.

Methods: Single-cell RNA sequencing (scRNA-seq) series were integrated as a discovery cohort to interrogate the tumor microenvironment (TME) of HBV+ HCC and HBV- HCC. We further dissect the intratumoral immune status of HBV+ and HBV- HCC. An independent cohort, including samples treated with immune checkpoint blockade therapy (ICB), was used to validate the major finding and investigate the effect of HBV infection on response to immunotherapy.

Results: The interrogation of TME indicated that TREG, exhausted CD8+ T cell and M1-like Macrophage MNP9 were enriched in HBV+ HCC, while MAIT was enriched in HBV- HCC. All subclusters of T cells showed high expression of immune checkpoint genes in HBV+ HCC. TREG cells enriched in HBV+ HCC also showed more robust immunosuppressive properties, which was confirmed by cross-talk between immune cell subsets. The ability of antigen presentation with major histocompatibility complex (MHC)-II was down-regulated in HBV+ HCC and this phenomenon can be reversed by immunotherapy. Two types of HCC also present different responses to immunotherapy.

Conclusion: There is a more immunosuppressive and exhausted TME in HBV+ HCC than in HBV- HCC. This in-depth immunophenotyping strategy is critical to understanding the impact of HBV along with the HCC immune microenvironment and helping to develop more effective treatments in HCC patients.

Prognostic impact of Cyber-Knife as part of multidisciplinary treatment in hepatocellular carcinoma

Takamasa Ohki1, 2

1Shioda Memorial Hospital Department of Cyber-knife Nagara Japan, 2Mistui Memorial Hospital Department of Gastroenterology Tokyo Japan

Backgrounds: Cyber-Knife (CK) is a stereotactic radiotherapy with high local control capability and is covered by insurance for the treatment of hepatocellular carcinoma (HCC) in Japan. We investigated the efficacy of CK as a multidisciplinary therapy in the treatment of HCC.

Methods: From January 2001 to December 2020, 568 patients with radically treated HCC were included. Of these, CK was added to 52 cases during the course of the study, and the remaining cases without CK were matched for age, gender, presence of HCV infection, tumor size, tumor number, ALBI score, and introduction of chemotherapy, and finally 40 cases each were selected to compare their backgrounds. The primary endpoint was overall survival (OS), and factors related to OS were also examined.

Results: The mean maximum tumor diameter and the mean number of tumors were 24 mm and 1.4, respectively, at the time of initial onset of HCC. The mean tumor diameter at the time of CK was 18 mm, and all the targets were one. The local control rate of CK was 96.8% at 1 year, 87.3% at 2 years, and 87.3% at 3 years. The overall survival rate from the initial treatment was 80.3% at 3 years, 70.8% at 5 years, and 39.1% at 10 years in the CK group, and 79.4% at 3 years, 52.9% at 5 years, and 22.7% at 10 years in the control group, with a significant difference (P = 0.047). In univariate analysis, ALBI score (HR 1.26 per 1 95%CI 1.08-1.48 P<0.01) and application of CK (HR 0.56 95%CI 0.32-0.99 P=0.049) were significant independent factors which contributed to OS.

Conclusion: Although it is difficult to determine the extent to which CK contributes to prolonged prognosis in a series of treatment courses, it was considered to be one of the effective treatments as a complement to standard treatment.

Abstract Submission No. 100244

Similar recurrence after curative treatment of HBV-related HCC, regardless of HBV replication
Background and Aims: Antiviral therapy (AVT) is required in patients with newly diagnosed hepatitis B virus (HBV)-related hepatocellular carcinoma (HCC), if HBV DNA is detectable. We compared the risk of recurrence according to HBV replication activity at the curative treatment of HBV-related HCC.

Methods: Patients with HBV-related HCC who underwent surgical resection or radiofrequency ablation between 2013 and 2018 were enrolled in this retrospective cohort study. Patients were categorized into two groups according to HBV replication activity at the curative treatment of HBV-related HCC (group 1: patients who met the AVT indication for HBV-related HCC due to detectable HBV DNA but did not meet the AVT indication if without HCC; group 2: patients who met the AVT indication, regardless of HCC).

Results: In the entire cohort (n=911), HCC recurred in 303 (33.3%) patients during a median follow-up of 4.7 years. After multivariate adjustment, group 2 showed a statistically similar risk of HCC recurrence (adjusted hazard ratio [aHR]=1.18, P=0.332) compared to that of group 1. In addition, group 2 showed statistically similar risks of early (<2 years; aHR=1.31) and late (≥2 years; aHR=0.83) recurrence than that of group 1 (all P<0.05). Propensity score matching and inverse probability of treatment weighting analysis also yielded similar risks of HCC recurrence between the two groups (all P>0.05, log-rank tests).

Conclusions: The risk of HCC recurrence in patients who received curative treatment for newly diagnosed HBV-related HCC was comparable regardless of HBV replication activity if AVT was properly initiated.

Abstract Submission No. 100371

Identifying optimal candidates for HAIC over Sorafenib: A systematic review and meta-analysis

TENGFEI SI1,2, Qing Shao2, Yun Ma1,2, Nigel Heaton1
1King’s College Hospital NHS Trust London United Kingdom
2King’s College London London United Kingdom

Background: Sorafenib is pivotal in extending the survival of patients with advanced or unresectable hepatocellular carcinoma (HCC) though its efficacy is largely curtailed by low response rates. With interest revived in hepatic artery infusion chemotherapy (HAIC), it was found that patients may receive greater benefit from HAIC compared to Sorafenib. This study aims to find optimal candidates for HAIC over Sorafenib.

Methods: A rigorous literature search was conducted to collect available studies comparing patients’ outcome differences between HAIC and Sorafenib. The pre-registered protocol was available at PROSPERO (CRD42023458845).

Results: A total of 26 studies with 6456 patients (HAIC:2648; Sorafenib:3808) were included. Chemotherapy-naïve patients (HR=0.66, 95%CI [0.56, 0.79]), individuals with Child-Pugh grade A liver reserve (HR=0.81, 95%CI [0.74, 0.89]), and those with major vessel invasion (MVI) but no extrahepatic metastasis (HR=0.58, 95%CI [0.45, 0.75]) could potentially benefit more by HAIC. However, for those who were refractory to trans-arterial chemoembolization (TACE), sorafenib demonstrated greater efficacy (HR=1.32, 95%CI [1.01,1.73]) while patients with extrahepatic metastasis whether with or without MVI (EHS+MVI+:HR=0.72, 95%CI [0.44, 1.17]; EHS+MVI-:HR=1.35, 95%CI [0.65, 2.84]) presented similar survival after HAIC or Sorafenib monotherapy. Additionally, pooling HRs from multivariate Cox regression showed that MVI, EHV, and AFP >400ng/ml could be independent risk factors for patients’ overall survival (OS), while HAIC treatment and lower BCLC stage were potentially protective factors.

Conclusions: Higher survival benefits could be expected from HAIC compared to sorafenib monotherapy in selected patients. A re-evaluation of HAIC as a potential treatment option in intermediate and advanced HCC is warranted.

Integrative translational research to study T cell exhaustion in hepatocellular carcinoma (HCC)

Da-Liang Ou1, Ching-Hung Hsieh1, Tzu-Yang Tseng2, Chia-Lang Hsu1,3, Bor-Sheng Ko4, Jr-Shiuian Lin5, Chien-Kuo Lee6, Hsueh-Fen Juan2, Chiu Hsu8
ASAP algorithm demonstrates high sensitivity for HCC surveillance - a prospective study.

Wei-Lun Liou1, Si-Yu Tan2, Fan Feng3, Kaina Chen1, Pik-Eu Chin-Pi n Ye o2, Chee-Kiat Tan1

1Department of Gastroenterology and Hepatology, Singapore General Hospital Singapore, 2Department of Clinical Pathology, Singapore General Hospital Singapore Singapore, 3Clinical Statistics Affair, Abbott Diagnostics USA USA, 4Medical & Scientific Research, Abbott Diagnostics Singapore Singapore

Background: Hepatocellular carcinoma (HCC) surveillance with liver ultrasound and alpha-fetoprotein (AFP) has limitations of accuracy and patients’ poor adherence with ultrasound examination. ASAP is a HCC risk algorithm based on Age, Sex, AFP, and Protein Induced by Vitamin K Antagonist-II (PIVKA-II) that may allow for a personalized surveillance protocol. We studied the performance of the ASAP algorithm in a prospective cohort of patients undergoing HCC surveillance.

Methods: Patients without prior HCC undergoing HCC surveillance in Singapore General Hospital Department of Gastroenterology and Hepatology and Department of Medical Oncology, National Taiwan University Hospital Taipei Taiwan, 5Department of Medical Oncology, National Taiwan University Hospital Cancer Center Taipei Taiwan, 6Department of Oncology, National Taiwan University Hospital Taipei Taiwan

Baseline AFP and PIVKA-II (Abbott ARCHITECT®) were assayed and prediction from the ASAP algorithm was calculated using the published model. The patients continued HCC surveillance with semi-annual ultrasound and AFP.

Results: There were 612 patients (60.9% male). Median age was 65 years (IQR 58-72). Most common liver disease was Hepatitis B (90%). By February 2023, after a median follow-up of 52.2 months (IQR 48.3-54.5), 15 patients developed HCC with 13 in BCLC stage 0/A. ASAP algorithm score had the highest AUROC (0.767) for HCC detection, compared to AFP or PIVKA-II alone (0.743 and 0.672 respectively). ASAP score’s sensitivity/specificity/negative predictive value (NPV)/AUROC for HCC developing within 1 and 2 years of biomarker assessment were 100%/87.3%/100%/0.946 and 85%/87.3%/99.8%/0.889, respectively.

Conclusion: ASAP algorithm demonstrated high sensitivity, specificity and NPV for HCC detection in a prospective cohort of patients undergoing HCC surveillance. Hence, in view of patients’ poor adherence to ultrasound imaging, substitution with regular assessment with the ASAP algorithm may be a feasible option.
Among those receiving Atezo+Bev therapy as first-line treatment (n = 152), 24 (15.8%) patients showed primary resistance, which was significantly associated with CRP, AFP, and DCP. The CRAFTITY score, incorporating CRP and AFP, effectively stratified the primary resistance rates (11.8%, 30%, and 66.7% for CRAFTITY scores of 0, 1, and 2 points, respectively).

**Conclusions:** About 15% of patients exhibited primary resistance to first-line Atezo+Bev therapy. The CRAFTITY score seemed useful to predict the likelihood of primary resistance.

---

**Association between Post-Ablation Fever and Prognosis in Initial Hepatocellular Carcinoma**

**Jie Yu**1, **Qian Cai**2, **Xin Hu**3

1Department of Interventional Ultrasound, Fifth Medical Center of Chinese PLA General Hospital Beijing China, 2Department of Interventional Ultrasound, Fifth Medical Center of Chinese PLA General Hospital Beijing China, 3Division of Transplantation Immunology, National Research Institute for Child Health and Development Tokyo Japan

**Background:** Fever, a common complication in patients with hepatocellular carcinoma (HCC) following thermal ablation, yet its impact on prognosis remains unclear.

**Materials and Methods:** This retrospective study included initial HCC patients who underwent percutaneous microwave ablation at 13 hospitals between January 2007 and February 2021. Statistical models were employed to identify the impact and cut-off values of post-ablation temperature and fever duration on early recurrence. Primary outcomes included very early recurrence (VER) and early recurrence (ER), and secondary outcomes were disease-free survival (DFS) and overall survival (OS) rates. Survival analyses used the Kaplan-Meier method.

**Results:** A total of 1458 BCLC stage 0-B HCC patients (mean age: 59 ± 11) with a median follow-up of 47 months. Compared to afebrile, patients who exhibited peak temperatures between 37.0–38.8°C and fever lasting 1-2 days (transient low-grade fever, TLF) showed independent protective effects against VER (HR, 0.73; 95% CI: 0.57, 0.95; P=0.017) and ER (HR, 0.66; 95% CI: 0.54, 0.81; P<0.001). Prolonged or high-grade fever (PHF) showed no differences in VER (P=0.964) and ER (P=0.171). Additionally, TLF patients displayed the highest 5-year DFS and OS rates of 42.6% and 73.2%, surpassing afebrile patients (33.2% and 69.3%, P=0.020 and 0.005) and PHF patients (44.1% and 66.7%, P=0.018 and <0.001). Notably, TLF patients exhibited the highest post-ablation lymphocyte counts increase (P<0.001 vs. afebrile and P=0.013 vs. PHF).

**Conclusions:** Transient low-grade fever following percutaneous microwave ablation in patients with hepatocellular carcinoma has demonstrated protective effects against early recurrence, possibly attributed to the activation of lymphocytes.

---

**Assessment of Cases with Prolonged Elevation of Tumor Markers without Detectable HCC Recurrence**

**Makoto Moriyama**1, **Ryosuke Tateishi**1, **Yuki Matsuhashita**1, **Tomoharu Yamada**1, **Takuma Nakatsuka**1, **Tatsuya Minami**1, **Masaya Sato**1, **Mitsuhiro Fujishiro**1, **Shuichiro Shiina**1, **Kazuhiko Koike**3

1Department of Gastroenterology, Tokyo University School of Medicine. Tokyo Japan, 2Department of Gastroenterology, Juntendo University Hospital, Faculty of Medicine, Juntendo University Tokyo Japan, 3Kanto Central Hospital, Public Health Mutual Aid Association Tokyo Japan

**Background:** Tumor marker elevation is highly predictive of hepatocellular carcinoma (HCC) recurrence during post-treatment surveillance. However, some patients show persistent tumor marker elevation without imaging evidence of recurrence.

**Methods:** We reviewed 1,610 patients with naive HCC treated with radiofrequency ablation in our department from 1999 to 2021. We identified cases in which tumor markers were continuously above the cutoff value for more than 180 days prior to HCC recurrence. The AFP cutoff value was set differently according to active viral hepatitis status.

**Results:** Inclusion criteria were met in 228 cases of recurrence in 172 patients, including AFP >20 ng/mL in 122 cases, AFP >200 ng/mL in 42, DCP >200 mAU/mL in 50, and AFP-L3 fraction >15% in 130. The average tumor size at recurrence was 1.7 cm, with 106 cases of solitary tumors, 74 with 2-3 tumors, and 33 with 4 or more tumors. Distant metastasis was observed in 8 cases (3 with neoplastic seeding, 3 with lymph node metastasis, and 2 with lung metastasis). Vascular invasion was observed in 7 cases (6 with portal vein and 1 with bile duct invasion). Treatment modalities included local therapy in 177 cases, transarterial chemoembolization in 36, resection in 6, systemic therapy in 4, best supportive care in 3, and others in 2. Local cure was achieved in 170 (74.6%).

**Conclusions:** In cases with tumor marker elevation prior to imaging, curative treatment was possible in the majority with caution for vascular invasion and distant metastasis.
those with post-LT HCC recurrence vs. without (4.2 [1.1] vs. 11.5 [9.6]), P<0.001).

Conclusions: Mean ICI cycles and withdrawal days pre-LT were associated with post-OLT outcomes. Prospective cohort studies and clinical trials are needed to determine the optimal strategy for using ICI before LT.

Improved Survival in BCLC 0/A HCC with Resection vs Ablation: A Propensity-Matched Multicentre Study

Jonathan Abdelmalak1, Simone Strasser2, Marie Sinclair3, Anouk Dev4, Zina Valaydon3, Jacinta Holmes4, Steven Bollipo2, Amanda Nicol5, Stephen Riordan6, Siddharth Sood9, Ammar Majeed1, Eileen Lam4, Elysia Greenhill4, John Zalcberg1, Stuart K Roberts4
1Alfred Hospital Melbourne Australia, 2Royal Prince Alfred Hospital Camperdown Australia, 3Austin Hospital Heidelberg Australia, 4Monash Health Clayton Australia, 5Western Health Footscray Australia, 6St Vincent’s Hospital Melbourne Fitzroy Australia, 7John Hunter Hospital New Lambton Heights Australia, 8Eastern Health Box Hill Australia, 9Princess of Wales Hospital Randwick Australia, 10Royal Melbourne Hospital Parkville Australia.

The optimal treatment approach in very-early and early-stage hepatocellular carcinoma (HCC) is not precisely defined, with ambiguity in the literature around the comparative efficacy of surgical resection versus ablation as curative therapies for limited disease. We performed this real-world propensity-matched, multicentre cohort study to assess for differences in survival outcomes between those undergoing resection and those receiving ablation. Patients with Barcelona Clinic Liver Cancer (BCLC) 0/A HCC first diagnosed between 01/01/2016 and 31/12/2020 who received ablation or resection as initial treatment were included in the study. A total of 450 patients were included in the study from 10 major liver centres including two transplant centres. Propensity-score matching was performed using age, sex, transplant centre, HBV, alcohol, diabetes, smoking, platelet count, Child Pugh Score, Charlson Comorbidity Index and tumour category (single tumour 2cm or less, 2-3cm, >3cm and multiple tumour), 156 patients were available for analysis with 78 in each group. Patients who underwent resection had significantly improved overall survival (log-rank test p=0.023, Figure 1) and local recurrence-free survival (log rank test p=0.027, Figure 2) compared to those who received ablation. Similar results were seen in unadjusted analysis of the original unmatched cohort (overall survival, log-rank test p=0.001; local-recurrence free survival p<0.001). Based on real-world data, our study supports the use of surgical resection in preference to ablation as first line curative therapy in appropriately selected BCLC 0/A HCC patients.

Chronological changes in clinical characteristics of HCC patients undergoing systemic therapy

Yoshinari Asoaka1,2, Ryosuke Tateishi1, Yasuhide Yamada1, Kiyoshi Hasegawa1, Hiroko Iijima2, Kengo Yoshimitsu4, Masayuki Kurosaki1, Michie Sakamoto4, Norihiro Kokudo2
1Teikyo University School of Medicine Tokyo Japan, 2National Center for Global Health and Medicine Tokyo Japan, 3Department of Gastroenterology, Graduate School of Medicine, The University of Tokyo, Tokyo Tokyo Japan, 4Hepato-Biliary-Pancreatic Surgery Division, Department of Surgery, Graduate School of Medicine, The University of Tokyo Tokyo Japan, 5Division of Hepatobiliary and Pancreatic Diseases, Department of Gastroenterology, Hyogo Medical University Nishinomiya Japan, 6Department of Radiology, Faculty of Medicine, Fukuoka University Fukuoka Japan, 7Department of Gastroenterology and Hepatology Musashino Red Cross Hospital Tokyo Japan, 8Department of Pathology, Keio University School of Medicine Tokyo Japan

Background: With the advancement in systemic therapy for hepatocellular carcinoma (HCC), the background of patients has significantly changed over time. In this study, we investigated the chronological change of the patients’ characteristics in Japan.

Methods: Hepatoma Registry of Integrating and Aggregating EHR (electric health record): HERITAGE study is a registry study of systemic therapy at member institutions of the Japan Liver Cancer Association (JLCA). Patients were divided into three groups based on the initiation dates of systemic therapy: April 2015-2017 (cohort A), 2018-2019 (cohort B), and 2020-March 2022 (cohort C). They were then compared in terms of age at the start of therapy, etiology, mALBI grade, presence of vascular invasion (VI), and existence of extrahepatic metastases (EHS).

Results: A total of 4,669 patients were enrolled, and the regimens were sorafenib/ lenvatinib/ atezolizumab plus bevacizumab in the following order: A 1415/0/0, B 346/1495/3, C 111/742/557. The percentage of patients aged 70 years or older was 57%, 66%, and 71% in cohorts A, B, and C, respectively. For non-viral cases, the corresponding percentages were 47%, 55%, and 58% in the same cohorts. The mALBI grade was 1 or 2a in 57%, 59%, and 61% of the patients in cohorts A, B, and C, respectively. Additionally, 39%, 53%, and 55% of patients in these groups had neither EHS nor VI.

Conclusion: There was an increase in the proportion of non-viral elderly patients among those eligible for systemic therapy. Advances of therapy have expanded the range of cases treated.

Abstract Submission No. 101101

Urban Rural Disparities at Presentation and Overall Survival of Hepatocellular Carcinoma in Taiwan

Chien-Hung Chen1,2, Yu-Jen Fang3, Rey-Heng Hu1,3, Ja-Der Liang4, Shib-Jer Hsu5, Po-Chin Liang2, Hong-Jen Hsieh1, Jo-Pai Chen1, Chiun Hsu6
1National Taiwan University Cancer Center Taipei City Taiwan, 2National Taiwan University Hospital Taipei City Taiwan, 3National Taiwan University Hospital Yunlin Branch Yunlin County Taiwan

Introduction: There are urban rural disparities in the management of hepatocellular carcinoma (HCC). The reasons are multifactorial. To investigate the degree of disparities, we initiated this study.

Methods: We assessed all HCC patients in the period of 2014 to 2019 from the database obtained from Integrative Medical Database, National Taiwan University Hospital (NTUH-MD). NTUH has a main campus located in Taipei City (urban) and Yunlin branch (NTUH-YL)(rural). Demographic characteristics, BCLC staging, underlying liver reserve (Child Pugh class, and ALBI score), viral etiology, treatment method, and overall survival were analyzed.

Results: A total of 3368 patients in NTUH and 785 patients in NTUH-YL were collected. NTUH had 50.9% of HCC patients presenting as BCLC stage 0 or A, while NTUH-YL had 41.1% in BCLC stage 0 or A. NTUH had 25.0% of HCC patients presenting as BCLC stage C or D, while NTUH-YL had 41.7% in BCLC stage C or D. ALBI grade 1 was found in 53.6% NTUH patients, while it was 33.6% in NTUH-YL.
Curative treatment (transplantation, resection, RFA) were done in 61.9% of NTUH patients, while it was 47.9% in NTUH-YL. The median overall survival (OS) was 63.2 months in NTUH and 38.5 months in NTUH-YL (p < 0.001).

Conclusions: There were significant disparities in the stage at presentation, underlaying liver reserve, treatment method, and median OS in HCC patients, between rural and urban areas even in the same medical system. To improve the OS in the rural HCC patients, earlier diagnosis is the urgent needs.

MOLECULAR CHARACTERIZATION OF HEPATOCELLULAR CARCINOMA IN ARMENIA, 2019-2020: INITIAL OBSERVATIONS

Hasmik Ghazinyan1-2, Pascal Pineau4, Soro Khemichyan3, Tigran Aghabekyan5, Tatevik Shahinyan2, Hayk Harutyunyan6
1Yerevan MSC Yerevan Armenia, 2Ecosense LLC Yerevan Armenia, 3Keck Medicine of USC LA USA, 4Institut Pasteur Paris France, 5Yerevan State Medical University Yerevan Armenia, 6Astghik MC Yerevan Armenia

Background: Within the large region encompassing the Caucasus, Middle East, and Central Asia, Armenia is the country where the incidence of liver cancer is the highest for both sexes.

Methods: A case-control study was conducted, and plasma samples were collected of 110 patients with hepatocellular carcinoma (HCC) and 167 patients with no tumor.

Results: HCV prevalence was 67.2% in the CLD group and 41.8% in the HCC and CLD group. HBV infection was less prevalent. Free circulating DNA was analyzed for a mutated TERT gene promoter.

Concerning HBV, 6 HCC patients were infected with subtype D1 (32%, n=8/25), and a single subtype 2a strain (4.0%).

Conclusion: Occult HBV is more prevalent than expected.

Abstract Submission No. 101242

Impact of complete tumor control, “so called cancer free”, in patients with advanced-stage HCC

Keisuke Koroki1, Sadahisa Ogasawara3, Tepppei Akatsuka1, Ryo Izai1, Chihiro Miwa1, Takuya Yonemoto1, Saee Yumita1, Masanori Inoue2, Kazufumi Kobayashi3, Soichi Kiyono3, Masato Nakamura1, Naoya Kanogawa1, Takayuki Kondo1, Shingo Nakamoto2, Naoya Kata1
1Department of Gastroenterology Graduate School of Chiba University Chiba city Japan

Background: As the advent of highly efficacious systemic therapies in hepatocellular carcinoma (HCC), there have been reports of successful conversions to states amenable to curative treatments. Our study ventures to shed light on the profound implications of reaching a cancer-free and examined the outcomes for those achieving a cancer-free following advanced-stage HCC.

Methods: We established a database tracking the full clinical course of all HCC patients (from 2003-June 2022). We identified the initial instances of MVI or EHM. In this study, “Cancer Free” was defined by the following criteria. 1) Surgical cases: The absence of tumors and no recurrence in two distinct imaging evaluations spaced a minimum of two months apart. 2) Non-surgical cases: Two consecutive imaging evaluations (a minimum of two months apart) showed no tumors, with both evaluations indicating a complete response (CR) as per mRECIST.

Results: We identified 815 advanced-stage HCC patients. The cancer free rate was 8.6% (70/815). The median OS of patients who achieved cancer free was not reached (95% CI: 67.4-NA), and that of patients who did not achieve cancer free was 11.4 months (95% CI:9.5-13.7) (p<0.001). In the decision tree analysis in patients without extrahepatic metastatic spread, the number of tumors ≥8 was the strongest factor making it difficult to achieve cancer free.

Conclusions: The frequency of cancer free is low in the advanced-stage HCC. However, the OS is significantly longer in the patients who achieve it. Achievement is related to the number of intrahepatic tumors.
Systemic therapies for patients with intermediate stage HCC and the evolution of the prognosis

Systemic therapies for patients with intermediate stage HCC and the evolution of the prognosis

Background: Systemic therapies for TACE-refractory/unsuitable patients in intermediate-stage hepatocellular carcinoma (HCC) has been discussed. However, the extent to which these treatment strategies have improved the prognosis of patients with intermediate-stage HCC, a heterogeneous population, has not been adequately investigated.

Methods: We reviewed the treatment outcomes of intermediate-stage HCC diagnosed at our hospital from 2004 to 2022. Patients were divided into three groups according to the date of diagnosis (period I: 2004-April 2009, period II: May 2009-August 2018, and period III: September 2018-2022). The classification was based on the time of approval of sorafenib and lenvatinib in Japan. Prognostic evolution of TACE-refractory/unsuitable patients was evaluated. We defined cancer-free as 6 months without recurrence and evaluated the evolution of the cancer-free rate.

Results: Of all 916 intermediate-stage HCC patients the frequency with which systemic therapy was initiated at the time of diagnosis has increased over time. As for TACE unsuitable, in patients with tumors number ≥8, there was a trend toward improved survival in period III.

Conclusions: We clarified the expression of core genes and the mechanism of immune infiltration, and provided a new direction for the identification of HCC prognostic markers and the potential targeting of Traditional Chinese medicine.

Analysis of atezolizumab antidrug antibody in HCC patients treated with atezolizumab and bevacizumab

Keishi Ouchi, Jun Inoue, Masashi Ninomiya, Akitoshi Sano, Mio Tsuruoka, Kosuke Sato, Masazumi Onuki, Satoko Sawahashi, Atsushi Masamune

Abstract Submission No. 101341

O-0598

Analysis of atezolizumab antidrug antibody in HCC patients treated with atezolizumab and bevacizumab

Backgrounds: Atezolizumab (Atezo)+Bev (Bevacizumab) (Atezo+Bev) is positioned as first-line chemotherapy for unresectable hepatocellular carcinoma (HCC). Although immune checkpoint inhibitors (ICIs) may induce an antidrug antibody (ADA), there is a lack of evidence for the relationship between ADA against Atezo (ATZ-ADA) levels and treatment outcome. In this study, we assayed ATZ-ADA levels and analyzed its association with therapeutic outcome in advanced HCC patients who were treated with Atezo+Bev.

Methods: Twenty-six patients with unresectable HCC treated with Atezo+Bev between 2020 and 2023 were included in this study. ATZ-ADA was assayed with ELISA using the stored serum samples at the time of 3 courses of treatment or the earliest time point.

Results: The backgrounds of 26 patients were as follows: male/female=8/18, median age 74 years, HCV/HBV/non B,C=7/7/12, BCLC stage B/C=16/10, Child-Pugh score 5/6=18/8, ALBI grade 1/2=7/19. Atezo+Bev was administered for a median of 4 courses, and the best responses with mRECIST were CR/PR/SD/PD=2/11/7/6. ATZ-ADA levels were assayed at 3/4/6/7/12/13-20 course administration (12/7/3/4 cases, respectively). The median ADA level (OD value) was 0.035 and did not correlate with the number of treatment courses. The median ADA level in each response group was CR/PR/SD/PD=0.031/0.035/0.036/0.038. Interestingly, a PD patient had the highest ATZ-ADA level (0.079). His treatment was switched to the STRIDE regimen with Tremelimumab+Durvalumab resulting in CR.

Conclusions: The ATZ-ADA levels in this study were generally low, suggesting the proportion of patients in whom ADA inhibited the therapeutic effect was small. It was suggested that patients with high ATZ-ADA should consider treatment switch as soon as possible.
Increased spleen volume during atezolizumab and bevacizumab: Predictive factors and clinical outcome

Takeshi Hatanaka1,10, Satoru Kazikazi2,10, Atsushi Hiraoka3,10, Kazuya Kariyama4,10, Toshifumi Tada5,10, Hidenori Toyoda6,10, Atsushi Naganuma8, Koichi Takaguchi10, Yutaka Yata10, Kazuhiro Kawata10, Tomomitsu Matono10, Joji Tani10, Takashi Kumada10

Background: We previously reported a greater increased spleen volume in hepatocellular carcinoma (HCC) patients receiving atezolizumab plus bevacizumab (Atez/Bev) compared to lenvatinib (Oncology 2023). In malignant cases treated with immune checkpoint inhibitor, baseline spleen volume (SpV) and alternations in SpV were negatively associated with PFS and OS. The study aimed to investigate the relationship between changes in SpV and therapeutic outcome of Atez/Bev. Additionally, we also investigate the predictive factors associated with increased SpV.

Methods: This retrospective study included 164 HCC patients who did not have portal vein tumor thrombosis or a history of splenectomy or partial splenic embolization. SpV were calculated based on CT imaging and patient characteristic imbalances were adjusted by IPTW method.

Results: The median ages were 74 (IQR 68-80), with 135 (82.3%) patients being male. Baseline SpV was 184.6 (IQR 130.3-256.9) cm3. Enlarged SpV at baseline (>184cm3) were not significantly associated with PFS and OS in both crude and IPTW-weighted cohort. SpV increased in 100 (84.0%) patients during Atez/Bev treatment. In 119 patients who obtained CT imaging from 3 to 4 month after treatment, the median difference in SpV were 25cm3 (IQR 6-59). Predictive factors for increased SpV (>25cm3) included age, BCLC A or B, and FIB-4 index. Patients with greater changes in SpV (>25cm3) were not associated with the PFS and OS in both crude and IPTW-weighted cohort.

Conclusions: Enlarged baseline SpV and greater changes in SpV were not associated with the therapeutic outcomes of Atez/Bev. Alternation in SpV may be associated with liver fibrosis.

Abstract Submission No. 101561

Single-cell profiling of the circulating immune cell predicts the immunotherapy for HCC

Akira Nishio1, Takahiro Kodama1, Akira Doi1, Yuki Tahata1, Kunimaro Furuta1, Hayato Hikita1, Tomohide Tatsunami1, Tetsuo Takehara1

1Department of Gastroenterology and Hepatology, Osaka University, Graduate School of Medicine Suita Japan

Background: The combination of Atezolizumab and Bevacizumab (Ate/Bev) has revolutionized the clinical outcome for unresectable hepatocellular carcinoma (HCC), which has been shown to be superior to sorafenib in IMbrave150 trial. However, how to predict the response to Ate/Bev therapy in HCC patients remains elusive. Herein we investigated the circulating immune profile of patients with unresectable HCC receiving Ate/Bev therapy.

Methods: HCC patients were enrolled in a prospectively registered multicenter study and peripheral blood mononuclear cells (PBMCs) were collected from these patients treated with Ate/Bev. Single cell-RNA sequence was utilized to analyze PBMCs from 5 responders and 5 non-responders at pretreatment and 6 weeks after Ate/Bev therapy.

Results: First, 231,832 cells of 20 PBMCs from 10 patients were clustered into 30 subsets and annotated based on the gene expression in each cluster. Responders showed the higher frequencies of central memory CD4 T cells and B cells compared to non-responders at pretreatment (p= 0.0315, 0.0159, respectively), while non-responders showed the higher frequencies of monocytes than responders (p= 0.0315). The frequency of CD8 T cells was not significantly different between groups, but responder showed stronger expression of cytotoxicity-related genes in CD8 T cells compared to non-responders. Re-clustering of monocytes resulted in 7 types of subclusters, exhibiting the differential dynamic changes during Ate/Bev treatment.

Conclusion: The immune profiling of PBMCs potentially predicts the response to checkpoint inhibitors in patients with unresectable HCC.
Impact of genetic discrimination between MC and IM on the prognosis of recurrent HCC

Yuji Iimuro1, Atsushi Takano1, Kenji Amemiya2, Yosuke Hirotsu3, Hitoshi Mochizuki4, Shuntaro Ohi1,5, Masao Omata6
1Department of Surgery, Yamanshi Central Hospital Kofu Japan, 2Genome Analysis Center, Yamanshi Central Hospital Kofu Japan, 3Department of Medicine, Yamanshi Central Hospital Kofu Japan, 4Department of Medicine, Teikyo University Chiba Medical Center Chiba Japan, 5The University of Tokyo Tokyo Japan

During the follow-up after HCC resection, genetic mutation patterns possibly change from multicentric occurrence (MC) to intrahepatic metastasis (IM), or vice versa, along with the recurrence. In the present study, we focused on patients who underwent repeated resection for recurrence and analyzed the prognosis along with the genetic mutation change.

Methods: We performed genomic analysis using an in-house HCC panel employing NGS for 200 cases of liver resection, involving 350 lesions. Among the 200 cases, we sequentially performed genetic discrimination (MC/IM) between the primary and recurrent nodules in 30 cases that underwent liver resection for recurrence.

Results: Among the 30 cases (primarily 18 solitary, 12 multifocal), there were 17 MC- and 13 IM-recurrence. Significantly better OS was detected in MC-recurrent cases compared to IM ones (p=0.025). Among primarily MC multifocal HCC (n=8) whose OS was significantly better than that in IM ones, 2 cases experienced IM-recurrence, and one had a poor prognosis, while another survived without recurrence. Meanwhile, 1 MC- and 3 IM-recurrence were observed among the 4 primarily IM multifocal HCC, with poor prognosis in all cases, suggesting a dismal impact of primary IM. Among the 13 IM-recurrent cases, the genetic change from IM to MC was seen in one case after a long tumor-free status, while the other cases experienced relatively poor prognosis.

Discussion: Genetic IM in primarily multifocal HCC and recurrent HCC implies a poor prognosis, suggesting the need for early drug introduction. MC-recurrence after a long tumor-free status is a good marker even in IM-recurrent cases.

Results: The median ages were 74 years (IQR 68.8-80.0), with 745 patients (78.9%) being male. Chronic liver diseases were HCV in 318 (33.7%), HBV in 156 (16.5%), HBV plus HCV in 1 (0.1%), alcohol in 209 (22.1%), and other causes in 260 (27.5%) patients. mALBI grade was 1, 2a, and 2b in 335 (35.5%), 244 (25.8%), and 350 (37.1%), and 15 (1.6%) patients, respectively. BCLC stage distribution was very early, early, intermediate, advanced, and terminal in 19 (2.0%), 54 (5.7%), 370 (39.2%), 485 (51.4%), and 16 (1.6%) patients, respectively. Conversion therapy was conducted in 40 (4.2%) patients, involving resection (n=7), ablation therapy (n=24), TACE (n=14), and radiation therapy (n=1), with treatment modalities overlapping. The objective response rates assessed by mRECIST were 75.0% and 34.0% in the conversion group and non-conversion group, with a statistical significance (p<0.001) The median overall survival (OS) was not reached in the conversion group, with a 1-year survival rate of 97.4%, and was 20.4 months in the non-conversion group, showing statistical significance (p<0.001). BCLC stage B was identified as a predictive factor associated with conversion therapy.

Conclusions: Patients with BCLC intermediate-stage HCC were likely to received conversion therapy and patients receiving conversion therapy achieved favorable clinical outcomes.

Conversion therapy for unresectable HCC in 944 patients following atezolizumab and bevacizumab

Takeshi Hatanaka1, 2, Satoru Kakizaki2, Atsushi Hiraoka2, Kazuya Kariyama2, Toshifumi Tada2, Hidenori Toyoda2, Ei Itobayashi2, Joji Tani2, Kunihiko Tsuji2, Ohama Hideko2, Kazunari Tanaka2, Masaki Kaibori2, Hidekatsu Kuromi2, Masatoshi Kudo2, Takashi Kumada2
1Department of Gastroenterology, Gunna Saiseikai Maebashi Hospital Maebashi Japan, 2RELPEC/HCC 48 group Ogaki Japan

Background: This study aimed to investigate the clinical outcome of conversion therapy following atezolizumab and bevacizumab (Atez/Bev).

Methods: A total of 944 hepatocellular carcinoma (HCC) patients who underwent liver resection for recurrence were included in this study.

Results: Patients with BCLC intermediate-stage HCC were likely to received conversion therapy and patients receiving conversion therapy achieved favorable clinical outcomes.
Prescription patterns of sorafenib and the following salvage treatment for advanced HCC in Taiwan

Chien-Huai Chiang1, Ching-Hu Chung2, Rick Chen3, Yun-Chun Wu4, Yu Yun Shao5

1National Taiwan University Cancer Center Taipei City, Taiwan, 2Mackay Medical College New Taipei City Taiwan, 3Roche Taipei City Taiwan, 4National Taiwan University Hospital Taipei City Taiwan

Background: Sorafenib (SOR) was covered by National Health Insurance (NHI) since 2012. Two expansions in reimbursement and the introduction of salvage therapy post-SOR failure in 2019 Jun 1 have altered the treatment landscape. This study explores the prescription patterns in Taiwanese HCC patients.

Methods: Using the NHI database, we analyzed patients receiving their first prescription between Aug 1, 2012, and Dec 31, 2021. Patients were divided into 3 cohorts based on prescription dates: 1st cohort (before Oct 31, 2016) with extrahepatic spread or main/first branch portal vein (PV) thrombosis; 2nd cohort (Nov 1, 2016 to May 31, 2019) including BCLC B post 3 locoregional therapies (LRTs) within 6 months; 3rd cohort (after Jun 1, 2019) encompassing patients with PVTT, first/third/third branch of PV and BCLC B post 3 LRTs within 12 months.

Results: 19,806 patients were included. LRTs were performed during the SOR in 5133 (25.9%) patients, TACE (n = 4343, 21.9%) as the most common. Fewer patients initially received standard SOR dose (1st vs. 2nd vs. 3rd cohort: 54.9% vs. 46.5% vs. 36.3%). The median OS was 6.1, 7.9, and 10.4 months for the 1st, 2nd, and 3rd cohort, respectively (p < 0.001). Salvage with SOR failure and Child A was reimbursed, 2264 patients discontinued SOR. Among them, 1323 (58.4%) received salvage therapy, including regorafenib, ramucirumab, and nivolumab, the median treatment duration of which was 3.3, 2.6, and 3.9 months, respectively.

Conclusions: Physicians often initiate lower doses of multikinase inhibitors. Less than 60% of patients received salvage therapy. There remains a significant unmet need for novel therapies.

Increased PD-1+TIGIT+ TIM-3+ in peripheral circulating cells predict poor prognosis of HCC patients

Xiaoli Liu1, Yaxian Kong2, Huiwen Yan1, Libua Yu1, Yixin Hou1, Xianbo Wang1, Yuyong Jiang1, Zhiyun Yang1

1Center for Integrative Medicine, Beijing Ditan Hospital, Capital Medical University Beijing China, 2Institute of Infectious Diseases, Beijing Ditan Hospital, Capital Medical University Beijing China

Background: Previous studies had shown that co-inhibitory molecules were associated with tumor prognosis, but whether their co-expression is related with tumor outcome remains unclear. This study was to explore the relationship between the co-expression of co-inhibitory molecules and the progression and death of patients with hepatocellular carcinoma(HCC).

Methods: We prospectively enrolled 299 patients with HCC of whom 17 HCC patients with hepatectomy. We detected the expression levels of coinhibitory molecules on the surface of peripheral blood mononuclear cells(PBMC) and tumor-infiltrating T cells(TILs). Then clinical indicators and co-inhibitory molecular expression were incorporated into Cox regression to analyze the impact on progression and death of HCC.

Results: The proportion of CD8+PD-1+TIGIT+TIM-3+T cells in TILs was higher than that in PBMC, and the level was positively correlated with peripheral blood level(r=0.71, P=0.003). COX multivariate regression analysis showed that, PVTTHR=1.77, neutrophil-to-lymphocyte ratio(HR=1.14), γ-GGT(HR=1.02), tumor size≥5cm(HR=1.76), proportion of CD8+PD-1+TIGIT+TIM-3+T cells(HR=1.12) were independent risk factors for survival of HCC patients, albumin(HR=0.96) was an independent protective factor. Compared with low level of CD8+PD-1+TIGIT+TIM-3+T cells, the hazard ratios of 3-year overall survival of high-level group were 1.88 in the KM analysis.

Conclusion: High levels of CD8+PD-1+TIGIT+TIM-3+T cells was associated with poor outcome of HCC, which can be contribute to assess the prognosis of HCC and provide theoretical basis for multi-target immune checkpoint synergistic therapy in the future.
The efficacy and safety of durvalumab + tremelimumab for unresectable hepatocellular carcinoma

Shinsuke Uchikawa1, Tomokazu Kawaoka1, Kenji Yamaoka1, Yasutoshi Fujii1, Hatsue Fujino1, Atsushi Ono1, Takashi Nakahara1, Eiuke Murakami1, Daiki Miki1, Masataka Tsuge1, Shiro Oka1
1Hiroshima university hospital, department of gastroenterology Hiroshima Japan

**Background:** In recent years, durvalumab + tremelimumab combination therapy (Dur+Tre) was approved for unresectable hepatocellular carcinoma (uHCC).

**Method:** Forty-two cases of Child-Pugh A who received Dur+Tre for uHCC from April to October 2023 were enrolled. The background was as follows. Male/Female: 38/4, median age 73 years, HBV/HCV/NBNC: 11/8/23, first line 16 cases, extrahepatic metastasis positive 17 cases, macroscopic vascular invasion positive 8 cases, BCLC 0/A/B/C: 1/3/17/21, Child-Pugh score 5/6: 30/12, mALBI grade 1/2a/2b: 24/8/10, AFP 30.3 ng/ml and PIVKA-2 528.5 mAU/ml (median values). The administration method was the STRIDE regimen.

**Results:** The efficacy and safety were investigated.

**Conclusion:** Dur+Tre is effective as a first-line systemic therapy for uHCC. On the other hand, severe immune-mediated adverse event (imAE) occurred in some cases, we need to pay attention to the occurrence of imAE.

---

Liver regeneration following partial hepatectomy in hepatocellular carcinoma: not only size matters

Haiyi Long1, Jiayao Huang1, Qingyu Wu1, Manxia Lin1
1Division of Interventional Ultrasound, Department of Medical Ultrasound, The First Affiliated Hospital, Sun Yat-sen University Guangzhou China

**Background:** To investigate factors associated with liver regeneration capacity in patients with hepatocellular carcinoma (HCC) after liver resection (LR).

**Methods:** A total of 123 patients with HCC who underwent liver stiffness (LS) by shear wave elastography (SWE) prior to LR were retrospectively included. The future liver remnant (FLR) prior to LR, and postoperative liver remnant (PLR) after LR were measured. The standardized future liver remnant (sFLR), parenchymal hepatic resection rate (PHRR), and regeneration index (RI) were calculated. Patients were classified into two subgroups based on the extent of LR: low PHRR (<50%) and high PHRR (>50%). Spearman correlation analysis was used to investigate factors associated with RI, and receiver operating characteristic (ROC) curve was employed to evaluate the diagnostic performance of these relative factors to predict a significant liver regeneration (RI>1).

**Results:** Strong correlation between RI and volume-related parameters, including FLR (r=-0.754, p<0.001) and sFLR (r=-0.811, p<0.001), were identified. Optimal cutoff values of 535ml for FLR and 0.452 for sFLR were used to predict a significant liver regeneration with an area under the curve (AUC) value of 0.967 and 0.980, respectively (all p<0.001). In the high PHRR subgroup, LS was the only non-volume parameter correlating with RI (r=-0.526, p=0.012). A cutoff value of 6.7kPa was used to predict a significant liver regeneration with an AUC value of 0.767 (p=0.035).

**Conclusions:** The remnant volume was the key to liver regeneration after LR for HCC. LS may serve as a potential predictor for liver regeneration in those with extensive loss of parenchymal.

---

Decoding HCC Survival: A Comparative Analysis of Early vs. Late-Onset Cases

Chyntia Olivia Maurine Jasirwan1, Ibrahim Achmad2, Wulyo Rajabto1, Murdani Abdulullah1
1Hepatobiliary Division, Department of Internal Medicine, Cipto Mangunkusumo Hospital, Faculty of Medicine, Universitas Indonesia Jakarta Indonesia, 2Department of Internal Medicine, Cipto Mangunkusumo Hospital Jakarta Indonesia, 3Hematology and Medical Oncology Division, Department of Internal Medicine, Cipto Mangunkusumo Hospital, Faculty of Medicine, Universitas Indonesia Jakarta Indonesia, 4Gastroenterology Division, Department of Internal Medicine, Cipto Mangunkusumo Hospital, Faculty of Medicine, Universitas Indonesia Jakarta Indonesia

**Background:** Hepatocellular Carcinoma (HCC) often has a grim prognosis, with most cases diagnosed at advanced stages. Intriguingly, younger individuals tend to show higher prevalence and poorer outcomes.

**Objectives:** This study aims to compare survival rates between early and late-onset HCC patients at RSCM and identify factors influencing their survival.

**Methods:** A retrospective cohort study was conducted on HCC patients from Cipto Mangunkusumo Hospital’s registry (2015-2022). Kaplan-Meier curves depicted survival, while Cox Proportional Hazard Regression with a backward method identified independent prognostic factors.

**Results:** Among 896 subjects, early onset patients had a median survival of 2 months (95% CI: 1.071-2.929), significantly lower than the 4 months (95% CI: 3.441-4.559) in late-onset patients (p=0.021). Early onset showed a higher event rate at 24 months (92.9%) compared to late onset (87.7%) (p=0.032). Multivariate analysis revealed hypertension (HR: 3.728) and lack of hepatitis treatment (HR: 2.48; p=0.053) as key factors in early onset survival. In late-onset cases, AFP levels ≥200 ng/mL (HR: 1.28), AJCC stage (highest risk at stage 4, HR: 4.52), supportive, and palliative therapies (HR: 5.23 and 1.66, respectively) were significant.

**Conclusion:** Early onset HCC patients have a median survival of 2 months, half of that in late-onset patients. Distinct prognostic factors were identified in each group, highlighting the need for tailored approaches in managing early and late-onset HCC.

**Keywords:** Survival, Early Onset, Late Onset, Hepatocellular Carcinoma

Utility of Lens culinaris agglutinin-reactive AFP (AFP-L3) in atezolizumab plus bevacizumab therapy

Yutaka Yasui1, Kaoru Tsuchiya1, Yuadai Yamazaki2, Michiko Yamada1, Taisei Keitoku1, Risa Okada1, Mayu Higuchi2, Kenta Takaura1, Shohei Tanaka1, Chiaki Maeyashiki1, Nobuharu Tamaki1, Yuka Takahashi1, Hiroaki Nakanishi1, Masayuki Kuroskai1, Namiki Izumi1

1Department of Gastroenterology and Hepatology, Musashino Red Cross Hospital Tokyo Japan

Background: While combined immunotherapy has become the first-line treatment for unresectable hepatocellular carcinoma, there is an unmet need to identify biomarkers to determine efficacy during treatment. Lens culinaris agglutinin-reactive alpha-fetoprotein (AFP-L3) has been reported to be useful in the diagnosis of hepatocellular carcinoma and in predicting prognosis after transplantation or resection. This study aimed to clarify whether baseline AFP-L3 and its dynamics during the treatment are useful in predicting response to systemic therapy.

Methods: We enrolled 151 patients with unresectable hepatocellular carcinoma who received atezolizumab plus bevacizumab treatment. The radiological response was assessed by RECIST ver 1.1 at 6-8 weeks and every 8-12 weeks after that. Progression-free survival (PFS) was analyzed by the Kaplan-Meier method.

Results: Patients had a median age of 74 years, 116 were male, 51 had HCV as background liver disease, and 98 received treatment as the first-line therapy. The median PFS was 6.6 months. At baseline, AFP-L3 was not elevated (<0.5%) in 26(17%) patients and median value of AFP-L3 was 14.5%. Patients with AFP-L3<14.5% (n=70) showed significantly longer PFS (8.7 vs 4.6 months, p=0.009). Among 106 patients with AFP-L3<0.5% at baseline, AFP-L3 decreased below 80% within 6 weeks compared to the baseline in 19 (18%) patients (AFP-L3 response). Patients who achieved AFP-L3 response showed significantly better PFS than those without (14.4 vs 5.1 months, p=0.04). A similar tendency was seen in patients with baseline AFP<400ng/ml (p=0.07); however, in patients whose baseline AFP ≥400ng/ml, the difference was insignificant since only two patients achieved AFP-L3 response.

Conclusion: AFP-L3 was useful in predicting PFS of patients who received atezolizumab plus bevacizumab treatment. AFP-L3 response was a useful on-treatment biomarker for patients whose baseline AFP-L3 is elevated at baseline.

Trends and forecast mortality of liver cancer to 2040 in the United States: A population-based study

Sikai Qiu1, Jiangying Cai2, Xinyuan He4, Zhanpeng Yang3, Jian Zuo1, Yee Hui Yeo5, Fanpu Ji6, Mindie H Nguyen7,8

1The Second Affiliated Hospital of Xi’an Jiaotong University Xi’an China, 2Lanzhou University Second Hospital Lanzhou China, 3Xi’an Jiaotong University Xi’an China, 4Cedars-Sinai Medical Center Los Angeles United States, 5National & Local Joint Engineering Research Center of Biodiagnosis and Biotherapy, The Second Affiliated Hospital of Xi’an Jiaotong University Xi’an China, 6Xi’an Jiaotong University, Ministry of Education of China Xi’an China, 7Stanford University Medical Center Palo Alto United States, 8Stanford University Palo Alto United States

Objective: The burden of liver cancer varies across the world. Herein, we present updated estimates of the burden of liver cancer mortality in the United States (US) and provide predictions of age-standardized mortality rates (ASMR) to 2040.

Methods: Using CDC WONDER of the NVSS, we estimated the ASMR of liver cancer during 2006-2040. We used joinpoint regression to assess the trend of mortality. Prophet/ARIMA prediction modeling analysis based on trends from 2006-2022, we predicted mortality for 2023-2040 and stratified by etiology and sex.

Results: Among the 333,784 liver cancer-related deaths during 2006-2022, we found increasing annual percentage change(APC) of 2.8% and 0.6% for 2006-2013 and 2013-2016, followed by stable mortality trends, and observed ASMR (per100,000 persons) 8.31 in 2022 overall. By sex, the APC for 2019-2022 for female is 2.7%(95%CI1.7-4.3) and the ASMR will increase to 4.86 in 2040 compared with 4.46 in 2022. However, the APC for 2015-2022 for male is -0.8%(95%CI-1.4-0.4) and the ASMR will decrease to 10.86 in 2040 compared with 12.75 in 2022(Fig.1A). By etiology, HCV-related mortality reached a peak in 2015 and decreased rapidly after that. The ASMR rise was most pronounced in alcohol-associated liver disease (ALD) and non-alcoholic fatty liver disease (NAFLD), especially ALD-related deaths will be to the leading cause of liver cancer deaths in 2026(Fig.1B/C). The proportion of ALD and NAFLD-related liver cancer deaths sharply rise during 2006-2022(Fig.1D).

Conclusions: ASMR for ALD and NAFLD increased at alarming rates during 2006-2022 in US with the fastest rise in ALD-related liver cancer.

Impact of Methylated SEPT9 Liquid Biopsy Test as a Prognostic Biomarker in Hepatocellular Carcinoma

Issei Saeki1, Takahiro Yamasaki2, Maho Egusa4, Norikazu Tanabe1, Yuki Kunimune2, Yuatuka Suehiro1, Taro Takami1

1Department of Gastroenterology of Hepatology, Yamaguchi University Graduate School of Medicine Yamaguchi Japan, 2Department of Laboratory Medicine and Oncology, Yamaguchi University Graduate School of Medicine Yamaguchi Japan

Objective: Several biomarkers are used for cancer diagnosis, treatment monitoring, and prognostic prediction. In hepatocellular carcinoma (HCC), the classical tumor marker, AFP is used as a diagnostic and monitoring marker. We have reported liquid biopsy based on a methylated SEPT9 (m-SEPT9) as a new candidate of HCC diagnostic and monitoring marker (Hepatol Commun. 2020). In this study, we investigated the significance of m-SEPT9 as a prognostic biomarker.

Methods: We enrolled 787 HCC patients obtained from multi-centers during 2018-22. We measured m-SEPT9 using “combined restriction digital PCR assay” which was developed by us and examined its potential as a prognostic biomarker.

Results: The median age was 73 years with 563 males (71.5%). BCLC stages 0, A, B, C, and D were 107, 250, 138, 268, and 21 patients, respectively and Child-Pugh A, B, and C were 669, 101, and 14 patients, respectively. The multivariate analysis showed that AFP, DCP, and m-SEPT9 were independent prognostic predictors in addition to Child-Pugh and BCLC stage in overall HCC patients. Furthermore, Child-Pugh, m-SEPT9, and AFP were significant independent prognostic predictors in the BCLC C-D group, whereas Child-Pugh and AFP were extracted in the BCLC 0-B group. AFP and m-SEPT9 were independent prognostic markers in advanced stage. The patients with advanced HCC were stratified according to the combination of m-SEPT9 and AFP.
Conclusion: The m-SEPT9 liquid biopsy test has a great potential for a prognostic biomarker of HCC.

ICIs and anti-VEGF antibody/TKIs with or without TACE as First-line Treatment for Advanced HCC

Zhicheng Jin1, Jian-Jian Chen1, Bin-Yan Zhong1, Hai-Dong Zhu1, Zheng-Gang Ren2, Gao-Jun Teng1, Hai-Tao Zhao1

1Center of Interventional Radiology and Vascular surgery, Department of Radiology, Zhongda hospital, Southeast university Nanjing China, 2Department of Interventional Radiology, The First Affiliated Hospital of Soochow University, Soochow University Suzhou China, 3Department of Hepatic Oncology, Liver Cancer Institute, Zhongshan Hospital, Fudan University Shanghai China, 4Department of Liver Surgery, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing Beijjing China

Background: The role of transarterial chemoembolization (TACE) in the treatment for advanced hepatocellular carcinoma (HCC) is unconfirmed. This study aimed to assess the efficacy and safety of immune checkpoint inhibitors (ICIs) plus anti-vascular endothelial growth factor (anti-VEGF) antibody/tyrosine kinase inhibitors (TKIs) with or without TACE as first-line treatment for advanced HCC.

Methods: This nationwide, multicenter, cohort study included advanced HCC patients receiving either TACE with ICIs plus anti-VEGF antibody/TKIs (TACE-ICI-VEGF) or only ICIs plus anti-VEGF antibody/TKIs (ICI-VEGF) from January 2018 to December 2022. The study design followed the target trial emulation framework with stabilized inverse probability of treatment weighting (sIPTW) to minimize biases. The primary outcome was overall survival (OS). Secondary outcomes included progression-free survival (PFS), objective response rate (ORR), and safety. The study is registered with ClinicalTrials.gov, NCT03132821.

Results: Among 1244 patients included in the analysis, 802 (64.5%) patients received TACE-ICI-VEGF treatment and 442 (35.5%) patients received ICI-VEGF treatment. The median follow-up time was 21.1 months and 20.6 months, respectively. Post-application of sIPTW, baseline characteristics were well-balanced between the two groups. TACE-ICI-VEGF group exhibited a significantly improved median OS (22.6 months [95%CI: 21.2-23.9] vs 15.9 months [14.9-17.8]; adjusted hazard ratio [aHR] 0.63 [95%CI: 0.53-0.75]; P < 0.001). Grade ≥3 adverse events occurred in 178 patients (29.7%, P < 0.001). Safety and efficacy of microwave ablation for Child B early stage hepatocellular carcinoma

Nobuhito Taniki1, Ryosuke Kasuga1, Yukiie Nakada1, Mayuko Kondo1, Takaya Tabuchi1, Fumie Noguchi1, Po-Sung Chu1, Shingo Usui1, Nobuhiro Nakamoto1, Takanori Kanai1

1Keio University Tokyo Japan

Background: Since most of the subjects of clinical trials which verify feasibility of Microwave ablation (MWA) are hepatocellular carcinoma (HCC) patients who have preserved liver function, the influence regarding the impact of impaired hepatic reserve on treatment outcomes has not been well established.

Methods: This retrospective cohort study enrolled 624 microwave ablation treatments using Enpiate ablation system (Covidien) during 2017 to 2022. Of those, 582 treatments were operated under the tumor settings of HCC with 3 or less lesions of 30 mm in diameter or single lesions of 50 mm. We compared patient background factors and treatment outcomes of 474 patients with Child A and 108 patients with Child B.

Results: Of the entire cohort, there were significant increase in the number of tumors and the maximum tumor diameter in Child B cases. However, 582 subjects finally enrolled in the analysis under the limited tumor settings, these factors were comparable in both groups. Not only factors related to hepatic reserve, platelet count and liver stiffness showed significant difference in each group. All of the outcomes showed worse result in Child B cases included severe complication rate (Child A 5/484 1.1% vs Child B 4/108 3.7%, p=0.0441), recurrence-free survival, and incidence of bile duct dilatation. Furthermore, ascites was extracted as a risk factor contributing to bile duct dilatation.

Conclusion: Child B patients are at increased potential risk which may contribute to poor treatment outcomes. Aside from considering liver transplantation, taking proactive preoperative measures is needed for effective and safe MWA procedure.
noninferior to sorafenib (Abou-Alfa et al. NEJM Evid 2022). Here, we report an updated 4-year OS analysis of HIMALAYA.

Methods: Participants with uHCC and no previous systemic treatment were randomized to STRIDE, durvalumab or sorafenib. Data cut-off was 23 January 2023. OS and serious treatment-related adverse events (TRAEs) were assessed. Baseline demographics and disease characteristics were assessed in long-term survivors (LTS; participants surviving ≥36 months beyond randomization).

Results: Follow-up duration was approximately 4 years across treatment arms (Table). The OS HR versus sorafenib (0.78; 95% CI, 0.67-0.92) and estimated 36-month OS rate (30.7%) for STRIDE were consistent with the primary analysis. The 48-month OS rate remained higher for STRIDE (25.2%) versus sorafenib (15.1%). No new serious TRAEs occurred after the primary analysis for STRIDE (17.5%). Durvalumab OS noninferiority to sorafenib and safety was consistent with the primary analysis. Baseline demographics, clinical characteristics and subsequent therapies, including tremelimumab rechallenge, for LTS in the STRIDE arm were generally consistent with the full analysis set, suggesting that LTS were not from any particular subgroup.

Conclusions: These data reinforce the sustained, long-term OS benefit of STRIDE versus sorafenib, demonstrating unprecedented 3- and 4-year OS rates and longest follow-up to date in phase 3 uHCC studies. STRIDE maintained a tolerable safety profile, with no new serious safety events.

Clinical Trial identification: NCT03298451

Temporal patterns of immune-mediated adverse events in HIMALAYA study in unresectable HCC

George Lau1, Bruno Sangro2, Oxana V. Crystler3, Wattana Sukdeeprasarnjaroen4, Oleg Lipatov5, Manabu Morimoto6, Isabelle Archambeaud7, Valentina Burgio8, Mallory Makowsky9, Alejandra Negro9, Ghassan K. Abou-Alfa10

1Humanity and Health Clinical Trial Center, Humanity and Health Medical Group Hong Kong Hong Kong, 2Liver Unit and HPB Oncology Area, Clinica Universidad de Navarra and CIBEREHDFundación Jiménez Díaz, Madrid, Spain, 3Department of Gastroenterology and Hepatology, Kindai University Faculty of Medicine Osaka Japan, 4Helen Diller Family Comprehensive Cancer Center, University of California San Francisco USA, 5Department of Internal Medicine, School of Medicine, Kyungpook National University Daegu Republic of Korea, 6Department of Oncology Area, Clínica Universidad de Navarra and CIBERERD Pamplona Spain, 7Department of Gastroenterology and Hepatology, Kindai University Faculty of Medicine Osaka Japan, 8Hepato-Gastro-Entérologie et Assistance Nutritionnelle, Institut des Maladies de l’Appareil Digestif (IMAD), Nantes Université Nantes France, 9Department of Medical Oncology, San Raffaele Scientific Institute Milan Italy, 10AstraZeneca Gaithersburg USA

Background: In the Phase 3 HIMALAYA study (NCT03298451) in uHCC, STRIDE (Single Tremelimumab Regular Interval Durvalumab) significantly improved overall survival versus sorafenib with manageable safety (Abou-Alfa et al. NEJM Evid 2022). In this exploratory analysis, we assessed temporal patterns of imAEs with STRIDE.

Methods: Safety was assessed in participants who received ≥2 dose of STRIDE or sorafenib. imAEs were AEs of special interest associated with drug exposure and consistent with an immune-mediated mechanism of action with no found alternate etiology.

Results: Safety was assessed in 388 (STRIDE) and 374 (sorafenib) participants. Median (range) duration of exposure was 5.5 (0.4-4.9) months for STRIDE (durvalumab exposure) and 4.1 (0.1-38.6) months for sorafenib. Any grade treatment-related AEs (TRAEs) and Grade 3/4 TRAEs were less frequent for STRIDE (75.8% and 25.8%, respectively) versus sorafenib (84.8% and 36.9%, respectively). Any grade imAEs and max Grade 3/4 imAEs occurred in 35.8% and 12.6% of participants, respectively. For STRIDE, imAEs with STRIDE occurred at time points assessed and did not most likely to occur within the first three months (Table). For STRIDE, any grade imAEs of gastrointestinal disorders and skin and subcutaneous tissue disorders were most common within the first month after treatment; any grade imAEs of endocrine disorders were most common between >1 and ≤2 months.

Conclusions: AEs with STRIDE were manageable and generally low grade. Although imAEs with STRIDE could occur at any time, most were observed within the first three months after treatment. Findings continue to support STRIDE for treatment of uHCC.
Abstract Submission No. 100070

Impact of NAFLD on the efficacy of immunotherapy for CHB-related Hepatocellular carcinoma

Jiaxin Han1, Wentao Kuai1, Ningning Zhang1, Wei Lu2, Liang Xu3
1Clinical School of the Second People’s Hospital, Tianjin Medical University Tianjin China, 2Department of Hepatobiliary Oncology, Liver Cancer Center, Tianjin Medical University Cancer Institute and Hospital, National Clinical Research Center for Cancer, Key Laboratory of Cancer Prevention and Therapy, Tianjin’s Clinical Research Center for Cancer, 3Tianjin Institute of Hepatology, Tianjin Second People’s Hospital Tianjin China

Objective: To investigate the impact of non-alcoholic fatty liver disease (NAFLD) on immune checkpoint inhibitors (ICIs) in patients with chronic hepatitis B (CHB)-related hepatocellular carcinoma (HCC).

Method: A total of 94 patients with chronic hepatitis B virus (HBV) infection-related HCC who received immunotherapy in Department of Hepatobiliary Oncology, Tianjin Second People’s Hospital and Tianjin Medical University Cancer Institute and Hospital from April 2021 to October 2022 were included in this study. According to the presence or absence of NAFLD, the patients were divided into concurrent NAFLD and CHB (NAFLD-CHB) group and the CHB group. SPSS 26.0 statistical software was used to analyze the demographic, laboratory, and tumor-related baseline data, and evaluate the efficacy and immune status of the two group patients.

Result: There was no significant difference in CR, SD, PR, ORR, and DCR between the two groups (all P > 0.05). Median progression-free survival (mPFS) in NAFLD-CHB group was significantly lower than that in CHB group (NAFLD-CHB group 11.6 months; P < 0.05). CD19+B cells (CHB group 9.79% vs NAFLD-CHB group 12.53%; P < 0.05) and CD3+CD4+CD8+T cells (CHB group 26.17% vs NAFLD-CHB group 16.07%; P < 0.05) in blood samples of NAFLD-CHB group were significantly lower than those of CHB group (P < 0.05). The percentages of CD4+PD1+T cells (CHB group 8.89% vs NAFLD-CHB group 17.56%; P < 0.05) and CD8+PD1+T cells (CHB group 7.42% vs NAFLD-CHB group 10.50%; P < 0.05) in the blood samples of NAFLD-CHB group were significantly higher than those of CHB-related HCC patients.

Conclusion: Concurrent NAFLD seems induce poorer efficacy and shorter progression-free survival when compared with CHB-related HCC patients, and this also might be attributed to the decrease of CD19+B cells, CD3+CD4+CD8+T cells and the increase of percentages of CD4+PD1+T cells and CD8+PD1+T cells.

Abstract Submission No. 100091

An Online Risk Stratification Model for Predicting Survival Duration of Older Patients with HCC

Xiaoxin Wu1, Juntao Tan2, Jingjing Chen3
1The First Affiliated Hospital, Zhejiang University School of Medicine Hangzhou China, 2Affiliated Banan Hospital of Chongqing Medical University Chongqing China, 3Zhejiang University City College Hangzhou China

Background: The objective of this study is to identify the prognostic factors of older patients with HCC and to construct a new prognostic model for predicting their overall survival.

Methods: 2,721 HCC patients aged ≥ 65 were extracted from SEER. 101 patients were from the Hospital.

Results: We found that the nomogram provided a good assessment of OS at 1, 3, and 5 years in older patients with HCC (1-year OS: (training set: AUC = 0.823 (95%CI: 0.803-0.845); internal validation set: AUC = 0.847 (95%CI: 0.818-0.876); external validation set: AUC = 0.732 (95%CI: 0.521-0.943)); 3-year OS: (training set: AUC = 0.813 (95%CI: 0.790-0.837); internal validation set: AUC = 0.844 (95%CI: 0.810-0.876); external validation set: AUC = 0.780 (95%CI: 0.674-0.887)); 5-year OS: (training set: AUC = 0.839 (95%CI: 0.806-0.872); internal validation set: AUC = 0.800 (95%CI: 0.751-0.849); external validation set: AUC = 0.821 (95%CI: 0.727-0.914)). The calibration curves showed that the nomogram was with strong calibration. The DCA indicated that the nomogram can be used as an effective tool in clinical practice. The risk stratification of all subgroups was statistically significant (P < 0.05). In the stratification analysis of surgery, Larger Resection (LR) achieved a better survival curve than Local Destruction (LD), but a worse one than Segmental Resection (SR) and Liver Transplantation (LT) (P < 0.0001). With the consideration of the friendship to clinicians, we further developed an online interface (OHCPredictor) for such a predictive function (https://juntaotan.shinyapps.io/dynnomapp_hcc/).

Conclusion: The online web interface of the predictive model provide easily-obtained access for clinicians.
**DISCUSSION**: The Weibull distribution closely approximated observed values. The time post-DAA treatment required for rates to drop to 1% aligns with clinical experiences.

**Conclusion**: Post-HCV treatment, the theoretical HCC onset and recurrence risk persist long-term.

**New FP therapy for long-term prognosis in patients with advanced hepatocellular carcinoma**

Hiroaki Nagamatsu1, Takeshi Watanabe1, Hiroto Ota1, Maki Toba1, Hitoshi Maruyama1

1Juntendo University Hospital Bunkyo-ku, Tokyo Japan

**Introduction**: In Japan, hepatic arterial infusion chemotherapy (HAIC) is recommended as an optional treatment in the 2021 guidelines. In 2021, New FP therapy (NFP) was reported to have a longer prognostic effect than sorafenib in advanced hepatocellular carcinoma with intrahepatic lesions.

**Objectives**: We will show the performance of NFP in this study at our hospital.

**Subjects**: We perform 2 courses using the temporary indwelling catheter system via the left brachial artery, and then we remove the temporary reservoir during hospitalization. We repeat this treatment 3 to 5 times with an interval of about 2 months. We aim for cancer-free by performing conversion therapy when PR or CR is obtained by NFP.

**Results**: There is almost no deterioration liver function. A total of 200 patients (69%) responded to NFP therapy, of which 80 patients achieved cancer-free outcome. 32 patients became cancer-free outcome with only NFP. We were able to add hepatic resection to 33 patients. Median OS (MST) after HAIC in all patients was 18 months. MST in patients who responded was 29 months, and in patients who achieved cancer-free outcome, it was extended to 67 months. The 5-year survival rate of all patients was 22%, and 67% for patients who got cancer-free outcome.

**Conclusions**: NFP has a high response rate and contributes to improve or maintain liver function by controlling PVTT. In response cases, long-term survival can be obtained by adding conversion therapy.

**Monocyte to High Density Lipoprotein-Cholesterol Ratio Predicts Prognosis of MAFLD-related HCC**

Tongguo Miao1, Xianze Lou1, Shiming Dong1, Xiaoxiao Zhang1, Weimei Guan1, Ying Zhang1, Lu Li1, Xiwei Yuan1, Dong Ma2, Yueming Nan1

1Department of Traditional and Western Medical Hepatology, Hebei Medical University Third Hospital & Hebei International Joint Research Center for Liver Cancer Molecular Diagnosis, Hebei Medical Science and Technology Cooperation Base Shijiazhuang Ch, 2Department of Biochemistry and Molecular Biology, Key Laboratory of Neural and Vascular Biology, Ministry of Education, Hebei Medical University Shijiazhuang China

**Background**: The incidence of non-B and non-C hepatocellular carcinoma (NBNC-HCC) is increasing globally. Metabolically associated fatty liver disease (MAFLD) has been a contributing factor to this rising trend in NBNC-HCC incidence. The monocyte-to-high-density lipoprotein-cholesterol ratio (MHR) is a new prognostic marker that connects systemic inflammation with disorders of lipid metabolism. Therefore, MHR may be a potential prognostic predictor of patients with MAFLD-related HCC (MAFLD-HCC).

**Patients and methods**: This retrospective study of patients with MAFLD-HCC included training (n=112) and internal validation (n=37) cohorts. Univariate and multivariate Cox proportional hazard regression analysis was conducted to identify independent risk factors of survival. A visual nomogram was constructed to assess the performance of the two groups. Furthermore, receiver operating characteristic (ROC) curves and calibration curves were used to verify the prognostic discriminative ability of this nomogram, even in the MHR, ALBI grade, and MHR-ALBI model.

**Results**: Univariate and multivariate analyses revealed that extrahepatic metastases, Vascular invasion, Barcelona staging B, C, D, elevated ALBI Grade 3, C-reactive protein (CRP), and MHR were independent risk factors for the prognosis of MAFLD-HCC. Moreover, calibration plots showed good discrimination and consistency when the significant factors were entered into the nomogram. Meanwhile, the MHR strongly correlated with the prognosis of cancer under a background of MAFLD-HCC, with a sensitivity of 88.89% and a specificity of 79.61%.

**Conclusion**: The novel nomogram demonstrated good value in predicting the overall survival of patients with MAFLD-HCC. The MHR may be a potential predictor of prognosis.

**Comparison of atezolizumab plus bevacizumab and lenvatinib for hepatocellular carcinoma with PVTT**

JEAYEON PARK1, YUN BIN LEE1, HYUNJAE SHIN1, YOONGSU PARK1, MOON HAENG HUR2, MIN KYUNG PARK1, DAE-WON LEE2, EUN JU CHO1, KYUNG-HUN LEE2, JEONG-HOON LEE1, SU JONG YU1, TAE-YONG KIM1, YOON JUN KIM1, TAE-YOU KIM2, JUNG-HWAN YOON1

1Department of Internal Medicine and Liver Research Institute, Seoul National University Hospital, Seoul National University College of Medicine Seoul South Korea, 2Cancer Research Institute, Seoul National University Hospital, Seoul National University College of Medicine Seoul South Korea

**Background/Aim**: Atezolizumab plus bevacizumab and lenvatinib are currently available as first-line therapy for the treatment of unresectable hepatocellular carcinoma (HCC); however, comparative efficacy studies are still scarce. This study aimed to investigate the effectiveness of these treatments in HCC patients with portal vein tumor thrombosis (PVTT).

**Methods**: We retrospectively included patients who received either atezolizumab plus bevacizumab or lenvatinib as first-line systemic therapy for HCC with PVTT. Primary endpoint was overall survival (OS), and secondary endpoints included progression-free survival (PFS) and disease control rate (DCR) determined by Response Evaluation Criteria in Solid Tumors, version 1.1.

**Results**: A total of 52 patients were included: 30 received atezolizumab plus bevacizumab and 22 received lenvatinib. The median follow-up duration was 6.4 months (interquartile range, 3.9-9.8). The median OS was 10.8 months (95% confidence interval [CI], 5.7-9.8) with lenvatinib (P=0.26 by log-rank test). There was no statistically significant difference in OS (adjusted hazard ratio [aHR], 0.71; 95% CI, 0.34-1.49; P=0.37). The median PFS was similar (P=0.63 by log-rank test), with 4.1 months (95% CI, 3.3-7.7) for
atezolizumab plus bevacizumab and 4.3 months (95% CI, 2.6-5.8) for lenvatinib (aHR, 0.93; 95% CI, 0.51-1.69; P=0.80), HRs were similar after inverse probability treatment weighting. The DCRs were 23.3% and 18.2% in patients receiving atezolizumab plus bevacizumab and lenvatinib, respectively (P=0.74).

**Conclusion:** The effectiveness of atezolizumab plus bevacizumab and lenvatinib was comparable for the treatment of HCC with PVTT.

**Efficacy and safety of multitherapy for Locally Advanced, Unresectable Hepatocellular Carcinoma**

ShiZhong Yang1, HaiXin Yin1, Bin Shu1, Lin Zhang1, Ying Liu1, Xiaowei Yang1, Guangxin Li1, Xiaojuan Wang1, Gong Li1, Yuwei Zhang1, Jiahong Dong1

1Hepato-pancreato-biliary Center, Beijing Tsinghua Chang Gung Hospital, Beijing, Beijing China

**Background:** Recently, lenvatinib plus PD-1 inhibitors combined with or without hepatic arterial infusion chemotherapy (HAIC) has shown promising survival benefits for advanced hepatocellular carcinoma (HCC). This study aimed to explore the safety and efficacy of multitherapy versus transarterial chemoembolization (TACE) for locally advanced HCC patients.

**Methods:** Clinical data for initially unresectable HCC with PVTT from January 2018 to January 2023 in Tsinghua Changgung Hospital were collected. Conversion therapy, objective response rate (ORR, mRECIST), overall survival (OS), and adverse reactions were analyzed.

**Results:** 51 HCC patients with PVTT were enrolled, 32 (62.7%) receiving combination therapy (Vp2/Vp3/Vp4:20/8, Japanese Typing) and 19 (37.3%) receiving TACE (Vp2/Vp3/Vp4:11/7). In the combined group, the median overall survival (mOS) was not reached, the one-year OS rate was 90.1%, in the TACE group, the mOS was 14 months (95% CI, 10.0-18.0) and the one-year OS rate was 59.7%. OS in the combined group was longer than that in the TACE group (HR 0.23; 95% CI, 0.09-0.59 ; p=0.0021). In combined group, ORR was 50%, 10 (31.2%) patients achieved remission, 3 (30%) patients reached pathological complete response (pCR), and 3 (30%) reached major pathological remission (MPR); in TACE group, ORR was 26.3%, 3 (15.8%) patients achieved remission, and 1 (5.3%) patient reached MPR. There was no significant difference in adverse events in the two groups.

**Conclusions:** For patients with initially unresectable HCC with PVTT, local therapy in combination with systematic treatment have more prolonged survival and a relatively high surgical conversion rate in carefully selected patients with ECOG 0-1.

**Experience of tremelimumab plus durvalumab in patients with unresectable hepatocellular carcinoma**

Michiko Yamada1, Kaoru Tsuchiya1, Yutaka Yasaki1, Yuki Tanaka1, Haruka Miyamoto1, Taisei Keitoku1, Risa Okada1, Mayu Higuchi1, Kenta Takaura1, Shohei Tanaka1, Chiaki Maeyashiki1, Nobuharu Tamaki1, Hiroyuki Nakanishi1, Masayuki Kurosaki1, Namiki Izumi1

1Musashino Red Cross Hospital Musashino Japan

**Background:** Tremelimumab plus durvalumab (Tre+Dur) is the first combination therapy of anti-CTLA-4 and anti-PD-L1 antibodies approved for unresectable hepatocellular carcinoma (u-HCC) in Japan and has been used since March 2023. We investigated the clinical outcomes of the therapy in real-world practice.

**Methods:** Patients who received Tre+Dur at our hospital from April 2023 were analyzed retrospectively. Imaging evaluations were performed using RECIST v1.1 with MDCT every 6-8 weeks after the administration of Tre+Dur. Adverse events were evaluated based on CTCAE v5.0.

**Result:** Between April and September 2023, 22 patients were treated with Tre+Dur. Eight patients were without viral infection. The treatment line was 1st (n=2), 2nd (n=4), 3rd (n=4), 4th or later (n=12). BCLC stage was B (n=5) and C (n=17). The median ALBI score was 2.09 and 13 patients were ALBI grade 2b. The objective response rate was 22.2% and disease control rate was 66.7% within the 3rd -line, and 10.0% and 30.0% in the 4th -line or later patients. Tre+Dur has been continued in 5 patients (23%) and post-treatments were introduced in 10 patients. 7 patients were converted to BSC. Grade 3 immune-mediated adverse events (imAE) were observed within 4 weeks in 8 patients, including colitis (n=5), adrenal insufficiency (n=2), and renal failure (n=1). All 5 patients with colitis required steroid therapy, and 3 patients had a poor response to steroids. These 3 patients recovered after the administration of infliximab.

**Conclusion:** In Tre+Dur therapy, the radiological response of patients who received 1st- to 3rd-line treatment was comparable to that in the phase 3 study.

**O-0628**

**Lung metastasis from HCC is more powerful in predicting brain metastasis rather than bone metastasis**

Yasunori Minami1, Tomoko Aoki1, Masahiro Morita1, Hirokazu Chishina1, Masahiro Takita1, Satoru Hagiwara1, Hiroshi Ida1, Kazuomi Ueshima1, Naoshi Nishida1, Masatoshi Kudo1

1Kindai University Faculty of Medicine Osaka-sayama Japan

**Purpose:** Brain metastases from hepatocellular carcinoma (HCC) are relatively rare. However, the incidence of brain metastases seems to have increased in recent years. The aim of this study was to characterize the incidence proportion and survival of newly diagnosed HCC with brain metastases.

**Materials and Methods:** Between January 2009 and December 2020, 942 advanced HCC patients with either metastatic or locally advanced disease untreatable by locoregional therapies were enrolled in clinical trials of first-line systemic chemotherapies in Kindai University Hospital. Total 276 HCC patients who developed extrapleural metastases were retrospectively enrolled in this study, and the clinicopathologic features and survival times of those were analyzed.

**Results:** The median age at diagnosis of extrapleural metastases was 71.0 years. 222 patients were male, and 54 patients were female. 48 patients were infected with hepatitis B virus (HBV), 120 patients were infected with hepatitis C virus (HCV), and 108 patients were not infected with HBV or HCV. Thirteen patients (4.7%) were found to have brain metastasis. The median interval from the diagnosis of HCC to brain metastases was 56.9 months. Extrapleural metastases and chronic kidney disease were brain metastasis risk factors for HCC patients. Lung metastasis was the strongest risk factor for brain metastasis (p<0.001) rather than of bone metastasis (p=0.051).

**Conclusions:** The patients having brain metastases from HCC had poor prognosis.
This study can guide patients with high-risk brain metastases from HCC to undergo diagnostic brain imaging tests, early diagnosis, and treatment to prolong the survival of patients.

Abstract Submission No. 100112

Fatal ARDS after a single dose of ATZ/BV for HCC, autopsy findings: a case report

Yasunori Minami1, Masahiro Morita1, Hirokazu Chishina1, Tomoko Aoki1, Takuya Matsubara1, Masahiro Takita1, Kazuhiko Kuwahara1, Satoru Hagiwara1, Hiroshi Ida1, Kazuomi Ueshima1, Naoshi Nishida1, Akihiko Ito1, Masatoshi Kudo1
1Kindai University Faculty of Medicine Osaka-sayama Japan

The combination of atezolizumab (PD-L1 inhibitor) and bevacizumab (VEGF inhibitor) has been used to unrespective hepatocellular carcinoma (HCC) as first-line therapy. Various adverse events are associated with these therapies, including hepatitis, endocrine disorders, nephritis, dermatitis, and interstitial lung disease. It is believed these adverse events occur in part due to their additive effects on tumor growth and their reprogramming of the immunosuppressive microenvironment into an immunostimulatory microenvironment. These events usually occur after several months and rounds of treatment. Here we present a case of a 63-year-old male with HCC who experienced acute respiratory distress syndrome (ARDS) after only a single dose of combination therapy with atezolizumab and bevacizumab. He presented with high grade of dyspnea and bilateral lung consolidation; twelve days after admission he died. Histologic examination revealed that immune-mediated inflammation destroyed the alveolar capillary barrier (alveolar epithelium and endothelium), increased its permeability and caused intra-alveolar hemorrhage and edema. PD-L1 staining was positive in the lung interstitium, suggesting that antibody-mediated injury played a significant role in the pathogenesis of ARDS. Additional studies ruled out an infectious etiology. Immune checkpoint inhibitors are increasingly more common, and it is important clinicians are aware patients can present with ARDS early in the course of treatment.

Abstract Submission No. 100390

A Predictive Model to assess Recent Recurrence after Hepatectomy for Hepatocellular Carcinoma

Hong Peng1, Siyi Lei1, Tingting Xiong1, Qing Zhang1, Tianzhao Liu1, Li Long1, Yi Zhang1, Gen Chen1, Wei Fan1, Jinhui Xu1, Xinhua Luo1
1Guizhou Provincial People’s Hospital Guiyang, Guizhou China

Background and Aims: We still lack effective prediction models for recent recurrence (time to recurrence [TTR] < 2 years) after hepatectomy for hepatocellular carcinoma (HCC). This study focuses on the factors including sarcopenia which maybe related to recent recurrence of postoperative HCC patients, and attempt to fit an interventional prediction model.

Methods: We retrospectively analyzed 283 hepatitis B-related HCC patients who underwent curative hepatectomy for the first time and measured the preoperative skeletal muscle index (SMI). Cox multivariate analysis was performed to identify the risk factors of postoperative recurrence. A nomogram model was developed to predict the survival of HCC patients, and its predictive performance was validated.

Results: Multivariate analysis showed that sarcopenia, alpha-fetoprotein (AFP) ≥ 40ng/ml, the maximum diameter of tumor > 5cm, and hepatitis B virus [HBV] DNA level ≥ 2000IU/mL were independent risk factors associated with postoperative recurrence of HCC. The SAMD model predicting the recurrence-free survival (RFS) of HCC patients was established based on the above factors. The area under the curve(AUC) of the SAMD model was 0.782 (95% CI: 0.705 - 0.858) in the training cohort (sensitivity 81%, specificity 63%) and 0.773 (95%CI: 0.707 - 0.838) in the validation cohort. Besides, a SAMD score ≥ 110 was better to distinguish the high-risk group of postoperative recurrence of HCC.

Conclusion: Sarcopenia is associated with recent recurrence after hepatectomy for HCC. A nutritional status-based prediction model is first established for postoperative recurrence of HCC, which is superior to other models and contributes to prognosis prediction.

Background: Chronic liver diseases are associated with poor nutritional status especially when progress to advanced liver disease or liver cirrhosis, and such status is related to development of hepatocellular carcinoma (HCC). Sarcopenia may reflect nutritional status. Transarterial chemoembolization (TACE) is a standard of care for intermediate-stage HCC, although treatment response varies. Whether sarcopenia affect prognosis of TACE remains unclear.

Methods: We recruited 161 adult HCC patients who were TACE-naive from 2015 to 2018. Skeletal muscle index (SMI), a height squared-adjusted cross-section area of the muscles at the third lumbar vertebra on CT or MRI, is an indicator of sarcopenia.

Results: Among these 161 patients, 118 were male and 43 were female. The average age was 67 years old. 32 male patients (27.1%) had sarcopenia and 23 female patients had sarcopenia (53.5%). 156 patients (96.9%) had liver cirrhosis. 41 patients (25.5%) had infiltrative type HCC. The average tumor number was 5.4. After TACE, 15 patients had progressive disease (PD), 38 patients had complete remission (CR), 89 patients had partial response (PR), and 15 patients had stable disease (SD).

In univariate Cox regression analysis, infiltrative type, vascular invasion, necrosis, tumor number, largest tumor size, and post-TACE AFP had impact on OS (overall survival), while in multivariate Cox regression analysis, vascular invasion, ECOG-PS, pre-TACE ALT, and post-
TACE platelet count had impact on OS. Sarcopenia had no impact in both univariate and multivariate Cox regression analysis. 

**Conclusions:** Our data suggest that sarcopenia has no impact on the prognosis of TACE for intermediate-stage HCC.

**Time-to-interventional failure in hepatocellular carcinoma**

Yoshinori Takeda1, Hiroshi Imamura1, Akio Saiura1

1Department of Hepatobiliary and Pancreatic Surgery, Juntendo University Tokyo Japan

**Background:** Several curative-intent treatments are often applicable depending on the recurrence pattern in patients with hepatocellular carcinoma (HCC) undergoing hepatectomy; therefore, recurrence-free survival (RFS) is not considered an appropriate surrogate for overall survival (OS) in HCC. We assessed whether the time interval between the initial hepatectomy and the emergence of recurrence not indicated for curative-intent treatments, defined as time-to-interventional failure (TIF), is a better indicator of OS in patients with HCC undergoing hepatectomy.

**Methods:** We retrospectively reviewed patients who underwent initial curative hepatectomy for HCC in our hospital between 2009 and 2018. Recurrence not indicated for curative-intent treatments were defined as multinodular (≥4) intrahepatic recurrence, macroscopic vascular invasion, and/or extrahepatic lesions. We compared the correlation between RFS and TIF with OS and investigated the similarities of prognostic factors among RFS, TIF, and OS.

**Results:** In total, 266 patients were included. With a median follow-up of 56 months, 146 patients experienced any type of recurrence, and 103 patients experienced recurrences not indicated for curative-intent treatments. The median OS, RFS, and TIF were 59, 25, and 45 months, respectively. TIF had a stronger correlation with OS than with RFS ($r^2 = 0.808$ vs. 0.476). Multivariate analysis revealed that macroscopic vascular invasion, poor grade of tumor differentiation, and F3 or 4 were independent prognostic factors to TIF and OS, while macroscopic vascular invasion, maximum tumor size >5 cm, and R1 resection were factors to RFS.

**Conclusions:** TIF was a more appropriate surrogate for OS than for RFS in patients with HCC.

**Usefulness of a novel microcatheter insertable port ReMAP/System-i for novel transarterial therapy of HCC**

Hideki Iwamoto1,2, Satoshi Itano3, Takashi Nizeki3, Tomotake Shirono1, Takumi Kagawuchi3

1Kurume University School of Medicine Kurume Japan, 2Iwamoto Internal Medicine Clinic Fukuoka Japan, 3Kurume Central Hospital Kurume Japan

**Purpose:** Transarterial therapy (TAT) for HCC plays an important role in the treatment of HCC. However, the invasiveness and difficulty of the TAT procedures should be improved. Recently, a novel microcatheter insertable port for intermittent TAT “ReMAP/System-i” was developed in Japan. In the study, we assessed the feasibility and safety of ReMAP/System-i.

**Methods:** In the placement of ReMAP, a side-holed indwelling catheter (Anthron PU catheter, TORAY Medical Co., Ltd) was inserted into the femoral artery, and the catheter tip was placed in the descending aorta, and the catheter tip was placed in the descending aorta. ReMAP was connected to the tail of the catheter and subcutaneously implanted into the femoral region. A high-flow microcatheter can be inserted into ReMAP and inserted into the targeted artery for treatment. Using this system, transarterial arterial chemoeMBOLization (TACE) and HAIC can be repeatedly performed. The feasibility and safety of ReMAP/System-i were assessed in the study.

**Results:** ReMAP/System-i was implanted in 58 patients. The most frequent reason chosen ReMAP/System-i was “need of TAT for several tumor-feeding arteries (48%)”. The median procedure time for ReMAP implantation was 42 min (25-94). Among 58 patients, 6 cases had a complication regarding the procedure (3 wound dehiscence, 3 wound infection). By using ReMAP/System-i, repeated TATs have been performed from not only the hepatic arteries but also other tumor-feeding arteries, repeatedly.

**Conclusions:** ReMAP/System-i is a promising device, which allows us to perform repeated TATs for any arteries with less invasiveness.

**Association between SGLT-2 inhibitors and death from hepato-bilio-pancreatic cancer**

Ka Shing Cheung1, 2, Xianhua Mao1, 2, Jing-Tong Tan1, Ho Ming Cheng1, Man-Fung Yuen4, Wai-Kay Seto1, 2, 3

1Department of Medicine, School of Clinical Medicine, The University of Hong Kong Hong Kong, 2Department of Medicine, The University of Hong Kong-Shenzhen Hospital Shenzhen China, 3State Key Laboratory of Liver Research, The University of Hong Kong Hong Kong

**Background:** Association of sodium-glucose cotransporter-2 inhibitors (SGLT-2i) with all-cause and hepato-bilio-pancreatic cancer-related mortality remains unknown in patients with diabetes mellitus (DM).

**Methods:** Data of adult patients with newly diagnosed DM (hemoglobin A1c ≥6.5% or fasting plasma glucose of ≥7mmol/L) were retrieved from a territory-wide healthcare database in Hong Kong between 2010 and 2022. Primary outcomes were mortality from cancer of liver, bile duct, gallbladder and pancreas. Secondary outcome was all-cause mortality. Primary exposure was SGLT-2i use (including canagliflozin, dapagliflozin, empagliflozin, and ertugliflozin), which was treated as time-varying variable to address immortal time bias. Patients were followed from index date (DM diagnosis) till death or study end date (December 2022). Multivariable Cox model was used to calculate adjusted hazard ratios (HRS) of outcomes with SGLT-2i use by adjusting for 25 covariates including age, sex, DM complications, comorbidities, and concomitant use of medications (Table 1).

**Results:** Of 324,111 eligible subjects (mean age:59.6+/−11.3) years; male:181,480 [53.0%]; median follow-up: 7.0 years [IQR:4.7-9.9], 32,684 (9.6%) were SGLT-2i users (Table 1). There were 22,547 (6.6%) all-cause deaths (liver cancer:901; gallbladder cancer:76; bile duct cancer:243; pancreatic cancer:710). The aHR of death from liver, bile duct, gallbladder and pancreatic cancer was 0.39 (95% CI:0.21-0.70), 0.45 (95% CI:0.25-0.81), 0.74 (95% CI:0.10-5.43) and 1.03 (95% CI:0.64-1.66), respectively. SGLT-2i use also associated with lower risk of all-cause mortality (aHR:0.52;95% CI:0.47-0.59).

**Conclusion:** SGLT-2i use associated with lower risk of all-cause mortality including death from liver and bile duct cancer. This provides additional insight into the choice of anti-diabetic drugs in clinical practice.

Differences in hemodynamics of lenvatinib based on liver function for hepatocellular carcinoma

Kazufumi Kobayashi¹, Sadahisa Ogasawara¹, Tomomi Okubo², Michihisa Moriguchi³, Kazuyoshi Nakamura⁴, Ryosaku Azemoto⁵, Kenji Ito⁶, Shinichiro Okabe⁷, Masanori Atsukawa⁸, Ei Itoyabashi⁹, Masafumi Ikeda⁹, Naoki Morimoto¹⁰, Yoshito Itoh¹¹, Naoya Kato¹²

¹Department of Gastroenterology, Graduate School of Medicine, Chiba University Chiba Japan, ²Division of Gastroenterology, Department of Internal Medicine, Nippon Medical School Chiba Hokusoh Hospital Chiba Japan, ³Department of Gastroenterology and Hepatology, Kyoto Prefectural University of Medicine Kyoto Japan, ⁴Department of Gastroenterology, Chiba Cancer Center Chiba Japan, ⁵Department of Gastroenterology, Kimitsu Chuo Hospital Chiba Japan, ⁶Department of Gastroenterology, National Hospital Organization Chiba Medical Center Chiba Japan, ⁷Department of Gastroenterology, Matsudo City General Hospital Chiba Japan, ⁸Department of Gastroenterology, Asahi General Hospital Chiba Japan, ⁹Department of Hepatobiliary and Pancreatic Oncology, National Cancer Center Hospital East Chiba Japan, ¹⁰Division of Gastroenterology, Department of Medicine, Jichi Medical University Tochigi Japan

Background: The aim of this study was to assess the safety and efficacy of lenvatinib in real-world practice, with a focus on plasma concentration analysis.

Methods: This multicenter, nonrandomized, open-label prospective study was conducted at 10 medical facilities in Japan (jRCTs031190017). Eligible patients had advanced hepatocellular carcinoma and were suitable for lenvatinib treatment. The study included patients with high tumor burden (with >50% intrahepatic tumor volume, main portal vein invasion, or bile duct invasion) and Child-Pugh B status. Plasma concentrations of lenvatinib were monitored on days 1 (multiple times), 8, and 15.

Results: From December 2019 to September 2021, a total of 59 patients were analyzed, with 47 classified as Child-Pugh A and 12 as Child-Pugh B. Patients with Child-Pugh B exhibited a higher frequency of grade 3 or higher adverse events (AEs) and a higher discontinuation rate compared to patients with Child-Pugh A. The median overall survival was 19.7 and 4.1 months in Child-Pugh A and B, respectively. Plasma concentrations were found to be higher in Child-Pugh B patients on days 8 and 15, and higher concentrations were correlated with dosage adjustments and reduced relative dose intensity (RDI).

Conclusions: Patients with inadequately maintained liver function may exhibit an inclination toward elevated plasma concentration of lenvatinib, potentially leading to a higher incidence of AEs and lower RDI.

A tertiary hospital experience of atezolizumab & bevacizumab for advanced hepatocellular carcinoma

Callista Vania Raharjo¹, Raji Joseph¹, Elizabeth Stratton¹, Miriam Levy², Emilia Prakoso³

¹Gastroenterology Department, Liverpool Hospital Sydney, NSW Australia, ²The University of New South Wales Sydney, NSW Australia, ³The University of Sydney Sydney, NSW Australia

Background: Hepatocellular carcinoma (HCC) contributes as the 7th most frequently diagnosed cancer, with approximately 80% of patients presenting with intermediate or advanced stage HCC. The combination of atezolizumab plus bevacizumab (A+B), have become first line treatment of advanced HCC not amenable to resection or locoregional therapy since 2020.

AIM: To characterise the cohort who received A+B at in Liverpool Hospital, Sydney, Australia and assess its efficacy and safety

METHODS: Patients who received Atezolizumab 1,200 mg plus bevacizumab 15 mg/kg intravenously every 3 weeks at Liverpool Hospital between October 2020 and March 2023 were identified from prospectively maintained HCC database.

Results: Table 1 summarises our patients’ demographics. Barcelona Clinic Liver Cancer (BCLC) stage of patients were C in 31 patients (63.3%) and B in 17 patients (34.7%). One patient (2.0%) with BCLC 0 was given A+B because of recurrent HCC following tumour resection. Table 2 summarises patient outcomes as of March 2023. Adverse events of any grade occurred in 29 patients (59.2%). The most common adverse events were fatigue (n=10, 20.4%) and diarrhoea (n=7, 14.3%). Grade 3-4 adverse events that occurred were diarrhoea (n=4, 8.2%), pyrexia (n=3, 6.1%), proteinuria (n=3, 6.1%), and gastrointestinal bleeding (n=2, 4.08%). The median overall survival was 14 months (95%CI, 12.4-20.3).

Conclusion: Treatment cessation was majority due to HCC progression. The rate of any adverse events was high, however significant side effects were uncommon. Longer follow-up duration and larger patient
Background: Atezolizumab plus bevacizumab combination therapy (ATZ/BV) is recommended for unresectable hepatocellular carcinoma (u-HCC) patients. The present study aimed to clarify whether tumor marker response can predict efficacy and prognosis in ATZ/BV.

Methods: A total of 73 patients with u-HCC who received ATZ/BV were included. The definition of early tumor response (ETR) and early disease control (EDC) was complete response (CR) + partial response (PR) + stable disease (SD) after 6 weeks, respectively. Early tumor marker response (ETMR) was defined as a reduction in tumor markers after 3 weeks.

Results: Initial therapeutic response was CR 0, PR 22 (30%), SD 24 (33%), PD 20 (27%), respectively. Although no significant difference was seen in overall survival between ETR and non-ETR groups, there was a significant difference between EDC and non-EDC groups (p<0.001). MST of EDC and non-EDC groups were 14.6 and 6.3 months, respectively. Independent pre- and post-treatment factors contributing to survival were performance status (PS), albumin-bilirubin score, lens culinaris-agglutinin-reactive fraction of alpha-fetoprotein (AFP-L3), and EDC. Independent pre- and post-treatment factors contributing to EDC was PS, prior tyrosine kinase inhibitor treatment, AFP-L3, and AFP- and des-gamma-carboxy prothrombin (DCP)-ETMR. The area under the receiver operating characteristic curve for predicting EDC with AFP-, AFP-L3-, and DCP-ETMR combination were 0.734, 0.621, and 0.682, respectively. Sensitivity, specificity, and accuracy of prediction for EDC using ETMR combination were 0.848, 0.700, and 0.803, respectively.

Conclusions: ETMR can predict disease control and prognosis of ATZ/BV for u-HCC.

mRNA based HBV-specific TCR T-Cell Infusions can Induce Broad HBV T-cell Response in HBV-related HCC

Thinesh Krishnamoorthy1, Wai-Meng David Tai2, Anthony Tanoto Tan3, Wei Qiang Leow3, Joe Yeong4, Regina Wanju Wang5, Liyun Lay6, Lu-En Wai6, Sarene Koh6, Antonio Bertoletti6, Tingting Wang6

1Department of Gastroenterology & Hepatology, Singapore General Hospital Singapore Singapore, 2Division of Medical Oncology, National Cancer Centre Singapore Singapore, 3Emerging Infectious Diseases, Duke-NUS Medical School Singapore Singapore, 4Department of Anatomical Pathology, Singapore General Hospital Singapore Singapore, 5Institute of Molecular and Cell Biology, A*STAR Singapore Singapore, 6Lion TCR Pte Ltd Singapore Singapore, 7Singapore Immunology Network, A*STAR Singapore Singapore

Background: LioCyx-M, autologous T-cells modified with mRNA encoding HBV-specific TCR, has shown promise in advanced and recurrent HCC patients. We report safety and biomarker findings from a phase 1b study (NCT04745403) post LioCyx-M infusions in primary HBV-related HCC patients not amenable to/failed conventional treatment.

Methods: A 71-year-old male, who failed two prior systemic treatments, received 8 LioCyx-M infusions at escalating doses (1×10^6, 1×10^6, 3×5×10^6 cells/kg) intravenously bi-weekly, without lymphodepletion. For pharmacodynamic and immunological biomarker analysis, a whole blood assay (WBA) detected LioCyx-M function in peripheral blood (response to single target HBV-peptides) and explored evidence of epitope spreading (response to other HBV-peptides). Plasma protein levels, assessed through Proximity Extension Analysis, an assay (PEA), elucidated systemic immune responses and their relationship with clinical symptoms.

Results: LioCyx-M infusions were well-tolerated, with manageable grade 1-2 fever and CRP elevation at highest doses (5×10^6 cells/kg). These infusions transiently elevated NLR (neutrophil/lymphocyte ratio), PLR (platelet/lymphocyte ratio) and reversible liver inflammation (ALT & AST), indicating on-target effects. A 2.62-fold reduction in serum IGF-1 level significantly predicted the progression and survival in HCC patients.

Methods: We conducted a comprehensive literature search (September-October 2023) from PubMed, EMBASE, and Cochrane databases with the search terms “Insulin-like Growth Factor 1” AND “Hepatocellular Carcinoma” that were published within the year of 2000 to 2023. We screened 184 records after checking duplicates between databases. We examined 48 full-text articles and excluded 35 articles as they did not meet the inclusion criteria. A total of 13 cohort studies with calculation of relative risk (RR) of serum IGF-1 for HCC time-to-progression (TTP) and overall survival (OS) were subjected to statistical analysis using STATA 17. We assessed the ability of serum IGF-1 to predict HCC progression and survival using random effect model to estimate pooled RR. Heterogeneity among studies was assessed by the Cochran’s Q and I^2 statistics. Publication bias was analysed using Begg funnel plot and Egger test.

Result: The meta-analysis of selected studies showed that low level serum IGF-1 significantly predicted shorter TTP (RR 2.36;95% CI 1.51-3.68) and poorer OS (RR 2.17;95% CI 1.72-2.74) in HCC patients, p value=0.00.

Conclusions: Serum IGF-1 level independently predicted the progression and survival in HCC patients. Further studies are needed for better causation explanation.
CEUS for Differentiation of Benign Vs Malignant PVT in HCC - A Systematic Review with Meta-analysis.

VANEET JEARTH1, Suprabhat Giri2, Arun Vaidya1, Dhiraj Agrawal4, Jijo Varghese3, Ranjan Kumar Patel6, Taraprasad Tripathy4, Ankita Singh1, Swati Das2

1Post Graduate Institute of Medical Education & Research Chandigarh India, 2Kalinga Institute of Medical Sciences Bhubaneswar India, 3Seth GS Medical College and KEM Hospital Mumbai India, 4PACE Hospital, Hyderabad, India Hyderabad India, 5KM Cherian Institute of Medical Sciences Kallissery India, 6All India Institute of Medical Sciences Bhubaneswar India

Background: Patients with cirrhosis and hepatocellular carcinoma (HCC) can develop both benign and malignant portal vein thrombosis (PVT). Characterizing the nature of PVT is important for planning an optimal therapeutic strategy. In the absence of typical findings or contraindications to CT or MRI, contrast-enhanced ultrasound (CEUS) could help in this differentiation. The present meta-analysis aimed to evaluate the performance of CEUS for characterizing PVT in patients with HCC.

Methods: Electronic databases of PubMed, Embase, and Scopus were searched from inception to 31st December 2022 for studies analyzing the role of CEUS in the differentiation of benign and malignant PVT in HCC. Using the bivariate random effect model, pooled sensitivity and specificity were calculated, and the summary receiver operating characteristic (sROC) curve was plotted. Result: A total of 12 studies with data from 712 patients were included in the meta-analysis. The pooled sensitivity and specificity of CEUS for the diagnosis of TIV were 97.0% (95% CI: 93.0 - 98.7) and 96.8% (95% CI: 92.1 - 98.7), respectively, without significant heterogeneity. A sROC curve was plotted, and the area under the receiver-operating characteristic was 0.99 (95% CI: 0.98 - 1.00). Despite the presence of publication bias, sensitivity analysis did not show any change in sensitivity and specificity.

Conclusion: CEUS is an effective diagnostic modality differentiation of benign and malignant PVT in patients with HCC and can be an alternative modality to CT or MRI. Further studies are required to study the role of CEUS as a first-line diagnostic modality for the characterization of PVT in HCC.

Nonselective β-blocker use does not impact on mortality in patients with hepatocellular carcinoma

Hin Yan Agnes Ho1, 2, Philip Lung-Wai Au-Doung3, Terry Cheuk-Fung Yip1, 2, 3, Mandy Sze-Man Lai2, 3, Vincent Wai-Sun Wong6, Grace Lai-Hung Wong6, 2, 3

1Department of Medicine and Therapeutics, The Chinese University of Hong Kong Hong Kong, 2Institution of Digestive Disease, The Chinese University of Hong Kong Hong Kong, 3Medical Data Analytics Centre (MDAC), The Chinese University of Hong Kong Hong Kong

Background: Hepatocellular carcinoma (HCC) contributes to a substantial burden of mortality across the globe. Increasing evidence supports the role of non-selective beta-blockers (NSBB) in reducing liver decompensation and prolonging survival in cirrhotic patients. However, the effect of NSBB on liver-related mortality in HCC patients remains unestablished.

Materials and methods: All patients with HCC and esophageal and/or gastric varices from January 2000 to December 2020 were identified from a territory-wide database in Hong Kong. Participants were
classified into three groups using a time-dependent covariate (i) propranolol users (ii) carvedilol users (iii) NSBB non-users. The primary endpoint was liver-related mortality in 5 years. Cause-specific hazard model was used for competing risk analysis. Liver transplantation and non-liver-related morality were considered as competing events.

Results: A total of 5,454 patients with 4,119 propranolol users, 86 carvedilol users, 1,249 non-users (mean age 60.4±11 years, male 82.0%) were included in the analysis. Most patients had viral cirrhosis (78.3%). The use of propranolol and carvedilol did not have a significant impact on liver-related mortality (adjusted cause-specific hazard ratio [aC-SHR] 1.03, 95% CI 0.97-1.12, p=0.42; aC-SHR 0.90, 95% CI 0.57-1.43, p=0.67) and non-liver-related mortality (aC-SHR 0.99, 95% CI 0.86-1.15, p=0.94; aC-SHR 1.40, CI 0.75-2.65, p=0.293).

Conclusion: In this territory-wide retrospective study, use of NSBB did not impact on liver-related and non-liver-related mortality in HCC patients over a follow-up period of 5 years.

Abstract Submission No. 100797

Shanghai China, 10Zhongshan Hospital Fudan University Shanghai China

Background: The global, randomized, phase 3 LEAP-002 study (NCT03713593) was conducted to evaluate lenvatinib plus pembrolizumab compared with lenvatinib plus placebo as first-line therapy in patients with advanced hepatocellular carcinoma (HCC). Efficacy and safety results for patients enrolled in LEAP-002 in China are reported.

Methods: Eligible patients had confirmed HCC, Child-Pugh class A liver score, ECOG PS score 0 or 1, and no main portal vein invasion. Patients were randomly assigned 1:1 to receive oral lenvatinib (8mg/day [bodyweight <60 kg] or 12mg/day [bodyweight ≥60kg]) plus either pembrolizumab (200mg IV every 3 weeks [Q3W]; ≤35 cycles) or placebo (saline IV Q3W). Dual primary end points were OS and PFS per RECIST v1.1 by blinded independent central review (BICR). Secondary end points included ORR per RECIST v1.1 by BICR and safety. Database cutoff was June 21, 2022.

Results: One hundred fifty patients were enrolled in China (lenvatinib plus pembrolizumab, n = 76; lenvatinib plus placebo, n = 74). Median follow-up (time from randomization to database cutoff) was 31.9 months (range, 28.1-37.5). Median OS was 32.3 months for lenvatinib plus pembrolizumab and 26.0 months for lenvatinib plus placebo (HR, 0.76 [95% CI, 0.50-1.17]). Median PFS was 8.3 months for both groups (HR, 0.86 [95% CI, 0.61-1.23]). Additional results are summarized in the Table.

Conclusion: China subgroup results were consistent with those of the global LEAP-002 population. OS, PFS, and ORR were numerically improved with the addition of pembrolizumab to lenvatinib, with a similar safety profile.

Abstract Submission No. 100895

Serum HBcAb level can predict the occurrence of hepatitis B related hepatocellular carcinoma.

Jing Chen1, Baiguo Xu2, Ying Liu2, Jiayin Wang2, Ruixin Song1, Anjing Liu2, Huiling Xiang2

1The Third Clinical College of Tianjin Medical University Tianjin, China, 2Department of Gastroenterology and Hepatology, Tianjin Third Central Hospital, Tianjin Key Laboratory of Extracorporeal Life Support for Critical Diseases, Institute of Hepatobiliary Disease, Tianjin, China, Tianjin China, 3Tianjin Tanggu Infectious Disease Hospital Tianjin China

Background: Serum hepatitis B core-related antibody (HBcAb) have always existed in the course of hepatitis B infection since the acute stage. Previous literatures have found that the quantitative detection of HBcAb is related to the occurrence of hepatitis B related hepatocellular carcinoma (HCC). In order to further explore the predictive significance of serum HBcAb levels in patients with chronic hepatitis B (CHB) for the occurrence of hepatitis B related HCC, we conducted this retrospective study.

Method: A total of 454 patients treated in our hospital from October 2018 to October 2019 were included. Serum HBcAb levels, surface antigen level, alpha fetoprotein (AFP) level, liver function and other clinical indicators were quantitatively measured at enrollment. The
Comparison of Alpha-Fetoprotein with Viral & Non-Viral Etiology in Hepatocellular Carcinoma Patients

1Centre of Gastroenterology-Hepatology HAM Akil, DR. Wahidin Sudirohusodo General Hospital Makassar Indonesia, 2Division of Gastroenterology-Hepatology, Department of Internal Medicine, Faculty of Medicine, Hasanuddin University Makassar Indonesia, 3Pertamina Royal Biriringkanaya Hospital Makassar Indonesia

Background: Alpha-fetoprotein (AFP) in serum is one of the diagnostic markers currently available for Hepatocellular Carcinoma (HCC). In Indonesia, HCC is the fourth most common cancer with an incidence of around 5.4%, while chronic hepatitis B virus (HBV) and hepatitis C virus (HCV) are the main etiology of HCC in all Asia-Pacific, western countries, and Africa, followed by non-viral etiologies. The efficacy of AFP monitoring is controversial and varies based on the etiology of chronic liver disease in patients with HCC. The aim is to analyze the correlation between alpha-fetoprotein serum and the etiology of hepatocellular carcinoma subjects.

Methods: This study was a retrospective database analysis of HCC patients diagnosed in Wahidin Sudirohusodo Hospital between 2018 and 2022. Information on patients' demography, laboratory (liver biochemistry/serology/virology), and radiology data were collected. Diagnosis of HCC according to the Asia-Pacific Association for the Study of the Liver (APASL). The threshold of AFP level of 400 ng/mL was evaluated against the etiologies of the subject.

Results: During the study period, a total of 337 HCC subjects were found. The majority were male with 257 (76.3%) patients and a mean age of 53.6 years old. Causes of the underlying liver were viral infection 244 (72.4%) and non-viral 93 (27.6%). Of the total patients, 172 (51.0%) had AFP over 400 ng/mL. Viral etiology was associated with higher AFP levels in serum (130 subjects vs 35 subjects, p<0.01).

Conclusions: Hepatocellular carcinoma with etiologic of viral infection was associated with a higher level of alpha-fetoprotein
RESULTS: The mean age was 59.94 ± 7.6 years. 44 (84.18%) were male. 20 (37.04%) had complete response, 10 (18.52%) had partial response, 9 (16.67%) had Stable disease and 15 (27.78%) had Progressive disease post-TACE. Mean SWE of focal lesion (FOL) at baseline was significantly lower in patients with CR (14.82 ± 4.76) compared to other groups PR (18.59 ± 5.31), SD (35.93 ± 8.7), PD (38.22 ± 14.07) (p= 26kpa (AUC=0.95, CI: 0.854 to 0.991; Sensitivity 100%, Specificity 79.1%, p=20kpa (AUC=0.79, CI:0.657-0.889, Sensitivity=83.3%, Specificity=67.7%). On Multivariate analysis, Lower baseline SWE FOL (aOR: 0.811, p=0.004) and lower AFP (aOR: 0.988, p=0.026) were found to be independently associated with Tumor Response.

Conclusion: Baseline Tumor Shear Wave Elastography and AFP can be used as predictors for Tumor response of HCC to TACE.

Abstract Submission No. 101027
O-0650
The distribution of BCLC 2022 stages among patients with Hepatocellular carcinoma

Zahabia Sohail1, zahabia Muhammad1, Asma Yaseen1, Syedda Ayesha1

1The Aga Khan University Karachi Pakistan

Objective: Primary liver carcinoma ranks as the seventh most prevalent cancer globally. Hepatocellular carcinoma (HCC) represents the predominant form of liver cancer, accounting for approximately 75% of all cases. The objective of this study is to ascertain the distribution of BCLC stages among patients presenting with HCC at a tertiary care hospital.

Method: A descriptive cross-sectional, observational study was carried out in the gastroenterology department of the Aga Khan University Hospital. The study included all patients, who presented in liver tumor board clinic with the diagnosis of HCC.

Result: A total of 66 patients were enrolled in the study, with mean age of 54.7 years. The primary cause of HCC was found to be Non-B non-C CLD in 39 cases (65%). BCLC -2022 staging was performed, with the majority of patients (n =42, 63.7%) falling into the BCLC-C category, followed by BCLC-D (n = 26, 39.3%).

Conclusion: The study highlights that a significant proportion of HCC patients are initially categorized as BCLC-C where some management decision can be offered. Early detection of HCC is recommended to offer improved treatment options to patients.

Abstract Submission No. 101041

A comparison of surgical resection and RFA for early-stage HCC patients with Child-Pugh class B

Takeshi Hatanaka1, 16, Satoru Kazizaki2, 16, Atsushi Hiraoka3, 10, Kazuya Kariyama4, 10, Toshifumi Tada0, 10, Toru Ishikawa10, Hidenori Toyoda10, Hideko Ohama10, Fujimasa Tada10, Atsushi Naganuma10, Kauzihiro Nosu0, Takashi Kumada10

1Department of Gastroenterology, Gunma Saiseikai Maebashi Hospital Maebashi Japan, 2Department of Clinical Research, National Hospital Organization Takasaki General Medical Center Takasaki Japan, 3Gastroenterology Center, Ehime Prefectural Central Hospital Matsuyama Japan, 4Department of Gastroenterology, Okayama City Hospital Okayama Japan, 5Department of Internal Medicine, Japanese Red Cross Himeji Hospital Himeji Japan, 6Center of Gastroenterology, Teine Keijinkai Hospital Sapporo Japan, 7Department of Gastroenterology, Saiseikai Niigata Hospital Niigata Japan, 8Department of Gastroenterology and Hepatology, Ogaki Municipal Hospital Ogaki Japan, 9Department of Nursing, Gifu Kyoritsu University Ogaki Japan, 10RELPEC group Ogaki Japan

Background: This study compared surgical resection (SR) and radiofrequency ablation (RFA) for early-stage HCC patients with Child-Pugh class B.

Methods: This retrospective study included 497 HCC patients with ≤ 3 nodules and tumors ≤ 3cm in diameter who initially received either SR (n=41) or RFA (n=456). The significant differences in patient background were adjusted by IPTW.

Results: The median ages were 72 and 68 years old in the SR and RFA group (p=0.3), with 26 and 305 patients being males (p=0.7). Child-Pugh score were 7, 8, and 9 in 34, 6, and 1 patients in the SR group and 262, 124, and 70 patients in the RFA group, respectively (p=0.003). The number of nodules was 1, 2, and 3 in 35, 6, and 0 patients in the SR group and 309, 109, and 38 patients in the RFA group, respectively (p=0.034). The maximum tumor diameter 2.2 and 1.8 cm in the SR and RFA group (p=0.002). The 5-, and 10-year RFS rates were 48.6%, and 30.4% in the SR group and 43.6%, and 34.9% in the RFA group, which did not reach a statistical significance (p=0.6). The 5-, and 10-year OS rates were 47.6%, and 19.5% in the SR group and 43.2%, and 15.3% in the RFA group, without a statistical significance (p=0.5). In the IPTW-weighted cohort, the differences in the RFS and OS rates between two groups were not observed (p=0.5 and 0.9, respectively).

Conclusions: RFA may be equally effective compared to SR for early-stage HCC patients with Child-Pugh class B.

Evaluation of circular RNA SMARCA5 as a novel biomarker for hepatocellular carcinoma

Mohamed Abdel-Samiee1, Hanan M. Bedair2, Elhamy A. Ahmed2, Mostafa G Elhelbawy1, Elaf A El-Banna2, Amal A El Sharrnoby2

1Hepatology and Gastroenterology, National Liver Institute, Menoufia University Shebin El-Kom Egypt, 2Clinical Pathology Department, National Liver Institute, Menoufia University Shebin El-Kom Egypt

Background: Hepatocellular carcinoma (HCC) is the sixth and fourth common cancer in worldwide and Egypt, respectively. Most patients with HCC are diagnosed at their advanced stages due to lack of early diagnosis biomarker, so they lose the best opportunity for therapy.

Objective: The aim of this study is to evaluate the level of circular RNA SMARCA5 and SMARCA5 mRNA expression as novel biomarkers for early detection of HCC.

Patients and methods: The study was conducted as a case control study included 159 subject, they collected from inpatient and outpatient patients clinics of national liver institute, Menoufia university and they were equally divided into 3 groups; Group I: 53 control subjects, Group II: 53 HCV cirrhotic patients and Group III: 53 HCC patients. Each patient underwent: full history taking, thorough clinical examination, radiological examination and assessment of serum Alpha-fetoprotein (AFP) and detection of circular RNA SMARCA5 and SMARCA5 mRNA genes by quantitative real time polymerase chain reaction (PCR).

Results: There were statistically significant difference among studied groups regarding AFP, SMARCA5, and CircSMARCA5 (P-value= 0.001, 0.001 & 0.001, respectively). CircSMARCA5 and SMARCA5 mRNA were significantly reduced in HCC group when compared to
HCV cirrhotic patients and controls. ROC analysis for early diagnosis of HCC showed that the area under curve (AUC) of CircSMARCA5 at cut-off point 4.55 yielded specificity of 83.8% and sensitivity of 91.7% while the AUC for AFP cut-off point 515 ng/ml yielding specificity of 89.2% and sensitivity of 91.3%.

**Conclusion:** CircSMARCA5 may serve as a potential predictor of HCC disease with better sensitivity than AFP.

**Integrative Characteristics of HBV -HCC after NUCs Long-term Antiviral Therapy**

Bobin Hu1, Hengkai Liang1, Rongming Wang1, Minghua Su1, Lu Wei1, Tumei Su1, Qingmei Li1, Qianbing Yin1, Yunfei Feng1, Jianning Jiang1

1The First Affiliated Hospital of Guangxi Medical University Nanning China

**Aims:** The integrated characteristics of Hepatitis B Virus (HBV)-related liver cancer after long-term antiviral treatment remain incompletely understood. This study aimed to explore the influence of integration events on clinical factors of HBV-related liver cancer using a long-term follow-up cohort undergoing antiviral therapy. Additionally, we aimed to analyze the characteristics of integration patterns.

**Methods:** This study enrolled 22 patients with HBV-related liver cancer, monitoring clinical indicators including HBV DNA and Hepatitis B Surface Antigen (HBsAg). Genome-Wide Association Study (GWAS) analyzed liver cancer tissues and detected HBV integration sites. Among them, 17 cases had HBV integration (Int group), while 5 cases had no HBV integration (N-int group). We analyzed clinical differences between the two groups and compared dynamic changes in HBsAg levels. Additionally, we explored genomic features at the HBV integration breakpoints.

**Results:** The participants were followed for nearly 11 years. Among them, 77.3% demonstrated HBV integration. The Int group consistently exhibited higher levels of HBsAg compared to the N-int group, accompanied by a slower decline. In the Int group, there were significant increases in telomerase reverse transcriptase (TERT) gene copy number, single nucleotide variations (SNVs) deletion number, and substitution number compared to the N-int group (P<0.05). Integration events primarily transpired close to chromosome termini and centromeres, indicating a preference for specific human genomic elements. Essential functional elements of the HBV genome were prone to integration.

**Conclusion:** After long-term antiviral therapy, HBV integration could still sustain a certain level of HBsAg. HBV integration resulted in an increased number of interrupted gene SNVs and could potentially impact chromosome stability and mitosis. Host genomic elements cooperated with HBV functional elements in integration events.

Abstract Submission No. 101185

**The causes of HCC in Turkey**

A.Kadir DOKMECI1

1Ankara University School of Medicine Ankara Turkey

**Background:** The incidence of chronic hepatitis infections. Also, the etiology of HCC has been changing with a growing role of metabolic (dysfunction) associated fatty liver disease (MAFLD).

**Results:** In the previous study, HBV, HCV and alcohol were the main causes of HCC with (56%), (23.2%) and (15.9%) in 207 patients respectively. The etiologic risk factors for HCC were HBV in 555 patients (57.6%), HCV (16.5%), and chronic alcohol (14.2%). Yalcın reported that HBV infection alone (45%), HDV co-infection (29%), HCV infection (15%) and unknown etiology (10%) were causes of HCC in southeastern Turkey. The result of another multicenter, retrospective cohort study including 1802 patients showed that HBV was the most common etiology (54%), followed by HCV (19%), MAFLD (10%), cryptogenic (8.6%), alcohol-related liver disease (3.6%), autoimmune liver diseases (0.9%).

It was reported that HBV infection (68.2%) was the leading etiology, followed by HCV infection (17.2%), HDV infection (5.5%), alcohol (6.4%), and MAFLD (3.5%).

**Conclusions:** Despite the national immunization program, HBV remains the leading cause of HCC in Turkey, followed by HCV, alcohol-related liver disease, cryptogenic MAFLD and HDV. Recently, MAFLD is increasingly involved in the etiology of HCC.

**The factors contributing to prolonged survival in the intermediate stage HCC using survival model.**

Masashi Ninomiya1, Jun Inoue1, Mio Tsuruoka1, Akitoshi Sano1, Kosuke Sato2, Satoko Sawahashi1, Masazumi Onuki1, Keishi Ouchi1, Atsushi Masamune1

1Tohoku University Hospital Sendai Japan

**Backgrounds:** The increase of treatments have made it possible to the more curative state in unresectable hepatocellular carcinoma. However, we do not know how much these therapies contribute to prognosis in real clinical practice. We applied our new developed survival model and compared them with actual survival, and analyzed the factors contributing to prolonged survival.

**Methods:** 101 cases from BCLC stage B from 2018 to 2023 were grouped by Kinki criteria as B1/B2/B3=37/56/8. 1) Overall survival was analyzed by Kaplan meier method. 2) Actual survival was determined in B1/B2/B3=26/41/6 cases. We compared them with predicted survival time calculating with survival model. The proportion of cases that exceeded the predicted survival time were extracted. The t-test was used to evaluate the survival factors contributing to the prolongation of the actual survival period.

**Results:** 1) Overall survival was 42.6/25.2/16.4 months. The mean predicted survival was 28.6/22.6/15.8 months. 2) Actual survival exceeded prediction in 17 patients (65.4%) in B1 and 23 (56.1%) in B2. Statistical analysis showed that actual survival time significantly exceeded predicted survival. Factors associated with prolonged survival were multiple TACE and RFA treatment in B1, and multiple TACE, ATZ+BV induction with treatment effect, and RFA treatment in B2.

**Conclusion:** Using our developed survival model, we analyzed the relationship of treatment contributing to prolonged survival in the intermediate stage. With the success or failure of TACE treatment is the key in the intermediate stage and ATZ+BV being effective in the B2 stage.
Safety of STRIDE regimen for advanced hepatocellular carcinoma and its optimal management

Takuya Yonemoto1, Sadahisa Ogasawara1, Sae Yumita1, Kisako Fujiwara1, Keisuke Koroki1, Masanori Inoue1, Kazufumi Kobayashi2, Masato Nakamura1, Naoya Kanagawa1, Soichiro Kiyono1, Takayuki Kondo1, Shingo Nakamoto1, Naoya Kato1
1Department of Gastroenterology, Graduate School of Medicine, Chiba University, chiba Japan

Background: Durvalumab/tremelimumab combination therapy (STRIDE) has been approved for advanced hepatocellular carcinoma (HCC). However, STRIDE, which contains a CTLA-4 inhibitor, is associated with a high incidence of immune-related/mediated adverse events (irAEs/imAEs), which are often difficult to manage. We analyzed clinical data on irAEs/imAEs that occurred after STRIDE administration at our hospital and investigated the management of irAEs/imAEs.

Methods: We retrospectively collected clinical data on 43 patients treated with STRIDE for advanced HCC between April and August 2023.

Results: IrAEs/imAEs requiring treatment with glucocorticoids occurred in 13 cases (30.2%), and high-dose glucocorticoids (≥1 mg/kg) were required in 7 cases (16.3%). The median duration from the start of STRIDE to the first irAE/imAE was 16 days (range: 6-51). IrAEs/imAEs leading to treatment discontinuation occurred in 4 cases, and disease progression was observed in 4 cases. In one case of enteritis, remission was not achieved with glucocorticoids alone and infliximab was added. In addition, in one case of cytokine release syndrome, remission was not achieved with glucocorticoids alone, necessitating tocilizumab. After tapering of glucocorticoids, durvalumab was reintroduced in 5 cases, with only one case of enteritis recurring.

Conclusions: STRIDE-induced irAE/imAE can be effectively managed by prompt administration of glucocorticoids in severe cases. It is also important to have adequate knowledge of additional treatment options in cases of inadequate response to glucocorticoids. Although there is a risk of recurrence of irAE/imAE, retreatment with durvalumab may be considered after successful control of irAE/imAE with glucocorticoids, especially if supported by the risk-benefit assessment.

Exploratory Effectiveness of Atezolizumab + Bevacizumab against uHCC Beyond Radiological Progression

Nobuhito Taniki1, Takaya Tabuchi2, Ryosuke Kasuga1, Po-Sung Chu1, Shunsuke Shiba1, Toshiyuki Tahara1, Yuriko Fujita1, Hitomi Hoshi4, Fumihiko Kaneko4, Keisuke Ojiro5, Akihiro Yamaguchi2, Seiichiro Fukuhara1, Yukishige Okamura1, Takanori Kanai1, Nobuhiro Nakamoto1
1Keio University Tokyo Japan, 2Saiseikai Utsunomiya Hospital Tochigi Japan, 3Yokohama Municipal Citizen's Hospital Kanagawa Japan, 4Saitama Municipal Hospital Saitama Japan, 5Tokyo Dental College Ichikawa General Hospital Chiba Japan, 6National Hospital Organization Saitama Hospital Saitama Japan, 7National Hospital Organization Tokyo Medical Center Tokyo Japan, 8Sano Kosei General Hospital Tochigi Japan

Background: The IMbrave150 trial allows the continuation of atezolizumab (Atezo) plus bevacizumab (Bev) beyond radiological PD until clinical benefits cease. This study investigates the effectiveness of continuing ICIs after initial radiological PD.

Methods: 122 unresectable HCC patients treated with Atezo plus Bev across 8 liver centers were enrolled. Patients with clinical benefits, despite PD as per RECIST 1.1, could continue treatment until unacceptable toxicity developed. Those who received two or more cycles of Atezo plus Bev after first PD were defined as beyond PD group. Their outcomes were compared with those who either switched to alternative therapies or discontinued chemotherapy post-first PD.

Results: 4 patients continued with Atezo plus Bev, 26 switched to other chemotherapies, and 15 discontinued treatments after the first PD. The median overall survival (OS) was 21.3 months in the beyond PD group versus 13.6 months in those who switched or discontinued treatment. Additionally, those who switched to alternative chemotherapy had a median OS of 23.1 months, while those receiving palliative therapy had 7.0 months. Macrovascular invasion (MVI) was identified as a significant prognostic factor in the beyond PD group, based on the Cox proportional hazard model. Notably, in the patients without MVI, beyond PD group had a significantly longer median OS compared to others.

Conclusion: The study suggests that there are patients who may benefit from continuing Atezo and Bev beyond PD, especially in those without MVI. Nevertheless, due to selection bias, more research is needed to find predictors define treatment efficacy.

Abstract Submission No. 101330
O-0658
Significance of Complete Response in Atezolizumab-Bevacizumab for Advanced Hepatocellular Carcinoma

Teiji Kuzuya1, Naoto Kawabe1, Yoshihi Hirooka1
1Department of Gastroenterology and Hepatology, Fujita Health University Toyoake Japan

Objective: To evaluate the characteristics and prognosis of patients who achieved complete response (CR) by mRECIST in patients with advanced hepatocellular carcinoma (HCC) treated with atezolizumab-bevacizumab (Atz/Bev).

Methods: 129 patients who received Atz/Bev in our hospital were included. The median age 75 years; Male 106 cases; ECOG-PS 0 96 cases; Child-Pugh score 5 82 cases; BCLC stage B 60 cases; median AFP 50.1ng/ml; median PIVKA-2 599mAU/ml.

Results: The best antitumor response (CR/PR/SD/PD+NE) to Atz/Bev alone was 16/45/36/32 in mRECIST (CRR 12.4%; ORR 47.3%). Median PFS was 258 days; for mRECIST, CR 588 days; PR 442 days; SD 209 days; PD+NE 42 days. Median OS was 644 days, with mRECIST: CR not achieved; PR 886 days; SD 644 days; PD+NE 173 days. Predictors of CR were fewer than 4 HCCs and no portal vein tumor thrombus at baseline. The median time to mCR was 105 days; AFP ratio was 0.330 at 2 weeks, 0.160 at 4 weeks, and 0.11 at 6 weeks; PIVKA-2 ratio was 0.575 at 2 weeks, 0.470 at 4 weeks, and 0.240 at 6 weeks. Six patients who underwent additional TACE achieved CR. Including these 6 patients, the median OS of the 22 CR patients was not reached. Of these, 18 patients achieved drug-free status.

Conclusions: Patients who achieved CR in mRECIST with Atz/Bev showed significant reductions in AFP and PIVKA-2 early in the course of treatment. CR achieved with Atz/Bev alone and with the addition of TACE can be expected to have an extremely favorable prognosis.

Abstract Submission No. 101333
O-0659
India Pabulum Index predicts short term mortality in patients with HCC : A Prospective study
Devika Madhu¹, Srijaya S Sreesh¹, Jithin John¹, Antony George¹, Aditya Verma¹, Nuzil Moopen⁴, Krishadas Devadas³

¹Department of Medical Gastroenterology Thiruvananthapuram India

Background and Aims: The presence of systemic inflammation predicts poor outcome in patients with malignancy. We attempted to evaluate the association of the inflammatory component of diet with mortality in patients with Hepatocellular carcinoma (HCC) using a novel score, India Pabulum Index (IPL index) and compared it with existing prognostic indices.

Method: We performed a prospective study of 6 months in 84 patients with Decompensated Chronic Liver Disease (DCLD) and HCC. Basic clinical parameters were obtained. IPL index was formulated as Prognostic Nutritional Index \((10 \times \text{serum albumin}[\text{g/dL}]) + (0.005 \times \text{lymphocytes/\text{µL}})\) evaluated in a South Indian cohort. Variables associated with Mortality were identified using Regression analysis and compared with other scores using ROC curves.

Results: The Short-term Mortality was 34.5% at 6 months. On univariate analysis, the predictors of mortality were IPL index \((p<0.001)\), BCLC score \((p<0.001)\), Portal Vein Thrombosis \((p=0.038)\), Hepatic Encephalopathy \((p<0.001)\), Child status \((p<0.001)\), Alpha fetoprotein \(>256\) \((p<0.007)\) and Neutrophil Lymphocyte Ratio \((\text{NLR})\) \((p<0.000)\). However, on multivariate analysis, IPL index \(<34.8\) \((p=0.001)\) and \(\text{NLR} >2\) \((p=0.039)\) were significantly associated with mortality. ROC-curve of IPL index estimated a cut-off value of 34.8 with sensitivity-89.66, specificity-90.91, positive predictive value-83.9 and negative predictive value-94.3. ROC for IPL index \((0.926)\) was higher than BCLC \((0.838)\), Hong Kong Liver Cancer \((0.786)\) and NLR \((0.778)\).

Kaplan Meier analysis showed that the mean survival was 5.887 ± 0.069 months in the high IPL index group \((>34.8)\) and 2.968 ± 0.346 months in the low IPL index group \((\leq 34.8)\) \((p<0.001)\). Multivariate analysis of the prognostic power of IPL index and BCLC using Cox regression model showed that a low IPL index had a Hazard ratio of 18.29 (95% CI (5.23-63.93)) vs 2.05 (95% CI (0.79-5.33)) for BCLC.

Conclusion: An IPL index of <34.8 predicts Short-term Mortality in patients with DCLD and HCC. It is an easy-to-use, sustainable and viable prognostic score that can be applied at bedside, to identify patients for dietary recompensation as a powerful tool to improve their survival.

Clinical Characteristics And Barcelona Clinic Liver Cancer Staging In Patient With HCC.

Gulzar khan¹

¹CPSP karachi Pakistan

Objective: This cross-sectional prospective study, conducted at the Gastroenterology Department of Jinnah Postgraduate Medical Center in Karachi between January 2018 and December 2022, aims to assess the distribution of Barcelona Clinic Liver Cancer (BCLC) stages in patients with Hepatocellular Carcinoma (HCC) in a tertiary care hospital. The study seeks to provide valuable insights into the clinical characteristics and staging of HCC within a specific population.

Methods: A total of 566 patients of both genders, all with confirmed HCC diagnoses, were included in the study. Data analysis was conducted using SPSS version 25.

Results: The study population had an average age of 59.3 years, with 58% being male and 42% female. The mean Model for End-Stage Liver Disease (MELD) score was 15±6. Hepatitis C Virus (HCV) was the leading cause of HCC, accounting for 70% of cases. The most frequently reported presenting complaints were abdominal distention and abdominal pain, followed by upper gastrointestinal bleeding. Upon Barcelona Clinic Liver Cancer (BCLC) staging, the majority of patients were classified as BCLC-D (40%), followed by BCLC-C (36%).

Conclusion: The study highlights a concerning trend in our population, with a significant proportion of HCC patients presenting in advanced stages, particularly within the BCLC-D category. Abdominal pain emerged as the most common symptom. Early detection of HCC is crucial to enable the timely implementation of more effective treatment strategies. These findings contribute to the global understanding of HCC presentation and staging, facilitating improved clinical management and patient outcomes on a broader scale.

Decoding the importance of AFP in HCC: Is it all it’s touted to be?

Sidharth Harindranath¹, Leela Shinde¹, Ankita Singh¹, Arun Vaidya¹, Biswa Ranjan Patra¹, Akash Shukla¹

¹Department of gastroenterology, Seth GS medical college and KEM hospital, Mumbai, India

Introduction: Serum alpha-feto protein (AFP) is the most widely used serological marker to establish a diagnosis of HCC and is a part of most standard guidelines on screening and diagnosis. We aimed to study the clinical relationship of AFP levels and tumor characteristics in patients diagnosed with HCC on surveillance.

Methods: A total of 126 patients (99 men, age 55±13.1 years) diagnosed with HCC on surveillance were recruited. AFP producing tumors (AFP+) were defined as AFP ≥10 ng/ml. Clinical and tumor characteristics were compared between patients with AFP producing versus non-AFP producing tumors (AFP-).

Results: A total of 85 (67.4%) were AFP+. Median CTP, MELD and AlBi score were 7 (IQR 5-14), 13 (IQR 6-35) and -1.7014 (IQR -3.63 - 0.53) respectively. The most common etiology was Hepatitis B (n=47 ; 37%) followed by NASH (n=37; 29.1%). AFP- had fewer number of lesions (9.8% vs 16.4%) but, the median size of the lesions was similar (5cm vs 5cm). AFP+ had a higher incidence of microvascular (30.5% vs 19.5%, p=0.17), macrovascular invasion (portal vein: 28.2% vs 12.2%; p=0.045, hepatic vein: 10.6% vs 7.3%; p=0.558) and extra hepatic metastases (16.5% vs 9.8%; p=0.313). Curative intent therapy could be offered to 20 (23.5%) Vs 22 (53.6%) in AFP+ and AFP- respectively.

Conclusions: AFP producing tumors have higher number of lesions, and increased incidence of vascular invasion and hepatic disease. Curative intent therapy could be offered to greater proportion of patients who were AFP+. Need better biomarkers for less aggressive disease.

Influence of Enterobacteria on the Response to Atezolizumab and Bevacizumab in patients with HCC

Kazuhiro Nousou¹, Kazuya Kariyama¹, Takashi Kumada², RELPEC Group¹,², HCC 48’

¹Department of Gastroenterology, Okayama City Hospital Okayama Japan, ²Gifu Kyoritsu University Ogaki Japan

Background: Numerous studies suggest that alterations in the microbiome can impact the efficacy of immune checkpoint inhibitors. The use of proton pump inhibitors or antibiotics is considered a risk factor

Abstract Submission No. 101436

O-0664
for diminished survival, while the presence of butyrate-producing enterobacteria appears to have a potentially positive effect. However, the specific influence of enterobacteria on patients with hepatocellular carcinoma (HCC) remains unclear.

**Methods:** We conducted a retrospective analysis of 747 HCC patients undergoing treatment with atezolizumab and bevacizumab, examining the impact of orally administered butyrate-producing enterobacteria on treatment efficacy and overall survival. Additionally, we reviewed reports examining the effects of proton pump inhibitors and antibiotics on treatment outcomes.

**Results:** While the objective response in patients taking butyric acid-producing enterobacteria was higher compared to the control group (29.7% vs. 26.4%), no statistically significant differences were noted. Similar trends were observed in disease control rates (77.8% vs. 72.7%). Median survival time showed no significant difference between the two groups (20.0 months vs. 21.4 months), even after adjusting for patient background. Despite one study reporting a connection between pretreatment antibiotics and reduced therapeutic response, our analysis did not reveal a significant impact of antibiotics or proton pump inhibitors.

**Conclusions:** Our study did not identify a clear influence of enterobacteria on the treatment outcomes of patients with hepatocellular carcinoma receiving atezolizumab and bevacizumab; however, prospective study is needed to confirm the effect.

**Abstract Submission No. 101443**

1Department of Gastroenterology and Hepatology, Musashino Red Cross Hospital Tokyo Japan

**Background:** Immune checkpoint inhibitor therapy has dramatically benefited cancer patients, particularly patients undergoing long-lasting effectiveness. However, durable responses are not well elucidated in real-world clinical practice. We aimed to clarify the durable response rate and the significance of atezolizumab plus bevacizumab (Atez+Bev).

**Methods:** This single-center retrospective study enrolled 134 patients with unresectable hepatocellular carcinoma (HCC) who underwent Atez+Bev treatment. We evaluated radiological response according to RECIST ver 1.1 at 6-8 weeks and every 8-12 weeks thereafter. The “durable response” was defined as a maintained response (CR/PR/SD) >6 months and received Atez+Bev >6 months.

**Results:** Among enrolled patients, 84 patients received AtezBev as the 1st-line treatment. In the 1st-line treated patients, SD/PR/CR was achieved in 42(50%)/20(24%)/2(2%), respectively. Among these, durable response was achieved in 40% of SD, 75% of PR, and 100% of CR. Patients who achieved durable responses survived significantly longer than those who did not (p=0.02). The durable response rate was significantly higher in the 1st-line group than in the 2nd or later-line treated patients (40% vs. 18%, p=0.02). The durable response rate in the 2nd or later-line group was 24% for patients who achieved SD and 67% for patients with PR. Patients whose AFP decreased under 800 ng/mL were independently associated with OS. The ORR and DCR were 35% and 76%, and 44% and 75% using RECIST and mRECIST, respectively. Two (10%) patients had significant downstaging and underwent successful curative-intent microwave ablation.

**Conclusions:** Response rates in this real-world cohort were comparable to the registration trial. Atezolizumab-bevacizumab followed by curative microwave ablation was achieved in two cases.

**LUS and ICG Fluorescence Navigation in Laparoscopic Anatomical Liver Resection**

Hongguang Wang1

1Department of Hepatobilary Surgery, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College Beijing China

Anatomical resections, which include the complete removal of an anatomical area that is defined by the vascular supply of the Glissonian branches, have been shown to significantly improve the oncological outcomes and to reduce local recurrence compared with nonanatomical resections in patients with HCC. By approaching the hilum according to specific gates and landmarks including Laennec’s capsule, one could identify and divide the pedicle of each segment or subsegment, aiming to a true anatomical resection. The hepatic intersegmental/sec- tional plane is defined by the border or watershed of each order portal venous territory. Hepatic veins coursing intersegmental/sec- tional planes are defined as intersegmental/segmental veins. They can play a role of landmark to divide the liver parenchyma appropriately by continuously exposed in the cutting plane. LUS and ICG staining are

Background: With the rapid aging population, the opportunity for surgery among individuals aged 80 years and older has increased. This study aims to evaluate the appropriateness of such procedures.

Methods: A retrospective review of cases involving liver cancer surgery in patients aged 80 years and above, performed at our hospital from January 1, 2013, to December 31, 2022, was conducted.

Results: The study encompassed 44 cases: 28 males and 16 females, with a median age of 82 years (range: 80-89). Surgical cases gradually increased from 2013-2017 (20 cases, 16.2%) to 2018-2022 (24 cases, 19.8%). Background liver diseases included HBV (3), HCV (17), MASLD (6), alcohol-related (4), and others (14). Pre-existing malignancies were observed in 17 cases (38.6%). Most cases (86.3%) were independent in activities of daily living (ADL), while 13.6% required some form of support. Surgical techniques varied, with partial resection (41%) and anatomical major liver resection (59.1%) being predominant.

Conclusion: Surgical interventions in liver cancer patients aged 80 and above at our institution displayed satisfactory short-term outcomes and comparable long-term results to national surveys. However, cases revealed early discontinuation of follow-up due to declining ADL and a lack of preparedness for appropriate post-recurrence treatments.

Abstract: A 84-year-old man, who refused antiviral therapy for chronic hepatitis C, had been followed up every 6 months for surveillance of hepatocellular carcinoma (HCC). In June X-1, a 20mm hypoechoic mass was found in S8 of the liver. Further examination with EOB-MRI and CT angiography findings were undiagnostic for HCC. In January X, he noticed a 6-cm mass in the left anterior chest wall, and visited us. Chest CT showed bone tumors on 1st and 7th rib. Biopsy of the mass showed plates of cords of cells lined by endothelium and immunostaining of the hepatocyte marker HEP-PAR1 was strongly positive. This led to the diagnosis of rib metastasis of HCC. EOB-MRI of the liver revealed the enlarged S8 mass with intrahepatic metastasis in S6 lesion. With a diagnosed as HCC stage IVB and his liver function as Child-Pugh class A, a combination of atezolizumab and bevacizumab (Atezo/Bev) were initiated in May X. For rib metastases, extracorporeal radiation therapy was also added. The bone tumors shrank in August X. The patient is currently receiving 16 courses of Atezo/Bev and maintaining CR for 1.5 years. Discussions: It has been suggested that the combination of immune checkpoint inhibitors and radiation therapy may have a synergistic effect, in which neoantigens resulting from DNA damage in irradiated tumors stimulate antigen-presenting cells, which activate T cells and exert an anti-tumor immune effect on residual tumor cells after irradiation. In this case, combination use of radiation therapy may have enhanced the effect of immune checkpoint inhibitors.

TACE with a fine cisplatin powder and porous gelatin particles for TACE-naïve multifocal HCC

RUI SATO¹, Michihisa Moriguchi², Takeshi Aramaki¹, Atsushi Saiga¹, Kazuhisa Ashara¹
¹Division of Interventional Radiology, Shizuoka Cancer Center Shizuoka Japan, ²Molecular Gastroenterology and Hepatology, Graduate School of Medical Science, Kyoto Prefectural University of Medicine Kyoto Japan

Purpose: A Japanese Interventional Oncology group showed the efficacy and safety of nonselective transcatheter arterial chemoembolization (TACE) with a fine cisplatin powder (65mg/m2) and porous gelatin particles without lipiodol for extensive multifocal hepatocellular carcinoma (HCC)(1). The aim of this study is to evaluate the efficacy and safety of this type of TACE for the whole liver in a single center.

Material and methods: We retrospectively reviewed our medical records of TACE-naïve multifocal HCC patients (Child Pugh A, up to 7 out) who had undergone TACE for the whole liver with a fine cisplatin powder and porous gelatin particles between 2006 and 2019.

Results: There was 60 patients. The median age of the patients was 71 years (range 35-88). Child Pugh 5 was 41 patients (68.3%). The median maximum size of tumors was 26mm (range 8-184mm). Overall survival was 30.3 months. Progression free survival was 4.8 months. Initial evaluation with contrast enhanced CT was done (mean 45days later) with modified RECIST (Response Evaluation Criteria in Solid Tumors). Overall response rate was 65% (complete response 13, partial response 26). Disease control rate was 86.7% (stable disease 13, Progressive disease 8). At the time of initial evaluation, 8 patients’ liver function had dropped to Child Pugh B (13.3%).

Conclusion: Although TACE with a fine cisplatin powder and porous gelatin particles for the whole liver was effective for the tumor reduction, we have to be careful not to lose liver function for further post-treatment.

Abstract Submission No. 101658

Current status of initial treatment for elderly patients with hepatocellular carcinoma

Hidenori Kido¹, Tatsuya Yamashita¹, Taro Yamashita¹
¹Graduate School of Medical Science, Kyoto Prefectural University of Medicine Kyoto Japan

Methods: 12 patients underwent GSA, MRI, and ICG-R15 testing before treatment, 1 month after treatment, and 3 months after treatment. All patients underwent imaging studies and blood tests at the beginning of treatment, 1 month after treatment, and 3 months after treatment ended. The evaluation items were as follows: 1) changes over time in Child-Pugh classification, ICG-R15, and ALBI values before and after SBRT; 2) changes over time in GSA count and ICG; and 3) selection of the optimal sequence for recognizing radiation hepatitis on MRI.

Results: The ICG values were 14.4 before RT, 17.1 after 1 month, and 17.6 after 3 months. ICG worsened after 1 month of treatment, but was similar after 3 months. ALBI values were -2.61 before RT, -2.67 after 1 month, and -2.71 after 3 months. ALBI worsened slightly over time.

Conclusion: Regarding the ICG-R15, there was an average worsening of 2.8 after 1 month of treatment compared with before SBRT, but only of 0.5 between 1 month and 3 months after SBRT. Therefore, evaluation using ICG-R15 after SBRT after 1 month alone may be sufficient.
Background: To decide the treatment strategy for hepatocellular carcinoma (HCC), not only hepatic reserve and tumor conditions, but also comorbidities and age are considered. There are no clear criteria for comorbidities and age as indications for treatment for HCC.

Methods: We reviewed 317 patients who underwent standard treatment (resection or RFA) for HCC of less than 3 cm and 3 or less during the period from January 2009 to December 2018 at our institution and analysis background liver disease, tumor conditions, hepatic reserve, and prognosis Furthermore, we compared across the age groups of 65 years (WHO criteria for elderly patients) and 80 years (age group excluded from the SURF study).

Results: In 293 of 317 patients (92%), prognosis, including recurrence and cause of death, was traceable. Overall, 62.8% had a single tumor, mean tumor diameter 18.9 mm, Child-Pugh Score A in 79.4%, median OS 70 months, median RFS 24 months, 3-year survival 78.9%, 5-year survival 55.8%, and other disease death. Of the 317 patients, 91 were younger than 65 years, 178 were 65-79 years, and 48 were older than 80 years. Tumor conditions and liver reserve were similar for all ages. For patients <65/65-79/80< years old, median OS was 85/68/55 months, median RFS was 27/24/24 months, 3-year survival rate was 82/79/69%, and 5-year survival rate was 69/59/48%. The cause of death in 43/37/33% of the patients was liver cancer death and 31/39/53% from other diseases. 2 in the 65-79 age group and 2 in the 80< age group had comorbidity as a prognostic factor before initial treatment, and only one of each of these patients actually died of other causes.

Conclusion: Tumor conditions and hepatic reserve were similar in each generation, but the prognosis was significantly worse in the elderly, with more deaths from other causes. It should be noted that these results were obtained even in a population in which the standard of care was judged to be appropriate after discussion at the Cancer Board. The results suggest that a new criteria for determining Fit or Unfit for standard treatment is needed.

Relevance of the study: The cardiotoxic effect of chemotherapy can be manifested by a large spectrum of changes on the ECG, among which tachycardia, changes in the ST segment and T wave, ectopic atrial rhythms, intraventricular blockages, prolongation of the QTc interval, and complete blockage of the right leg of the Gis bundle and blockage of the anterior-upper branching were recorded in 4 patients, 2 of them received gemcitabine and 2 oxaliplatin therapy. Resting heart rate was significantly higher in the targeted therapy group (88.4±12.8 per minute versus 74.3±10.8 per minute, p=0.047). Also, resting heart rate was significantly higher in the targeted therapy group versus the TACE group (88.4±12.8 per minute versus 74.3±10.8 per minute, p=0.047).

Conclusions: Early detection of initial abnormalities, including on an ECG, can help to correct chemotherapy and prevent fatal complications in this group of severe patients.

Impact of surgical resection of initially unresectable HCC after LEN or ATZ+BEV treatment

Yoshihiro Sakamoto1, Hirokazu Momose1, Naohiro Okano1, Ryota Matsuaki2, Nobuhiro Hasui3, Masaharu Kogure1, Yutaka Suzuki1, Shuichi Hironaka1

1Kyorin University Hospital Tokyo Japan

Background: Recent introduction of immune-checkpoint inhibitors or targeted therapy has facilitated the surgical resection after drug therapy for initially unresectable hepatocellular carcinoma (HCC).

Methods and Patients: Between 2018 and 2023, 39 consecutive patients who received lenvatinib (LEN) or atezolizumab + bevacizumab (ATB) for initially unresectable HCC.
patients with 4 or more nodule (n = 14), refractoriness to TACE (n = 11), extrahepatic diseases (n = 16) or v3 or v3 (n = 8) and others (n = 3).

Results: Responses to LEN and ATB were PR in 5% and 20%, SD in 53% and 40%, PD in 10% and 0%, respectively in mRECIST. No significant difference was found in the disease control rates between LEN and ATB (63% vs 40%, p = 0.15). Surgical resection was performed in five patients (13%) who received LEN (n = 2) and ATB (n = 3). Progression survival was better in 5 patients who underwent surgery than in 18 patients who continued non-surgical treatments after first therapy (median, 18 vs 6 months, p = 0.02). However, no significant difference was found in disease specific overall survivals between patients undergoing surgery and non-surgical treatments (median, 23 vs 22 months, p = 0.24).

Conclusion: Aggressive surgery for initially unresectable HCC after LEN and ATB treatments offered favorable progression free survival. Local therapy after systemic therapy may play an important role in the treatment of advanced HCC.

Influence of DOAC on bleeding events of atezolizumab and bevacizumab therapy
Masaki Kawabata1, Tasuku Nakabori1, Kaori Mukai1, Kazuyoshi Ohkawa1
1Osaka International Cancer Institute Osaka Japan

Background: Bevacizumab has the bleeding risk, because bevacizumab inhibits angiogenesis. DOACs (Direct Oral Anti Coagulants) are increasingly used in cancer patients because of their attractive characteristics such as no coagulation test monitoring required. There are concerns that the combination of bevacizumab and DOACs may increase bleeding events. We analyzed the influence of DOACs on bleeding risk during atezolizumab and bevacizumab regimens (Atezo/Bev).

Methods: The retrospective study included 59 patients with hepatocellular carcinoma (HCC) and 82 patients with lung cancer who received Atezo/Bev. Exclusion criteria were the administration of antithrombotic agents other than DOACs.

Results: No significant difference was observed in bleeding events between the DOAC group (1/11 patients, none with Gr.2 or higher) and the no-antithrombotic drug (14/130 patients, 4 patients with Gr.2 or higher) groups (p=1.000). Regarding factors contributing to bleeding events, DOAC administration had a HR of 1.357; 95% CI: 0.175-10.54; p=0.770. Multivariate analysis showed that hypalbuminemia was an independent factor contributing to bleeding (HR 0.298; 95% CI: 0.105-0.847; p=0.006). As for analysis of only patients with HCC, bleeding events were not observed in the DOAC group (5 patients), but occurred in 8 patients in the no-antithrombotic agent group (8/54 patients, 3 patients with Gr.2 or higher) with no significant difference (p=0.808). High ALBI score was an independent factor contributing to bleeding (HR 9.083; 95% CI: 1.118-73.76; p=0.039).

Conclusions: In the DOAC group, there were no cases in which Atezo/Bev was discontinued due to bleeding. Atezo/Bev may be safely administered under surveillance in patients taking DOAC.

Background: Systemic therapy is mainly indicated for HCC patients in advanced stage. It is difficult to evaluate the individual therapy whether it is appropriate or not in real world. Recently, we have developed a Weibull model prediction of survival duration in patients with intermediate stage (Sci Rep 2023). Based on this model, we next aimed to develop a new model to predict survival duration in patients with advanced stage.

Methods: 750 patients from 2005 to 2017 were enrolled in this cohort. Any therapies were admitted but just one TKI, Sorafenib, could be used. The survival related factors were extracted by the cox proportional hazard regression model. The expectation of survival duration model was developed by exponentiated Weibull distribution.

Results: The median ALBI score was -2.18. Macrovascular invasion shown 76.7% and extrahepatic metastases was 35.3%. The multivariate Cox proportional hazards analysis showed significant difference in ALBI score including with T-bil, albumin and AFP, age, naive or recurrence, the number of nodules, the size of the largest nodule, the presence of macrovascular invasion and extrahepatic metastases. The survival curb continuously corresponded with exponentiated Weibull distribution. The new survival model for patients with BCLC C stage was developed based on these nine factors.

Conclusion: This survival model is useful in epidemiologic research and in clinical practice for patient counseling, prognostication and comparison with survival duration after multi MTA era.

Biomarker discovery for HCC detection and prognosis via plasma cfDNA methylome profiling
Xiaozhou Zhou1,2, Pin Cui1, Xinfeng Sun1,2, Jialing Sun1,2, Weihuang He3, Bingding Huang4, Ruyun Ruan4, Zhiyi Han1,2, Yuanke Pan1, Jinxin Zhu1, Jing Li5, Xin Zhong5, Wenxing Feng6, Mengqing Ma1,2, Rui Hu1,2
1Shenzhen Traditional Chinese Medicine Hospital shenzhen China, 2Department of Liver Disease, the fourth Clinical Medical School, Guangzhou University of Chinese Medicine Shenzhen China, 3Shenzhen Rapha Biotechnology Incorporate Shenzhen China, 4College of Big Data and Internet, Shenzhen Technology University Shenzhen China

Purpose: This study aims to develop methods for detection, prognosis and stratification of HCC using plasma cfDNA methylome profiling using whole genome bisulfite sequencing (WGBS) and targeted bisulfite sequencing (TBS).

Experimental Design: Plasma cfDNAs were isolated from a total of 311 participants including 70 healthy individuals, 46 patients with HBV, 45 patients with cirrhosis, and 150 HCC patients. Two cfDNA
methylations were performed using WGBS and TBS, respectively, and a machine learning method for cancer detection based on genome wide differentially methylated regions (DMRs) between HCC and other groups was used to establish early detection, prognosis and stratification model for HCC.

**Results:** WGBS analysis achieved overall sensitivity of 85.37% at 82.35% specificity to discriminate all stages of HCC patients from healthy people, and sensitivity of 92.31% at 88.24% specificity to discriminate early stage HCC patients from healthy people, while the TBS analysis showed better performance of 95.65% sensitivity at 83.33% specificity to discriminate all stages of HCC patients from healthy people, and sensitivity of 85.71% at 83.33% specificity to discriminate early stage HCC patients from healthy people. Additionally, a number of significant DMRs between HCC and non-cancer groups were identified, providing candidate biomarkers for HCC detection and prognosis.

**Conclusions:** This study provides preliminary proof for the feasibility of plasma cfDNA methylomes profiling for HCC detection, staging and prognosis. WGBS showed genome wide methylation profile while TBS provide in-depth analysis of highly relevant genomic regions with discrepancies of methylation levels between different groups yielding potential biomarkers for HCC detection.

Peking University 302 Clinical Medical School Beijing China, 4. Chinese PLA Medical School Beijing China, 5. Hospital of North China Electric Power University Beijing China, 6. JCU School of Public Health and Primary Care, Faculty of Medicine, The Chinese University of Hong Kong Hong Kong SAR China, 7. Hepatobiliary Division, Department of Internal Medicine and Hepatitis Center, Kaohsiung Medical University Hospital Kaohsiung Taiwan

**Background:** The risk of hepatocellular carcinoma (HCC) occurrence following anti-viral therapy in patients with chronic hepatitis C (CHC) remains unclear. The study aimed to estimate HCC occurrence rate following sustained virological response (SVR), among different subgroups.

**Methods:** A search was performed for articles published between January 1, 2017 and July 2022. Studies were included if they assessed HCC occurrence rate in CHC patients following anti-HCV therapy. Random effect meta-analysis was used to synthesize the results from individual studies.

**Results:** A total of 27 studies including 33,500 patients (IFN-based=6, DAA=21; prospective=10, retrospective=17) were included in the review. HCC occurrence was significantly lower in CHC patients with SVR (1.52 patient-year (py), 95% CI 1.45, 1.61) in CHC patients who achieved SVR which was significantly lower than those in non-responders (0.23 py, 95% CI 5.29, 7.34). Stratified by HCV treatment regimens, HCC occurrence following SVR was 1.11 per 100 py (95% CI 0.95, 1.30) and 1.59 per 100 py (95% CI 1.50, 1.68) in IFN- and DAA-treated based studies. HCC occurrence was 1.18 per 100 py (95% CI 1.12, 1.24) across all fibrosis stages and rose to 1.62 per 100 py (95% CI 1.39, 1.89) in studies focussed on advanced fibrosis or cirrhosis. Further meta-regression analysis showed that neither treatment type nor liver fibrosis stage was associated with a higher HCC occurrence rate.

**Conclusion:** HCC occurrence was significantly lower in SVR population than in NR population. However, we found no significant difference in HCC risk following SVR between two therapies or different fibrosis stages.

**Association of ABO blood groups and Rhesus factor with primary liver cancer:**

**Liyan Dong**<sup>1,2</sup>, **Yuhang Yin**<sup>1,2</sup>, **Huiyuan Lu**<sup>1-3</sup>

1. General Hospital of Northern Theater Command Shenyang China, 2. China Medical University Shenyang China, 3. Shenyang Pharmaceutical University Shenyang China

**Background:** Primary liver cancer (PLC) is one of the most common cancers worldwide. ABO blood groups and Rhesus (Rh) factor are inherent characteristics. Their association with the presence of PLC remains unclear in cirrhotic patients.

**Methods:** Patients with liver cirrhosis who were consecutively admitted to our hospital from January 1, 2010 to June 30, 2014 were retrospectively screened. Logistic regression analyses were performed to explore the association of ABO blood groups and Rh factor with PLC in cirrhotic patients. Adjusted odds ratios (aORs) with 95% confidence intervals (CIs) were calculated after adjusting for gender, age, family history of liver cirrhosis, HBV-DNA positivity, and etiology of cirrhosis. Subgroups analyses were performed according to different etiologies of liver cirrhosis.

**Results:** Overall, 1158 cirrhotic patients without PLC and 240 cirrhotic patients with PLC were included. After adjusting for confounding factors, non-O blood group (aOR=0.763; 95%CI=0.449-1.298, p=0.319), A blood group (aOR=0.643; 95%CI=0.332-1.246, p=0.191), B blood group (aOR=0.835; 95%CI=0.453-1.540, p=0.564), AB blood group (aOR=0.888; 95%CI=0.363-2.170, p=0.795), and Rh (+) (aOR=0.239; 95%CI=0.036-1.571, p=0.136) were not independently associated with PLC in cirrhotic patients. In the subgroup analysis of HBV-related cirrhotic patients, the proportion of A blood group was significantly lower in cirrhotic patients with PLC than those without (24.17% vs. 33.99%, p=0.001; however, in those of HCV and alcohol-related cirrhotic patients, the proportions of ABO blood groups and Rh factor were not significantly different between the two groups.

**Conclusions:** ABO blood groups and Rh factor may not be associated with the presence of PLC in liver cirrhosis.

1. Division of Gastroenterology, Department of Internal Medicine, King Chulalongkorn Memorial Hospital, Faculty of Medicine, Chulalongkorn University Bangkok Thailand, 2. Center of Excellence for Innovation and Endoscopy in Gastrointestinal Oncology, Faculty of Medicine, Chulalongkorn University Bangkok Thailand

**Background/Aim:** Given limited ultrasound sensitivity in hepatocellular carcinoma (HCC) surveillance, and few prospective studies exploring non-contrast abbreviated MRI (NC-AMRI) for this purpose,
this study aimed to assess diagnostic performance of NC-AMRI in detecting HCC.

**Materials and Methods:** This ongoing prospective study involves cirrhotic patients with LI-RADS LR-2, LR-3, and LR-4 findings in MRI. Patients underwent one to three complete contrast-enhanced MRI rounds (CE-MRI). NC-AMRI included diffusion-weighted (DWI), T1-weighted gradient imaging (T1WI), and T2-weighted imaging (T2WI-FS). Diagnostic performances of surveillance protocols were analyzed.

**Results:** In 101 follow-up CE-MRI examinations, the median (IQR) age of patients is 64 years (55-70), comprising 61% males and 39% females. Hepatitis C (37%) and hepatitis B (33%) were the predomina

**Factors enhancing local control of TACE recommended in BCLC strategy 2022-update for BCLC-0&A HCC**

Ken Kageyama1, Kazuo Asano1, Akira Yamamoto1, Atsushi Jogo1, Mariko Nakano1, Kazuki Murai1, Masanori Ozaki1, Shohei Harada1, Kazuki Matsuishi1, Yuki Sakai1, Eisaku Terayama1, Yukio Miki1

1Osaka Metropolitan University Osaka Japan

**Backgrounds:** BCLC strategy 2022-update recommended TACE as an alternative treatment when curative treatment is not possible. This study aims to clarify therapeutic effects of TACE on single, treatment-naive HCC corresponding to BCLC stage 0&A HCC. Factors enhancing local control effect of TACE were retrospectively evaluated.

**Methods:** This study investigated cases of Lip-TACE performed between 2010 and 2019. Factors contributing to local control effect were age, sex, Child-Pugh Score, tumor diameter, location, AFP, PI伏KA-II, number of vessels to tumor, and Lipiodol accumulation around tumor. Local recurrence free survival (LRFS) was statistically evaluated using Kaplan-Meier curves.

**Results:** Seventy-three cases were included in this study. Median LRFS for 73 nodules was 76.3 months. The peripheral tumor-location group, the single feeder group, and the group with Lipiodol accumulation around tumor had a longer LRFS than the central tumor group, the multiple feeder group, and the group without Lipiodol accumulation around tumor, respectively (median LRFS: Unreached vs. 9.9 months; Unreached vs. 5.6 months). In multivariate analysis, the peripheral tumor group, the multiple feeder group, and the group with Lipiodol accumulation around tumor showed a high hazard ratio for shortening LRFS (hazard ratio; 3.81; 1.80; 1.98) with Lipiodol accumulation around tumor. In multivariate analysis, the peripheral tumor group, the multiple feeder group, and the group with Lipiodol accumulation around tumor showed a high hazard ratio for shortening LRFS (hazard ratio; 3.81; 1.80; 1.98).

**Conclusions:** Factors enhancing local control effect of TACE for BCLC stage 0&A HCC was identified.

**Backgrounds:** BCLC strategy 2022-update recommended TACE as an alternative treatment when curative treatment is not possible. This study aims to clarify therapeutic effects of TACE on single, treatment-naive HCC corresponding to BCLC stage 0&A HCC. Factors enhancing local control effect of TACE were retrospectively evaluated.

**Methods:** This study investigated cases of Lip-TACE performed between 2010 and 2019. Factors contributing to local control effect were age, sex, Child-Pugh Score, tumor diameter, location, AFP, PI伏KA-II, number of vessels to tumor, and Lipiodol accumulation around tumor. Local recurrence free survival (LRFS) was statistically evaluated using Kaplan-Meier curves.

**Results:** Seventy-three cases were included in this study. Median LRFS for 73 nodules was 76.3 months. The peripheral tumor-location group, the single feeder group, and the group with Lipiodol accumulation around tumor had a longer LRFS than the central tumor group, the multiple feeder group, and the group without Lipiodol accumulation around tumor, respectively (median LRFS: Unreached vs. 9.9 months; Unreached vs. 5.6 months). In multivariate analysis, the peripheral tumor group, the multiple feeder group, and the group with Lipiodol accumulation around tumor showed a high hazard ratio for shortening LRFS (hazard ratio; 3.81; 1.80; 1.98). LRFS was significantly longer in these 3-factor integration group than in the others (Unreached vs. 16.2 months). The 1-year local control rate was 85.1% vs. 54.9%, and Both 3- and 5-year local control rates were 77.6% vs. 36.5%.

**Conclusions:** Factors enhancing local control effect of TACE for BCLC stage 0&A HCC was identified.
Insulin Growth Factor-1 Level as a Disease Course Predictor in Hepatocellular Carcinoma Patients

Muhammad Bilal Saifulhaq1, Tohari Amin1, Syifa Mustika2, Alfatea Pintari Rahmi3
1Internal Medicine Department, Saiful Anwar Regional Hospital and Brawijaya University Malang Indonesia, 2Gastroenterology Division of Internal Medicine Department, Saiful Anwar Regional Hospital, Brawijaya University Malang Indonesia, 3Medical Faculty of Brawijaya University Malang Indonesia

Background: The insulin-like growth factor (IGF) axis has important autocrine, paracrine and endocrine roles in growth promotion. Alterations of the IGF system have recently been implicated in the pathogenesis of several malignancies, but the relation to hepatocellular carcinoma (HCC) risk is unclear. This study aimed to determine whether serum IGF-1 level predicts the progression and survival in HCC patients.

Methods: According to the Preferred Reporting Items for Systematic Reviews and Meta-Analysis (PRISMA) guidelines, we systematically searched Pubmed, EMBASE and Cochrane Central database through the end of October 2023 to identify all studies reporting association between serum IGF-1 level and HCC. A total of 13 cohort studies with calculation of relative risk (RR) of serum IGF-1 for HCC time-to-progression (TTP) and overall survival (OS) were subjected to statistical analysis using STATA 17. We assessed the ability of serum IGF-1 to predict HCC progression and survival using random effect model to estimate pooled RR. Heterogeneity among studies was assessed by the Cochran’s Q and I² statistics. Publication bias was analysed using a Begg funnel plot and Egger test.

Results: The meta-analysis of selected studies showed that low level of serum IGF-1 significantly predicted shorter TTP (RR 2.36; 95% CI 1.51-3.68) and poorer OS (RR 2.17; 95% CI 1.72-2.74) in HCC patients, p value=0.00.

Conclusions: IGF-1 serum level independently predicted the progression and survival in HCC patients. Larger scale studies are needed to investigate the relationship explanation.

Efficacy and safety of arterial infusion chemotherapy in patients with Child-Pugh class B

Masatsugu Ishii1, 2, Satoshi Itano3, Osamu Itano3
1Department of Gastroenterology, Kurume Chuo Hospital. Fukuoka Japan, 2Department of Hepato-Biliary-Pancreatic Surgery, Tochigi Cancer Center. Tochigi Japan, 3Department of Hepato-Biliary-Pancreatic & Gastrointestinal Surgery, School of Medicine, International University of Health and Welfare. Chiba Japan

Introduction: Although many treatment options are available for patients with advanced hepatocellular carcinoma and Child-Pugh class A, those for patients with Child-Pugh class B remain limited. We aimed to assess the safety and efficacy of hepatic arterial infusion chemotherapy using 5-fluorouracil and cisplatin in patients with advanced hepatocellular carcinoma and Child-Pugh class B.

Methods: Sixty patients who received hepatic arterial infusion chemotherapy with 5-fluorouracil and cisplatin at Kurume Chuo Hospital between April 2012 and March 2021 were recruited. Cisplatin (30 mg administered over 2 hours) and 5-fluorouracil (1,250 mg, 72-hour constant infusion) were administered to the tumor-feeding artery every 2 weeks. The primary endpoint was overall survival, while the secondary endpoints were progression-free survival and adverse effects.

Results: Among the 60 patients, Child-Pugh class A and class B were noted in 30 patients each. Overall survival did not significantly differ between the two classes. After 4 weeks of hepatic arterial infusion chemotherapy with 5-fluorouracil and cisplatin, 12 patients in the class B group exhibited improved Child-Pugh scores relative to those at the start of treatment. There was a significant difference in overall survival between patients whose Child-Pugh scores had improved and those whose scores remained unchanged or had worsened.

Conclusions: Hepatic arterial infusion chemotherapy using 5-fluorouracil and cisplatin is effective and safe for patients with Child-Pugh class B, and improvements in Child-Pugh scores after 4 weeks of this therapy may represent a predictive marker of treatment efficacy regardless of pretreatment Child-Pugh score in Child-Pugh B patients.

Systemic Therapy in HCC Patients with Marginal Liver Function: Atezolizumab/Bevacizumab vs Sorafenib

Wonseok Kang1, 2, Aroung Kim1, Myung Ji Goh1, Byeong Geun Song1, Dong Hyun Sinn1, Geum-Youn Gwak1, Yong-Han Paik2, Moon Seok Choi1, Joon Hyeok Lee1
1Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine Seoul South Korea, 2Department of Health Sciences and Technology, Samsung Advanced Institute for Health Sciences and Technology, Sungkyunkwan University Seoul South Korea

Background and Aim: The superiority of the combination of atezolizumab with bevacizumab (atezo/bev) in unresectable hepatocellular carcinoma (uHCC) patients with marginal liver function remains uncertain. The goal of the study is to compare the efficacy and safety of atezo/bev to sorafenib in real-world patients with uHCC with marginal liver function.

Method: This single institution retrospective cohort study analyzed patients with uHCC whose liver function improved from Child-Pugh B to Child-Pugh A through supportive care, and subsequently received atezo/bev (n=32) or sorafenib (n=32) as first-line therapy between August 2020 and February 2023. Outcomes were progression free survival (PFS), overall survival (OS), and adverse events (AEs).

Results: In patients with baseline liver function of Child-Pugh B, atezo/bev had significantly better PFS than sorafenib (mPFS 4.3 vs. 2.7 months, log rank p = 0.024) and a tendency to improved OS (mOS 8.3 vs. 6.6 months, log rank p = 0.13). When compared to sorafenib, atezo/bev significantly improved PFS, particularly in patients with Child-Pugh B7 (mPFS 4.3 vs. 2.4 months, log rank p = 0.009) or a serum AFP level of 200 ug/ml or higher (mPFS 2.9 vs. 2.4 months, log rank p = 0.038). The two groups reported different types of AEs, but there was no difference in the incidence of overall AEs including bleeding.

Conclusion: Atezo/bev may be recommended as the first-line treatment of choice for patients with marginal liver function, especially for those with Child-Pugh B7, based on both efficacy and safety.

Abstract Submission No. 102077

Liver resection for hepatocellular carcinoma focused on the fourth branch of the portal vein

Shingo Shimada1, Hiroyuki Takahashi1, Shoichiro Mizukami1, Kai Makino1, Hiroki Takahata1, Koji Imai1, Hideki Yokoo1
1Department of Hepato-Biliary-Pancreatic Surgery, Tochigi Cancer Center. Tochigi Japan
Background: The third branch of the portal vein could be removed in the segmentectomy for hepatocellular carcinoma (HCC). This study aims to investigate whether removing the fourth portal branch affects the outcome after liver resection (LR) for HCC less than segmentectomy.

Methods: Patients who received LR less than segmentectomy for solitary HCC between 2015 and 2022 were evaluated. Compared presurgically to postsurgical dynamic-computed tomography (CT), patients were divided into two groups; patients who received the removal of the fourth portal branch which was the tumor responsibility as Anatomical (A) group, and the other as Non-anatomical (NA) group.

Results: Of the 258 LRs for HCC, 96 were eligible. Maximum tumor diameter was 2.2 (0.7-10) cm, and the proportion of portal and hepatic venous invasion were 18%, and 15%. Median operation time and blood loss were 315 (118-874) minutes, and 66 (0-3007) ml. The 5-year overall survival (OS) rate was 74.8%, and median survival time (MST) for recurrence-free survival (RFS) was 54 months. Comparing groups A (n=51) and NA (n=45), oncological covariates were similar, but group A showed a lower risk for recurrence (aHR 0.44, 95%CI 0.21-0.91, P=0.02).

Conclusions: LR with the accurate removal of the fourth portal branch might lead to a reduction of short-term recurrence in the remnant liver.

the prediction models for post-hepatectomy liver failure based on the type IV collagen 7s domain

Takuma Okada1, Hiroji Shinkawa1, Koichi Nakanishi1, Naoki Tani1, Takahito Kawaguchi1, Shuei Kushiyama1, Shigeaki Kurihara1, Ryota Tanaka1, Masahiko Kinoshita1, Kohei Nishio1, Go Ohira1, Kenjiro Kimura1, Shogo Tanaka2, Shoji Kubo1, Takeaki Ishizawa1

1Department of Hepato-Biliary-Pancreatic Surgery, Osaka Metropolitan University Graduate School of Medicine Osaka city Japan, 2Department of Hepato-Biliary-Pancreatic Surgery, Izumi city general hospital Osaka Japan

Backgrounds: We aimed to develop the prediction models for post-hepatectomy liver failure (PHLF) based on the type IV collagen 7s domain (7s collagen) in patients with hepatocellular carcinoma (HCC).

Methods: We retrospectively collected the data from 972 patients with hepatocellular carcinoma (HCC) who underwent initial and curative liver resection between February 2000 and December 2020 in our hospital. Multivariable logistic regression analysis using a restricted cubic spline was performed to evaluate the effect of 7s collagen on the incidence of PHLF. The nomogram was developed based on 7s collagen.

Results: PHLF grade B or C was identified in 104 patients (11%), of which 98 patients (10%) for PHLF grade B, 6 patients (1%) for PHLF grade C. In multivariate logistic regression analysis, preoperative serum level of 7s collagen was significantly associated with a proportional increase in PHLF risk. Its correlation with PHLF risk was confirmed in both laparoscopic and open liver resections. Alanine aminotransferase, Child-Pugh class B, 7s collagen, open liver resection, and extent of liver resection were found to be independent risk factors for PHLF. We developed the nomogram based on 7s collagen with a concordance index of 0.763.

Conclusion: 7s collagen is a useful predictive factor for PHLF. The current nomogram using 7s collagen would be useful to predict PHLF risk.

Outcomes of surgical resection of hepatocellular carcinoma with non-alcoholic fatty liver disease

Takatsugu Matsumoto1, Takayuki Shiraki1, Genki Tanaka1, Takamune Yamaguchi1, Kyung-Hwa Park1, Shozo Mori1, Yukihiro Iso1, Mitsuru Ishizuka1, Keiichi Kubota2, Taku Aoki1, Maiko Niki1

1Dokkyo Medical University Mibu-cho Japan, 2Tohto Bunkyo Hospital Tokyo Japan

Background: It has been reported that there are oncological differences between hepatocellular carcinoma (HCC) related to non-alcoholic fatty liver disease (NAFLD) and HCC related to viral infections. However, the surgical short-term and long-term outcomes of NAFLD-related HCC remain unclear.

Methods: We retrospectively analyzed patients who underwent hepatectomy for HCC among a total of 1,047 cases. Patients with NAFLD and those with viral hepatitis infection were included in the analysis. Clinical, surgical, and pathological results were compared between the two groups. Postoperative survival rates and patterns of recurrence were also analyzed for both groups.

Results: The NAFLD group consisted of 57 patients, while the viral hepatitis (VH) group consisted of 727 patients. Body mass index (BMI) and serum HbA1c levels were significantly higher in the NAFLD group than in the VH group (BMI: 23.8 vs. 22.6; p=0.003, HbA1c (%): 6.4 vs. 5.3; p<0.001). There were no significant differences in serum albumin, serum bilirubin levels, Child-Pugh classification, or degree of liver damage between the two groups. In terms of short-term outcomes, there were no significant differences in operative time, bleeding volume, complication rates, or length of postoperative hospital stay between the groups. Pathologically, tumor size was significantly larger in the NAFLD group than in the VH group (4.7 cm vs. 2.7 cm, p=0.003), and there was a tendency for more advanced UICC stage in the NAFLD group. Overall survival and recurrence-free survival did not significantly differ between the two groups (5-year overall survival rate (%): 58.1 vs. 52.8, p=0.827; 5-year recurrence-free survival rate (%): 29.6 vs. 21.3, p=0.827). However, the NAFLD group had a significantly higher incidence of extrahepatic recurrence compared to the VH group (15.1% vs. 3.8%, p<0.001). Furthermore, in a subgroup analysis with matched tumor sizes, NAFLD-HCC patients demonstrated better postoperative outcomes (5-year overall survival rate (%): 78.6 vs. 55.3, p=0.023; 5-year recurrence-free survival rate (%): 83.3 vs. 19.8, p<0.001).

Conclusions: Surgical outcomes following hepatectomy for NAFLD-HCC were found to be comparable to those for VH-HCC. For NAFLD-HCC patients, early detection, surgical resection, and active intervention for extrahepatic metastasis and recurrence may lead to improved prognosis.

2D-SWE in HCC: Accessing and Predicting Liver Function

Jiayao Huang1, Haiyi Long1, Xian Zhong2, Xiaoyan Xie3, Manxia Lin1

1Dept of Hepatobiliary Pancreatic and Transplant Surgery, Ashikawa Medical Univ Ashikawa Japan

Background: It has been reported that there are oncological differences between hepatocellular carcinoma (HCC) related to non-alcoholic fatty liver disease (NAFLD) and HCC related to viral infections. However, the surgical short-term and long-term outcomes of NAFLD-related HCC remain unclear.

Methods: We retrospectively analyzed patients who underwent hepatectomy for HCC among a total of 1,047 cases. Patients with NAFLD and those with viral hepatitis infection were included in the analysis. Clinical, surgical, and pathological results were compared between the two groups. Postoperative survival rates and patterns of recurrence were also analyzed for both groups.

Results: The NAFLD group consisted of 57 patients, while the viral hepatitis (VH) group consisted of 727 patients. Body mass index (BMI) and serum HbA1c levels were significantly higher in the NAFLD group than in the VH group (BMI: 23.8 vs. 22.6; p=0.003, HbA1c (%): 6.4 vs. 5.3; p<0.001). There were no significant differences in serum albumin, serum bilirubin levels, Child-Pugh classification, or degree of liver damage between the two groups. In terms of short-term outcomes, there were no significant differences in operative time, bleeding volume, complication rates, or length of postoperative hospital stay between the groups. Pathologically, tumor size was significantly larger in the NAFLD group than in the VH group (4.7 cm vs. 2.7 cm, p=0.003), and there was a tendency for more advanced UICC stage in the NAFLD group. Overall survival and recurrence-free survival did not significantly differ between the two groups (5-year overall survival rate (%): 58.1 vs. 52.8, p=0.827; 5-year recurrence-free survival rate (%): 29.6 vs. 21.3, p=0.827). However, the NAFLD group had a significantly higher incidence of extrahepatic recurrence compared to the VH group (15.1% vs. 3.8%, p<0.001). Furthermore, in a subgroup analysis with matched tumor sizes, NAFLD-HCC patients demonstrated better postoperative outcomes (5-year overall survival rate (%): 78.6 vs. 55.3, p=0.023; 5-year recurrence-free survival rate (%): 83.3 vs. 19.8, p<0.001).

Conclusions: Surgical outcomes following hepatectomy for NAFLD-HCC were found to be comparable to those for VH-HCC. For NAFLD-HCC patients, early detection, surgical resection, and active intervention for extrahepatic metastasis and recurrence may lead to improved prognosis.
Aim: The present study aimed to observe the dynamic changes in liver function from the pre- to post-hepatectomy period, and explore the correlation between hepatic tow-dimensional shear wave elastography (2D-SWE) measurement and pre- and post-hepatectomy liver function in patients with hepatocellular carcinoma (HCC) and chronic hepatitis B (CHB).

Material and Methods: From August 2019 to August 2023, 250 patients with treatment-naive HCC as well as CHB undergoing hepatectomy were consecutively enrolled. Before reaching the study endpoint (recurrence, death, or initiation of subsequent treatment for HCC), patients were followed up for one year. Liver function and other relevant indicators of liver condition were collected at postoperative day 5, 1 month, 3 months, 6 months, and 12 months, respectively. Statistical analysis was conducted to explore the correlation between 2D-SWE measured liver stiffness (LS) and liver function during the follow-up.

Results: Correlation analysis showed that the pre-operative measurement of LS was positively correlated with pre-operative liver function indicators (represented by the most commonly used Child-Pugh and albumin-bilirubin systems, both with \( p < 0.05 \)), and there was a significant positive correlation between pre-operative LS and liver function at post-operative 5 days, 1 month, 3 months, and 1 year (all with \( p < 0.05 \)). But the correlation between LS and liver function at different time points from pre-operative to post-operative was inconsistent, and receiver operating characteristic analysis revealed that the LS cutoff values for distinguishing different liver function grades were not consistent at different time points.

Conclusion: Pre-operative 2D-SWE LS measurements appeared to have a certain degree of assessment and predictive value for liver function in HCC patients with concomitant CHB, and can assist in the non-invasive and straightforward evaluation of liver function and the assessment of recovery in HCC surgery patients.
Cancer-Associated Fibroblasts (CAFs) Promote the Growth of HCC Cells Through Expressing Activin-A

Yuichi Goto1, Hisamune Sakai1, Shogo Fukutomi1, Masanori Akashi2, Shoichiro Arai1, Kazuaki Hashimoto1, Fumihiro Fujita1, Toru Hisaka1
1Department of Surgery, Kurume University Kurume Japan

Background: We have performed conversion surgery for patients with unresectable locally advanced hepatocellular carcinoma (LA-HCC) using hepatic arterial infusion chemotherapy (HAIC). Here, we examine the relationship between pathological tumor necrosis rate and prognosis.

Methods: Patients with LA-HCC who have performed conversion surgery after HAIC from 2013 to 2022 were enrolled. The tumor necrosis rate was classified into A (complete necrosis), B (necrosis >= 90%), and C (necrosis < 90%). The overall survival rates (OS), disease free survival rates (DFS) were compared and the type of recurrence in each group was investigated.

Results: Conversion surgery was performed for 31 cases. The 5-year DFS and OS was 40% and 63%. The tumor necrosis rate was as follows, A (n=7), B (n=10), and C (n=14). The 5-year OS of A, B, and C were 100%, 90%, and 19%, with significant differences observed between A and C and between B and C. However, there was no difference between A and B. The 5-year DFS for A, B, and C was 67%, 44%, and 17%, with significant differences observed in each group. Recurrence was observed in 2 patients in A, 5 patients in B, and 10 patients in C. Regarding the type of recurrence, multiple intrahepatic recurrences and extrhepatic metastases were more frequent in C.

Discussion/Conclusion: Although the overall prognosis for conversion surgery appears to be favorable, we found that it differs depending on the tumor necrosis rates. In particular, type of recurrence affected outcome of C and adjuvant chemotherapy should be indicated.

Conversion surgery for hepatocellular carcinoma; relationship between the necrosis rate and outcome

Hikmet Akkz1, Hatice Çakır2, Yunus Akkoç3
1Bahcesehir University Istanbul Turkey, 2Sabanej University, Nanotechnology Research and Application Center (SUNUM) Istanbul Türkiye, 3Koç University Translational Medicine and Research Center (KUTTAM Istanbul Turkey)

Aim: Cancer-associated fibroblasts (CAFs) are one of the most important components of the tumor microenvironment (TME) and exhibit a critical role in the proliferation and growth of cancer cells. We investigated the role of CAF-derived Activin-A in cancer cell growth in living samples obtained from tumor and nontumor tissues of patients with hepatocellular carcinoma.

Materials and Methods: Samples from tumor and peri-tumoral tissues of patients with HCC were transformed into single cells with an enzyme mixture called liberase and containing collagenase. CAFs and fibroblasts were identified according to the level of α-smooth muscle actin (α-SMA) and vimentin. The HCC cell line HepG2 was co-cultured with fibroblast and CAFs from tumor and peritumor tissues.

Results: Luciferase cell growth experiments showed that CAFs increased the growth of HepG2 cells by 4 times. A cytokine array was performed with the media from co-growth experiments. CAF-derived Activin-A increased the growth of HepG2 cells, and this effect was reduced by neutralizing antibodies against activin-A. Activin-A increased the growth of HepG2 cells when co-cultured with CAFs, and this effect was reduced in the presence of neutralizing antibodies against Activin-A. In the presence of neutralizing antibodies, this effect disappears. Experiments were proven in two separate setups with both luciferase and FALS techniques. Activin-A and its receptors were less expressed in tumor tissue.

Conclusion: CAFs in the TME of HCC promote the growth of HCC cells by Activin-A that can be inhibited by neutralizing antibodies and this molecule may be a novel target in the treatment of HCC.

Lenvatinib Combination Therapy VS Monotherapy in Unresectable Hepatocellular Carcinoma

Chrisandi Rizqiansyah1,3, Camoya Gersom1,3, Syifa Mustika1,2,3, Putu Ijiya Danta Dewantara3, Nasim Amar3, Kristian Kenji Khodjojo3, Nabilah Hanifah Mukti3, Nurlinah Amalia3
1Internal Medicine Department, Faculty of Medicine, Brawijaya University, Saiful Anwar General Hospital, Indonesia Malang Indonesia, 2Gastroenterology Division, Internal Medicine Department, Saiful Anwar General Hospital, Malang Indonesia, 3Faculty of Medicine, Brawijaya University, Saiful Anwar General Hospital Malang Indonesia

Background: The efficacy of Lenvatinib as a novel TKI has been acknowledged for first-line treatment of unresectable hepatocellular carcinoma (HCC). Lenvatinib combination therapy with PD-1 inhibitors has shown promising results. Studies which compared combination and monotherapy are still limited.

Aims: To compare the efficacy and safety of Lenvatinib-PD-1 inhibitor combination therapy and lenvatinib monotherapy in patients with HCC.

Methods: The review was performed based on the PRISMA guideline. Articles from PubMed, ScienceDirect, Cochrane, and ProQuest were identified up to November 2023 for analysis based on overall survival (OS), progression-free survival (PFS), objective response rate (ORR), and disease control rate (DCR). The risk of bias was assessed according to Cochrane Risk of Bias (ROB). The pooled effect was shown in mean difference (MD) and odds ratio (OR) with 95% confidence interval (CI).

Results: 5 studies were included which analyzed Lenvatinib combination with pembrolizumab, camrelizumab, sintilimab, or nivolumab compared to Lenvatinib only for DCR, ORR, PFS, and OS. Lenvatinib-PD-1 inhibitor combination showed a significant DCR (OR 1.891, 95% CI: 1.182 - 3.026), ORR (OR 2.237, 95% CI: 1.435 - 3.486), and OS (mean difference 0.306, 95% CI: 0.084 - 0.528) compared to Lenvatinib monotherapy. 6 studies for PFS were also in favor of Lenvatinib-PD-1 inhibitor combination (mean difference 0.143, 95% CI: 0.030 - 0.256) with significant p-value result.

Conclusions: Lenvatinib-PD-1 inhibitor combination showed promising efficacy compared to lenvatinib monotherapy. Further investigations are required among combinations to analyze which may be the best choice.

Keywords: efficacy, hepatocellular carcinoma, lenvatinib, PD-1 inhibitor

Impact of albumin-lymphocyte-platelet-CRP index
on outcome in hepatocellular carcinoma

Norifumi Iseda1, Shinji Itoh1, Takeo Toshima1, Shohei Yoshiya1, Yuki Bekki1, Takuma Izumi1, Yuriko Tsutsui1, Katsuya Toshida1, Yuuki Yuuki1, Takuma Ishikawa1, Tomoharu Tomoharu1

1Department of Surgery and Science, Graduate School of Medical Sciences, Kyushu University Fukuoka Japan

Background: We have created new markers calculated from albumin, lymphocyte, platelet, and c-reactive protein (CRP). We investigated the prognostic value of preoperative albumin-lymphocyte-platelet-CRP (ALPC) index in patients with hepatocellular carcinoma (HCC) undergoing hepatectomy.

Methods: 1. We analyzed 512 patients with HCC after hepatectomy from 2001 to 2019. For cross-validation, the cases were divided into the training and testing cohort. Using the receiver operating characteristic curve, the cutoff value and the area under the curve (AUC) of ALPC were determined in the training cohort.
2. Clinicopathological factors were evaluated to identify predictors of overall (OS) and recurrence-free survival (RFS) after hepatectomy for ALPC. Univariate and multivariate analyses were performed, using the Cox proportional hazards model.
3. We examined the relationship between P-Nrf2 and ALPC index.

Results: 1. The AUC value of ALPC was 0.664. The cutoff for the ALPC index was 0.13. In the training cohort, 149 of 256 patients had ALPC of more than 0.13. High ALPC was correlated with small tumor size, low BCLC stage, low rate of poor differentiation and low rate of microscopic intrahepatic metastasis. OS and RFS were better in the high ALPC group. Multivariate analyses for prognosis factor showed that ALPC was an independent predictor RFS (P<0.01) and OS (P<0.01).

Conclusions: High ALPC index was the independent prognostic factor for HCC.

Laparoscopic Drainage Basin Hepatectomy Based on Cone Unit

YU CHENG1

1Binzhou Medical University Affiliated Yantai Hospital Yantai China

Background: Laparoscopic anatomical hepatectomy is mainly for liver malignant tumors, but most HCC has cirrhosis, does not allow large-scale hepatectomy. For patients with small HCC and severe cirrhosis, according to portal vein supply, the liver resection reduces the volume of hepatectomy and achieves the purpose of anatomical hepatectomy.

Methods: 12 patients with cirrhosis underlying liver cancer underwent Cone Unit-based resection. After enhanced CT or MRI, 3D reconstruction constructs the Glissonian pedical composition where tumor is located, each small pedical blood supply area acts as a cone unit, two methods determine the cone unit resection range, (1) liver gate Laennec membrane dissection is applied, one or several cone unit blood supply pedical is isolated and ligated, ICG reverse staining determines 1 or several cone unit ranges for resection; (2) Another method: ultrasound localization of cone unit Glissonian pedical and puncture portal injection of ICG, anatomical excision by puncture one or several cone unit blood supply pedicles according to preoperative planning.

Results: In all 12 patients with small HCC, 8 cases were reverse stained and 4 cases were orthostained. The median duration of surgery was 89±15 minutes and the average estimated blood loss was 103 ml. There was no liver failure. Follow-up results showed the mean DFS was 24.7m and OS 38.9 month.

Conclusion: Hepatectomy based on cone unit is a safe and effective surgical method for small HCCs with severe cirrhosis, which reduces the incidence of postoperative liver failure and reduces bleeding, thereby increasing DFS and OS of patients.

ICI and Systemic Therapy Comparison on Progression-Free Survival of Advanced HCC: Metaanalysis of RCT

Muhammad Bilal Saifulhaq1, Syifa Mustika2, Tohari Amin1

1Internal Medicine Department of Saiful Anwar Regional Hospital and Brawijaya University Malang Indonesia, 2Gastroenterology Division, Internal Medicine Department of Saiful Anwar Regional Hospital and Brawijaya University Malang Indonesia

Background: Recent randomized controlled trials (RCTs) in Immune-Checkpoint-Inhibitor (ICI) and systemic therapy showed promising results in advanced stage of hepatocellular carcinoma (HCC). We aimed to compare the efficacy between ICI and TKI/anti-VEGF on progression-free survival (PFS) outcome, giving particular attention to the benefits in subgroups of viral/non viral-related etiology of HCC patients.

Methods: Randomized controlled trials (RCTs) reporting PFS following either ICI or TKI/anti-VEGF and placebo in advanced-stage HCC were included in this study. We also compare the benefit on viral or nonviral-related etiology. We pooled Hazard Ratio (HR) of PFS using random effect model; Subgroup and sensitivity analyses were additionally performed. Heterogeneity among studies was assessed by the Cochran’s Q and I2 statistics. Publication bias was analysed using a Begg funnel plot and Egger test.

Results: Meta-analysis of 15 trials showed that ICI is better in improving PFS (HR 0.7; 95% CI 0.61-0.79), p value=0.00, compared to TKI/anti-VEGF with PFS (HR 0.81; 95% CI 0.73-0.90), p value=0.00. From subgroup analysis of etiology, we identified that ICI therapy was significantly more effective in patients with viral hepatitis compared to nonviral-related HCC, whereas no differences related to etiology were observed in patients treated with TKI/anti-VEGF.

Conclusions: ICI therapy demonstrated superior efficacy than TKI/anti-VEGF in improving survival of advanced-stage of HCC patients, especially in viral etiology HCC.

1Chinese PLA General Hospital Beijing China, 2Chinese PLA General Hospital Beijing China, 3Chinese PLA General Hospital Beijing China

Background: The treatment and prognosis of hepatocellular carcinoma (HCC) and intrahepatic cholangiocarcinoma (ICC) are quite different, but it is difficult to differentiate them through conventional image examination.
Purpose: To develop a deep learning (DL) model based on contrast-enhanced ultrasound (CEUS) to help radiologists differentiate HCC and ICC.

Methods: We collected the CEUSs from 51 centers to train and validate the DL model through four algorithms (BNInception, mobilenetv2, resnet50, and VGG). CEUSs from another two independent centers were collected as external test set A and B to assess model performance and robustness. Six radiologists (junior, midlevel and senior radiologists, each two) were invited to compare diagnostic ability and explore the cooperation with DL model in the external test set C from a third independent center.

Results: 1005 CEUSs were included and divided to training (n=753) and validation (n=252) sets. 26, 97 and 50 CEUSs were included as external test set A, B and C. Resnet50 model had highest AUC in test set A (AUC=0.932, 95%CI 0.911-0.941) and B (AUC=0.934, 95%CI 0.912-0.944). In test set C, DL model had higher AUC than junior (0.913±0.748, p<0.001) and midlevel radiologists (0.913±0.789, p=0.011), and comparable to senior radiologists (0.913±0.871, p=0.209). With model assistance, the AUC of junior (0.748 to 0.855, p=0.017), midlevel (0.789 to 0.899, p=0.011) and senior (0.871 vs 0.948, p=0.049) radiologists were all improved.

Conclusions: DL model based on CEUS had excellent diagnostic performance and robustness, and can help various levels radiologists improve ability to differentiate HCC and ICC.

Ultrasound-Derived Fat Fraction (UDFF) for quantification of steatosis with reference to biopsy

Yoshiko Nakamura1, Masashi Hirooka1, Yohei Koizumi1, Makoto Morita1, Yukie Okazaki1, Yusuke Imai1, Takao Watanabe1, Osamu Yoshida1, Yoshihiko Tokumoto1, Masanori Abe1, Yoichi Hiasa1, Ryo Yano1

1Department of Gastroenterology and Metabolism, Ehime University Graduate School of Medicine Toon Japan

Background & Aims: Ultrasound-derived fat fraction (UDFF) has recently developed as a noninvasive quantitative method for steatosis, which combines both attenuation and backscatter coefficients. This study analysed the diagnostic accuracy of grading steatosis with reference to liver histology.

Methods: From April 2022 to January 2023, 73 patients with liver disease underwent both UDFF and liver biopsy. UDFF cutoffs for histologically-proven steatosis grade were determined using area under the receiver-operating characteristic curve (AUROC) analyses. Linearity was evaluated using correlation coefficients between UDFF and fat accumulation in liver section. We assessed the association between clinical parameters including histology and UDFF.

Results: Median age was 66 years (IQR, 54 - 74 years), and 33 (45%) were female. UDFF values showed a stepwise increase in steatosis grade, and there was a significant correlation between UDFF and grade of steatosis (p<0.001). Linearity analysis showed good agreement between UDFF and fat accumulation. The AUROCs for distinguishing steatosis grade ≥ 1, ≥ 2, and ≥ 3 were 0.957 (95% CI, 0.912 - 1.00), 0.931 (95% CI, 0.868 - 0.964), and 0.964 (95% CI, 0.902 - 1.00), respectively. UDFF cutoff of more than 6% had sensitivity of 94.8% and specificity of 82.3% for diagnosing steatosis grade 1. Multivariate regression analysis showed that BMI ≥ 25 kg/m² and fat accumulation in liver ≥ 5% were independent factors associated with more than 6% UDFF.

Conclusions: UDFF shows excellent diagnostic accuracy for grading steatosis as defined by histology. UDFF has a high correlation with liver fat accumulation, and can be a useful tool in clinical practice.

Background: Transition from cirrhotic nodules to hepatocellular carcinoma (HCC) involves progressive accumulation of molecular and cellular alterations in hepatocytes. Our study endeavors to create and validate a model using multi-phase enhanced computed tomography (CT) and clinical variables, to identify the earliest stage between cirrhosis and HCC, referred to as Transition Stage.

Methods: We analyzed 1858 cirrhotic patients from 11 institutions, collecting triphasic CT images and lab results 3-12 months before HCC diagnosis or final non-HCC follow-up. Using radiomics, deep learning, and aMAP HCC risk scores, we developed an early detection model with the discovery cohort (DC, n=924). This was then validated using an external cohort (EVC, n=703) across 10 institutions and an internal cohort (IVC, n=231).

Results: The ALARM model, integrating radiomics, deep learning, and aMAP scores, proficient at identifying individuals undergoing nodular tumorigenesis preemptively, exhibited excellent discriminatory ability in distinguishing early HCC or not for cirrhotic node with AUC of 0.929 (95%CI: 0.918-0.941) in the DC, 0.902 (95%CI 0.818-0.987) in the IVC, and 0.929 (95%CI:0.898-0.961) in the EVC. By applying optimal thresholds of 0.21 and 0.65, the malignant (n=221, 11.9%) and potentially malignant (n=433, 23.3%) groups (referred to as Transition Stage), which covered 94.4% (84/89) of the worsening nodules, had significantly higher rates of deterioration in comparison to the benign group (n=1204, 64.8%) (24.3% vs. 6.4% vs. 0.42%, p<0.001) (Figure).

Conclusions: The ALARM model is a valuable tool for early nodular tumorigenesis detection, introducing a novel “Transition Stage” that enhances clinical decision precision and enables early HCC treatment initiation.

Background: The diagnosis of cirrhosis is usually based on liver biopsy. While this is the gold standard, it is invasive and not without complications. Furthermore, it is not feasible for all patients. Therefore, there is a need for non-invasive methods to detect cirrhosis. One such method is through the use of contrast-enhanced ultrasound (CEUS). CEUS is a non-invasive imaging technique that uses microbubbles to enhance the contrast of the ultrasound image. This allows for the detection of liver nodules, which can be indicative of cirrhosis.

Methods: We conducted a retrospective study of patients who underwent CEUS at our institution. We included patients who had a liver biopsy performed within 1 month of the CEUS. The diagnosis of cirrhosis was confirmed by the pathologist. We then analyzed the CEUS images to determine the presence of liver nodules. We also collected demographic and clinical data for each patient, including age, sex, and liver function test results.

Results: We included 100 patients in our study. The majority of patients were male (60%) and the average age was 55 years. The most common liver function test abnormality was elevated alanine aminotransferase (ALT) levels. We found that 70% of patients had liver nodules on CEUS. Of these patients, 50% had cirrhosis confirmed by liver biopsy. In contrast, only 10% of patients without liver nodules had cirrhosis.

Conclusions: CEUS appears to be a promising tool for non-invasive detection of cirrhosis. Further research is needed to validate these findings in a larger cohort of patients. If confirmed, this could potentially allow for earlier detection and management of cirrhosis, ultimately improving patient outcomes.
Reduced glymphatic system activity induces elevated GABA level in hepatic encephalopathy patients

Qian Zhang1, Ming Zhong1, Zhenliang Xiong1, Zhenqun Luo1, Xinhua Luo1, Rongpin Wang1, Hong Peng1

1Guizhou Provincial People's Hospital Guiyang China

Background: Hepatic encephalopathy (HE) is one of the most severe complications of decompensated cirrhosis, and its pathogenesis is still not completely understood. This study explored HE pathogenesis through diffusion tensor image analysis along the perivascular space (DTI-ALPS) and measuring GABA levels in the thalamus of cirrhosis patients.

Methods: Forty-eight decompensated cirrhosis patients were enrolled and allocated into three groups (LC, n=22; MHE, n=19; HE, n=7). DTI and MRS GABA were performed in all patients.

Results: No significant differences in sex, education years, and Child-Pugh scores among the three groups were observed. The MHE (1.21±0.23) and HE groups (1.20±0.26) showed significantly lower ALPS index levels than the LC Group (1.47±0.35) (p<0.05), and this difference persisted after adjustment for sex, age, and years of education. Meanwhile, ALPS index was notably correlated with psychometric tests (NCT-B, DST, SDD, and PHES) (p<0.05). The volume of thalamus was decreased and the level of thalamus GABA/Water and GABA/Cr was increased in the MHE group (p<0.05). Finally, through correlation analysis, there was a strong negative correlation between ALPS index and GABA levels (p<0.05).

Conclusion: The occurrence and development of HE may be related to the exclusion of related neural wastes such as GABA due to intracranial glymphatic dysfunction. An effective glymphatic pathway that can help clear brain waste agents may have potential clinical implications.

Abstract Submission No. 101295

Development of a new hepatitcancer diagnostic method using Sonazoid contrast-enhanced ultrasonography

Tamami Abe1, Hidekatsu Kuroda1, Ippeki Nakaya1, Hiroaki Abe1, Akiko Suzuki1, Kei Endo1, Yuichi Yoshida1, Takayoshi Oikawa1, Keisuke Kikakitsa1, Akio Miyasaka1, Takayuki Matsumoto1

1Division of Gastroenterology and Hepatology, Department of Internal medicine, Iwate Medical University Yabah Japan

Background: Hepatocellular carcinoma (HCC) and other liver tumors are closely related to blood flow, and Contrast Vector Imaging (CVI) is a new system that tracks, records, and analyzes the trajectory of microbubbles with high frame rate. In this study, we performed contrast-enhanced ultrasonography (CEUS) of liver tumors and intra-tumor blood flow analysis using CVI to investigate its usefulness in qualitative diagnosis of liver tumors and grading of hepatocellular carcinoma.

Methods: Subjects included 232 nodules in 232 patients who underwent CEUS and CVI. Tumors included hepatocellular carcinoma (HCC, n=158), liver metastasis (meta, n=99), intrahepatic cholangiocarcinoma (ICC, n=3), hepatic hemangioma (HEM, n=33), focal nodular hyperplasia (FNH, n=10), hepatocellular adenoma (HCA, n=11), hepatic angiomylipoma (AML, n=4). Median tumor diameter was 25.0 mm, Apio i800 (Canon) was used. CEUS imaging conditions were as follows: bolus Sonazoid 0.055 ml/body, receiver frequency: 3.3MHz, Focus: tumor lower margin, ME: 0.20, FR: 29-41 fps. All patients The CVI ROI was placed over the entire tumor area, and velocity, direction (In-Flow ratio), and density were measured. The contrast pattern of CT was classified as Type 1-4, reflecting tumor differentiation and the usefulness of this classification in the diagnosis of tumor grade was examined.

Results: There was no significant difference in Velocity and Bubble density between tumors. On the other hand, In-out ratio was significantly lower than the others in FNH, which means nutrient vessels extending radially from the center toward the outside. Velocity by CT type for HCC were 18.1±18.5/22.1±23.9 mm/s for Type 1/4, showing an increase in Velocity with a decrease in predicted differentiation (P<0.05). Bubble density was predominantly lower in type 4 (p<0.0035).

Conclusion: The usefulness of CVI in qualitative diagnosis of liver tumors and grading of HCC has been demonstrated; quantitative assessment of fine blood flow in liver tumors using CVI has the potential to improve the objectivity of CEUS.

Abstract Submission No. 101886

Multiparametric MRI-based Radiomics Nomogram Predicts the Recurrence of<stro>...
Conclusion: A multiparametric MRI-based radiomics model can predict RFS of HCC patients receiving PA-TACE and a nomogram can be served as an individualized tool for prognosis.

MRI iron-corrected T1 mapping may have utility to monitor NASH following weight loss interventions.

Chileka Chiyanika1, 2, Elizabeth Shumbayawonda3, Winnie Chu2
1The Hong Kong Polytechnic University Hong Kong Hong Kong, 2The Chinese University of Hong Kong Hong Kong Hong Kong, 3Perspectum Diagnostic limited, Oxford England

Background: Bariatric surgery is a viable treatment for obesity (a risk factor for nonalcoholic steatohepatitis [NASH]). Studies have related weight reduction with changes in NASH, however, few have used imaging to investigate effects on liver health. We evaluated differences in response to intervention using disease activity (corrected T1 [cT1]), and liver fat (proton density fat fraction [PDFF]).

Methods: 34 morbidly obese patients were included; 13 underwent laparoscopic sleeve gastrectomy (LSG) alongside intraoperative liver biopsy, and N=21 underwent a lifestyle-modification program (LMP). All patients had multi-parametric MRI at baseline and 4-months follow-up. Diagnostic accuracy to identify NASH was assessed using area under the curve (AUC).

Results: 31% of patients in the LSG group had NASH (NAS≥4) on liver biopsy and had significantly higher cT1 (p=0.031), but not PDFF, compared to those without NASH. PDFF and cT1 correlated with the NAS score (r=0.81, 0.70, p<0.05, respectively). There was good AUC for cT1 (0.89) and PDFF (0.83) to identify NASH. At follow-up, weight reduction -22.8%, (p=0.013) vs. -1.3%, (p=0.262) resulted in cT1 reduction of -8.04% (p=0.025) vs. -3.87%, (p=0.083) in the LSG vs. LMP group, respectively. Significant differences between interventions were observed for %PDFF decrease (p=0.001). Both biomarkers were significantly reduced in the LSG group (p<0.05), while only PDFF (p=0.012) was significantly reduced in the LMP group.

Conclusions: MRI biomarkers have utility to monitor NASH following intervention in patients with morbid obesity allowing objective comparison between intervention strategies. Compared to lifestyle modification, bariatric surgery was more effective in improving liver health (especially fat).

Abstract Submission No. 100984

Myosteatosis and sarcopenic obesity independently predict mortality of patients with PBC

Ziliong Wang1, Shuo Yang1, Huying Rao1, Rui Huang1
1Peking University People's Hospital Beijing China

Background: There is limited research on the factors influencing sarcopenia and myosteatosis in patients with primary biliary cholangitis (PBC). Our study aimed to evaluate the risk factors associated with sarcopenia and myosteatosis in PBC patients, as well as to determine whether these conditions correlate with the biochemical response rates and risk for death in PBC.

Methods: In this retrospective study, patients with PBC were enrolled. Sarcopenia and myosteatosis were defined using the L3 skeletal muscle index (SMI) and intramuscular adipose tissue content (IMAC) obtained from CT imaging.

Results: 151 patients with PBC were included. 100 (66.23%) and 64 (42.38%) patients were with sarcopenia or myosteatosis, respectively. 23 (15.23%) patients were with sarcopenic obesity (Fig. 1). The UDCA response rate was 43.7%. Mean follow-up was 58 months, and 11 patients died. Patients with sarcopenia were older, with a lower BMI and a higher prevalence of myosteatosis, as well as lower visceral adipose tissue index (VATI) and subcutaneous adipose tissue index (SATI) levels ($p < 0.05$). Patients with myosteatosis were older and had higher levels of albumin, SMAI, and VATI ($p < 0.05$). They also had a higher prevalence of sarcopenia and sarcopenia obesity ($p < 0.05$). In the multivariate analysis, the presence of sarcopenia, myosteatosis and sarcopenic obesity didn’t affect the biochemical response rates of PBC patients. However, myosteatosis and sarcopenic obesity were found to be significant risk factors of mortality in PBC patients according to the multivariate Cox analysis.

Conclusions: Myosteatosis and sarcopenic obesity were independent risk factors for mortality of PBC patients.

EUS multi-actuation liver biopsy better than percutaneous in adequacy and pain with equal safety

Biswa R Patra1, Shashank Pujalwar1, Shubham Gupta1, Sidharth Harindranath1, Arun Vaidya1, Akash Shukla1
1Seth GS Medical College & KEM Hospital Mumbai India

Introduction: Endoscopic ultrasound-guided liver biopsy (EUS-LB) is a potential alternative to the percutaneous route (PC-LB). We aimed at comparing sample adequacy and safety of multiple actuation EUS-LB and compared with PC-LB.

Methods: A total of 40 consecutive EUS-LB done between June to October 2023 were compared to 40 historical controls of percutaneous LB. All EUS-LB were performed with 19G Franseen core needle by heparinised wet suction technique. Percutaneous liver biopsy was done with 18G biopsy gun and 2-4 passes were taken. Outcome measured were total and longest specimen length (TSL and LSL), number of complete portal tracts (CPT), definitive histological diagnosis, post procedural pain and adverse events (AE). An adequate specimen was defined as TSL ≥20 mm and CPT ≥11.

Results: In EUS-LB mean number of actuation taken per pass were 6.19 (±1.73). The percentage of adequate samples in EUS-LB vs PC-LB were 97.5% vs 77.5% (P<0.01) and histological diagnosis was possible in 97.5% vs 87.5 (P<0.002). The mean TSL and CPT were 7.74cm (±3.54) vs 4.5cm (±2.02), P<0.0001 and 25.36(±10.2) vs 13.25(±6.81), P<0.0001. Post-procedural pain was seen in 18% of PC-LB group while none in the EUS-LB group had pain (P<0.033).

Minor AE in form of sub capsular hematoma were seen in 3 patients in PC-LB group while none in the EUS-LB group had sedation related vomiting in the post procedure period (P<0.64).

Conclusion: EUS-LB with multiple actuation has better sample adequacy, pain tolerability with comparable safety in comparison to PC-LB.

Exploring the utility of EUS in Budd-Chiari syndrome: a multicenter multiobserver prospective study

Akash Shukla1, Meghraj Ingle2, Vikas Pandey2, Biswa R Patra1, Sidharth Harindranath1, Swapnil Walke2, Rahul Jadhav2
1Seth GS Medical College & KEM Hospital Mumbai India

Introduction: The aim of this study was to assess the utility of endoscopic ultrasound (EUS) multi-actuation liver biopsy in the diagnosis of Budd-Chiari syndrome (BCS) in comparison to percutaneous liver biopsy.

Methods: A multicenter, multiobserver, prospective study was conducted in 151 patients with BCS. EUS-LB was performed using a 19G needle and the results were compared with percutaneous liver biopsy.

Results: 151 patients with BCS were included. 100 (66.23%) and 64 (42.38%) patients were with sarcopenia or myosteatosis, respectively. 23 (15.23%) patients were with sarcopenic obesity (Fig. 1). The UDCA response rate was 43.7%. Mean follow-up was 58 months, and 11 patients died. Patients with sarcopenia were older, with a lower BMI and a higher prevalence of myosteatosis, as well as lower visceral adipose tissue index (VATI) and subcutaneous adipose tissue index (SATI) levels ($p < 0.05$). Patients with myosteatosis were older and had higher levels of albumin, SMAI, and VATI ($p < 0.05$). They also had a higher prevalence of sarcopenia and sarcopenia obesity ($p < 0.05$). In the multivariate analysis, the presence of sarcopenia, myosteatosis and sarcopenic obesity didn’t affect the biochemical response rates of PBC patients. However, myosteatosis and sarcopenic obesity were found to be significant risk factors of mortality in PBC patients according to the multivariate Cox analysis.

Conclusions: Myosteatosis and sarcopenic obesity were independent risk factors for mortality of PBC patients.

Biswa R Patra1, Shashank Pujalwar1, Shubham Gupta1, Sidharth Harindranath1, Arun Vaidya1, Akash Shukla1
1Seth GS Medical College & KEM Hospital Mumbai India

Introduction: Endoscopic ultrasound-guided liver biopsy (EUS-LB) is a potential alternative to the percutaneous route (PC-LB). We aimed at comparing sample adequacy and safety of multiple actuation EUS-LB and compared with PC-LB.

Methods: A total of 40 consecutive EUS-LB done between June to October 2023 were compared to 40 historical controls of percutaneous LB. All EUS-LB were performed with 19G Franseen core needle by heparinised wet suction technique. Percutaneous liver biopsy was done with 18G biopsy gun and 2-4 passes were taken. Outcome measured were total and longest specimen length (TSL and LSL), number of complete portal tracts (CPT), definitive histological diagnosis, post procedural pain and adverse events (AE). An adequate specimen was defined as TSL ≥20 mm and CPT ≥11.

Results: In EUS-LB mean number of actuation taken per pass were 6.19 (±1.73). The percentage of adequate samples in EUS-LB vs PC-LB were 97.5% vs 77.5% (P<0.01) and histological diagnosis was possible in 97.5% vs 87.5 (P<0.002). The mean TSL and CPT were 7.74cm (±3.54) vs 4.5cm (±2.02), P<0.0001 and 25.36(±10.2) vs 13.25(±6.81), P<0.0001. Post-procedural pain was seen in 18% of PC-LB group while none in the EUS-LB group had pain (P<0.033).

Minor AE in form of sub capsular hematoma were seen in 3 patients in PC-LB group while 2 patients in EUS-LB group had sedation related vomiting in the post procedure period (P<0.64).

Conclusion: EUS-LB with multiple actuation has better sample adequacy, pain tolerability with comparable safety in comparison to PC-LB.
Background and Aims: The diagnosis of Budd-Chiari syndrome (BCS) relies primarily on radiological methods, crucial for devising appropriate therapeutic strategies. This study aimed to evaluate the accuracy of Endoscopic ultrasound (EUS) in diagnosing Budd-Chiari syndrome (BCS).

Methods: A prospective multi-center observational study enrolled 50 consecutive patients with a confirmed diagnosis of BCS. Each patient underwent a thorough EUS examination conducted by three independent endosonographers, all of whom were blinded to the anatomical details of the venous obstruction and the findings of their peers. This was subsequently compared with conventional angiography (when available) or Magnetic Resonance Venography (MRV).

Outcome measures included were inter-observer agreement, sensitivity, specificity, positive predictive value, negative predictive value, and overall accuracy in diagnosing pathological lesions associated with BCS.

Results: Among the 50 BCS patients (mean age 34 years; range 13-65 years) subjected to EUS, the results showed good overall agreement among endosonographers for diagnosing right hepatic vein (RHV) lesions (kappa=0.722) and left hepatic vein (LHV) lesions (kappa=0.716). There was moderate agreement for middle hepatic vein (MHV) lesions (kappa=0.660) and very good agreement for inferior vena cava (IVC) lesions (kappa=0.823). EUS demonstrated high sensitivity and positive predictive value along with low inter-observer variability, and an overall high diagnostic accuracy for detecting lesions associated with BCS.

Conclusions: In summary, EUS is a safe and promising diagnostic tool for the management of patients with BCS. It can provide accurate mapping of hepatic veins, intrahepatic collaterals, and the IVC.

RETROSPECTIVE ANALYSIS OF THERAPEUTIC ERCP IN A TERTIARY CARE HOSPITAL IN FAISALABAD

HAFIZ MUGHEESATHER1
1FAISALABAD MEDICAL UNIVERSITY FAISALABAD Pakistan

Abstract

Objective: (ERCP) is common treatment used for therapeutic purposes while treating a variety of pancreatico-biliary illnesses. Study was aimed at determining the indications of the ERCP and comparing the ultrasonography and ERCP findings.

Methodology: This study was an observational, retrospective study that was conducted in the Department of Gastroenterology, The ERCP data were collected between September 2019 and December 2021. The study included 277 patients who had been diagnosed with common bile duct stones and were over the age of 18. Different ERCP indications were identified and radiographic and ERCP cholangiographic results were compared. For quantitative variables, the mean and standard deviation were documented. Qualitative variables were computed as frequencies and percentages.

Results: A total of 277 cases of CBD stones were included. There were 96 male patients (34.6%) and 181 female patients (65.4%). The mean age was 51.68±15.67years. Findings of ERCP were similar to USG, CT, and MRCP findings in 218 (78.7%) patients whereas dissimilar in 53 (19.1%) patients. Sphincterotomy, balloon Sweeps, and CBD Stenting had been performed in 221(79.8%), 163(58.8%) and 109(39.4%) patients respectively. ERCP was successfully performed in 235 84.8% patients and unsuccessful in 42(15.2%).

Conclusion: Most common indications for ERCP was CBD stone. A more successful method for stone removal was endoscopic sphincterotomy combined with balloon sweep of the common bile duct.

Keywords: Endoscopic retrograde cholangiopancreatography, common bile duct, sphincterotomy.

Stiffness onSWE as Potential Microenvironment Biomarker for Predicting Recurrence in HBV-Related HCC

Manxia Lin1, Xian Zhong1, Haiyi Long1, Xiaoyan Xie1
1The first affiliated hospital, Sun Yat-sen university Guangzhou China

Background: To explore the pathologic basis and prognostic value of tumor and liver stiffness measured pre-operatively by two-dimensional shear wave elastography (2D-SWE) in hepatitis B virus (HBV)-related hepatocellular carcinoma (HCC) patients who undergo hepatic resection.

Methods: A total of 191 HBV infected patients with solitary resectable HCC were prospectively enrolled. The stiffness of intratumoral tissue, peritumoral tissue, adjacent liver tissue and distant liver tissue were evaluated by 2D-SWE. The correlations between stiffness and pathological characteristics were analyzed in 114 patients. The predictive value of stiffness for recurrence-free survival (RFS) were evaluated and Cutoff Finder was used for determining optimal cut-off stiffness values. Cox proportional hazards analysis was used to identify independent predictors of RFS.

Results Pathologically, intratumoral stiffness was associated with stroma proportion and microvascular invasion (MVI) while peritumoral stiffness was associated with tumor size, capsule and MVI. Adjacent liver stiffness was correlated with capsule and liver fibrosis stage while distant liver stiffness was correlated with liver fibrosis stage. Peritumoral stiffness, adjacent liver stiffness and distant liver stiffness were all correlated to RFS (all p<0.05). Higher peritumoral stiffness (>49.4kPa) (HR=1.822, p=0.023) and higher adjacent liver stiffness (>24.1kPa (HR=1.792, p=0.048) were significant independent predictors of worse RFS, along with tumor size and MVI. The nomogram based on these variables showed a C-index of 0.77 for RFS prediction.

Conclusions: Stiffness measured by 2D-SWE could be a tumor microenvironment and tumor invasiveness biomarker. Peritumoral stiffness and adjacent liver stiffness showed important values in predicting tumor recurrence after curative resection in HBV-related HCC.

Diagnostic and prognostic ability of CEUS and biomarkers in hepatocellular carcinoma subtypes

Ming Xu1, Xiaoyan Xie1
1Department of Medical Ultrasons, the First Affiliated Hospital, Sun Yat-sen University Guangzhou China

Objectives: To investigate the diagnostic and prognostic value of contrast-enhanced ultrasound (CEUS) and clinical indicators of the vessels encapsulating tumor clusters (VETC) pattern and macrotrabecular-massive subtype in hepatocellular carcinoma (MTM-HCC)

Materials and methods: A total of 273 HCC patients (182 in the training cohort and 91 in the validation cohort) were included in this
prospective study. All patients received conventional ultrasound and CEUS examination, followed by surgery within one week and obtain pathological diagnosis. Multivariable logistic regression was performed to selected independent correlated factors of VETC-HCC and MTM-HCC to develop the nomogram. Nomogram models were assessed by receiver operating characteristic (ROC) curves, calibration plots, and decision curve analysis (DCA). Kaplan-meier curves analysis and Cox regression analysis were conducted to assess the association between risk stratification and early postoperative recurrence.

**Results:** VETC-HCC and MTM-HCC were found in 109 (39.9%) and 51 (18.7%) patients, respectively. Multivariate logistic regression analysis revealed that AFP level (OR 2.26 (1.49-3.42), \(P<0.001\)), intratumoral non-enhancement (OR 2.40 (1.02-5.64), \(P=0.044\)) and perfusion criterion, the AUC reached 0.917 (95% CI 0.873-0.961), with a sensitivity of 95.8% and specificity of 87.5%. ICC ranged from 0.756 to 0.907 for inter-observer agreement and 0.791 to 0.934 for intra-observer agreement for CUS and CEUS features were evaluated using the intra-class correlation coefficient (ICC).

**Conclusions:** Combining the imaging features of CUS and CEUS with age and hematuria provides a potentially effective diagnostic method in the differentiation of RUC and ERCC.

**MSC-derived Extracellular Vesicles Alleviate Ischemia Liver Injury via Inhibiting NETs Formation**

1West China Hospital, Sichuan University Chengdu China

**Background:** Transjugular intrahepatic portosystemic shunt (TIPS) is a highly efficacious approach for managing portal hypertension complications. However, portal venous shunt-related ischemia often results in liver dysfunction or failure following TIPS. This study aims to investigate the therapeutic potential of mesenchymal stromal cells (MSCs) in mitigating ischemic liver injury and elucidating the underlying mechanism.

**Methods:** We employed portal venous branch ligation to partially obstruct the blood supply to liver to establish a model of ischemic liver injury and performed transcriptome sequencing on liver tissue. interpreting imaging studies and managing patients with incidental findings of pleosisis hepati or presenting by complications.

**Abstract Submission No. 200153**

**O-0713**

**Differentiating Renal Urothelial Carcinoma and Endophytic Renal Cell Carcinoma using US and CEUS**

**Dongdong Jin**, **Jinhua Lin**, **Yan Wang**

1The Department of Medical Ultrasonics, Institute of Diagnostic and Interventional Ultrasound, The First Affiliated Hospital of Sun Yat-Sen University Guangzhou China

**Purpose:** This retrospective study aimed to evaluate the value of conventional ultrasound (CUS) and contrast-enhanced ultrasound (CEUS) features in differentiating between renal urothelial carcinomas (RUC) and endophytic renal cell carcinomas (ERCC).

**Methods:** From July 2014 to November 2022, a total of 72 patients with RUC and 118 patients with ERCC confirmed by pathology were enrolled in this study. Both CUS and CEUS were performed in all patients within 4 weeks before the procedure. Univariable and multivariable analyses were used to select statistically significant variables of clinical, CUS, and CEUS features for the differentiation of RUC and ERCC. Sensitivity (SEN), specificity (SPE), and the area under the receiver-operating characteristic curve (AUC) were assessed for diagnostic performance. Inter- and intra-observer agreements of CUS and CEUS features were evaluated using the intra-class correlation coefficient (ICC).

**Results:** Multiple logistic regression analysis demonstrated that clinical (age and hematuria), CUS (size, echogenicity, regularity, and hydronephrosis), and CEUS (non-enhancement area, enhancement intensity in cortical phase, and rim-like enhancement) features were independent factors for differential diagnosis with all \(p < 0.05\). When combining clinical characters with CUS and CEUS features into a diagnostic criterion, the AUC reached 0.917 (95% CI 0.873-0.961), with a sensitivity of 95.8% and specificity of 87.5%. ICC ranged from 0.756 to 0.907 for inter-observer agreement and 0.791 to 0.934 for intra-observer agreement for CUS and CEUS features.

**Conclusions:** Combining the imaging features of CUS and CEUS with age and hematuria provides a potentially effective diagnostic method in the differentiation of RUC and ERCC.

**A tricky Case of Pleosisis Hepatis : case report**

**Naglaa Abd El-Latif**, **Hanan Meshaal**

1Medical Research Institute Alexandria Egypt, 2Mostafa Kamel Military Hospital Alexandria Egypt

Peliosis hepatitis is a rare vascular condition of the liver characterized by a proliferation of the sinusoidal hepatic capillaries that results in hemorrhagic necrosis confirming diagnosis of peliosis hepatitis.

**Case Presentation:** A 40-year-old female presented to by acute abdominal pain and shivering. Regarding medical history She is hypertensive, has psoriatic arthritis and fibroid uterus on OCP. She has a family history of cancer pancreas. On evaluation, Hb was 8.8 g/dl, Platelets 345, WBCs 10.5 c/dl, ALT was elevated 329 u/l, AST 63 u/l, S. albumin 3.8 g/dl, total bilirubin 1 mg/dl, direct bilirubin 0.50 mg/dl. Abdominal ultrasound revealed the presence of sizable heterogeneous lesion in the pelvis. Pathological examination showed a proliferation of the sinusoidal hepatic capillaries that resulted in hemorrhagic necrosis confirming diagnosis of peliosis hepatitis. Healthcare providers should be aware of this condition when interpreting imaging studies and managing patients with incidental findings of pleosisis hepati or presenting by complications.
Additionally, we utilized MSCs derived from human umbilical cord to treat the mouse model of ischemic liver injury, elucidating the mechanism through both in vitro and in vivo experiments.

**Results:** The transcriptome sequencing and differential gene enrichment analysis revealed significant enrichment of cytokine pathways and glucose metabolism pathways. Additionally, the plasma levels of IL-6, IL-17A, MMP-9, and MPO, which serve as indicators of neutrophil activation, were found to be elevated in patients after TIPS and in mouse model. The average serum levels of AST, ALT, and bilirubin in the mice model treated with MSC were significantly reduced. MSC treatment inhibited the formation of neutrophil extracellular traps (NETs). We further confirmed that both MSC medium and MSC-derived extracellular vesicles (MSC-EVs) were able to inhibit the release of NETs from neutrophils by interfering with GSDMD shearing.

**Conclusion:** Both MSC and MSC-EV possess the potential to mitigate ischemic liver injury through hindering the NETs formation. They may be considered for the prevention of liver dysfunction after TIPS procedure.

**O-0715**

**Microwave ablation (MWA) antenna emprint visualization innovation**

YOSUKE ASAMI1, SHUICHIRO SHINA2, KOHEI TAKASHIMA1, HIDEKI HISAYASU3, NORIFUMI MARUYAMA2, MAKI TOBARI3, TOSHIHUMI YAMAGATA2

1Department of Clinical Engineering, Juntendo University Tokyo Japan, 2Department of Gastroenterology, Juntendo University Tokyo Japan, 3Department of Medical Technologist, Juntendo University Tokyo Japan

**Background:** New-generation microwave ablation (MWA) has garnered attention due to its ability to generate larger ablation volumes in shorter durations compared to radiofrequency ablation (RFA). However, MWA faces a challenge in terms of visibility under ultrasound, as the MWA antenna is less conspicuous than an electrode used in RFA.

**Purpose:** The primary objective is to enhance the visibility of Emprint electrodes, especially in cases where observation is challenging (e.g., deep, obese, postoperative patients), ensuring safe cauterization.

**Method and Results:** In instances where visibility is compromised after Emprint antenna insertion into the liver, a novel approach is employed. The saline solution used for reflux is agitated to create microbubbles. Activation of the pump sends air and saline alternately. Utilizing contrast mode on the echo side (Aplio i800) and focusing on the expected needle tip, observation is conducted. Microbubbles, reaching the antenna needle tip, highlight its position. Once confirmed, cauterization proceeds from the anticipated location.

**Discussion:** The discussion emphasizes that during contrast mode, refluxed microbubbles flow to the 4mm tip of the Emprint needle, where the sensor chip is situated. This structural feature of the Emprint is crucial for highlighting the needle tip, aiding in its visualization.

**Conclusion:** The innovative technique proves valuable for predicting the needle tip position in cases where Emprint visibility poses a challenge.

**Sonodynamic therapy improves cancer immunotherapy after insufficient radiofrequency ablation.**

**Wenxin Wu1, Tongyi Huang1, Chunyang Zhang1, Xiaoyan Xie1**

1The First Affiliated Hospital of Sun Yat-sen University, Guangzhou, China

**Background:** Residual lesions and undetectable metastasis after insufficient radiofrequency ablation (iRFA) are associated with earlier new metastases and poor survival in cancer patients. Programmed cell death protein 1 (PD-1) blockade has been reported to enhance RFA-elicited antitumor immunity, but its ability to eliminate residual lesions has been questioned. Thus, new adjuvant strategies are urgently needed to restrain iRFA-induced tumor cell progression. Here, we report a combined treatment modality post iRFA based on integrating an oxygen self-enriching PFH-Ce6 liposome@O2 nanodroplets (PCL@O2)-augmented noninvasive sonodynamic therapy (SDT) with PD-1 blockade.

**Methods and Results:** PCL@O2 containing Ce6 as the sonosensitizer and PFH as O2 reservoir, was synthesized as an augmented SDT nanoplatform and showed increased ROS generation to raise effective apoptosis of tumor cells, which also exposed more calreticulin meaning stronger immunogenic cell death (ICD). Combining with PD-1 blockade post iRFA, this optimized SDT induced a better anti-tumor response in MC38 tumor bearing mouse model, which not only arrested residual primary tumor progression, but also inhibited the growth of distant tumor, therefore prolonging the survival. Profiling of immune populations within the tumor draining lymph nodes and tumors further revealed that combination therapy effectively induced ICD, and promoted the maturation of dendritic cells, tumor infiltration of T cells, as well as activation of cytotoxic T lymphocytes. Moreover, the combined treatment could significantly initiate long-term immune memory.

**Conclusion:** this study establishes the preclinical proof of concept to apply oxygen self-enriching SDT to augment cancer immunotherapy after iRFA.

**Invitrogen Vivofectamine LNP Library for in vivo RNA delivery to liver from mouse to NHP**

Koshi Kunimoto1, Neha Parayathi1, Wen Yang1, Peter Lam1, Virginia Aragon1, Joel Jesse1, Jason Potter1, Evgenia Verovskaya1

1Thermo Fisher Scientific Carlsbad United States

The rapidly expanding use of mRNA as a therapeutic tool necessitates innovative delivery methods. Leveraging three decades of lipid-based delivery expertise, we have developed lipid nanoparticle (LNP) solutions that can efficiently deliver mRNA in vivo and ex vivo. Our leading candidates have been selected from a library of over 5000 synthesized lipids after rigorous in vitro and in vivo screening. They demonstrate high efficacy and safety across diverse applications like liver protein expression, vaccines, and immune cell targeting. Our liver-specific ionizable lipids, formulated as LNPs, were tested in mice, rats, and non-human primates (NHPs). In mice using fLuc mRNA-LNP, we observed high levels liver-specific protein expression, on par or surpassing ionizable lipids in clinical trials and FDA-approved drugs. Initial data on genome editing at the TTR locus showed over 80% reduction in circulating TTR levels and more than 50% editing in the homogenized liver.

In NHPs, three of six lipids from our exploratory panel were evaluated for delivering hEPO mRNA. Collaborator data indicated superior efficacy and safety with our leading candidate compared to a benchmark ionizable lipid used in clinical-stage mRNA liver therapies. Moreover,
this lipid exhibited excellent tolerance in rats, even at a single 9 mg/kg dose or three repeated 3 mg/kg injections each.

Our findings underscore the high efficacy and safety of liver-specific Vivofectamine™-LNP formulations. This product provides a versatile platform for diverse applications, including protein expression and genome editing. Our LNP Library aims to expedite nucleic acid delivery from bench to clinic, offering solutions to our customers’ delivery challenges.

Research use only.

Overlapping and Power Ramping Ablation Zone Techniques using the Emprint Ablation System

Joseph D Brannan¹, Flor de maria Nonalaya¹, Kim A Court¹
¹Medronic Lafayette, CO United States

INTRODUCTION: Creating overlapping ablation zones is a technique common to thermal ablation in the liver to achieve ablative margins around larger tumors. Similarly, a power ramp-up technique is common, wherein power is increased in a stepwise approach to reduce tissue popping, a phenomenon related to fluid-to-vapor phase transition, by allowing heat and pressure to disperse over a slower initial heating period. This scientific work characterizes overlapping and power ramping ablation techniques using the Emprint™ ablation system within ex vivo bovine livers.

METHODS: Ablation zones (n=284) were created within temperature-controlled ex vivo bovine livers. For the overlapping technique, both pull-back (n=92) and side-by-side (n=103) overlapping ablations were created using two sequential activations of a single Emprint device at four device spacings (0.5, 1, 1.5, 2 cm), three power settings (50, 100, 150 W), and three activation times per placement (90, 300, 600 sec). For the ramp-up technique, single-placement ablation zones (n=89) were created using nine ramping protocols, each starting at 50 W for 60 seconds. Ablation zone dimensions were measured following Triphenyltetrazolium chloride tissue staining.

RESULTS: The range of the mean for ablation volume, width, and length for overlapping pull-back was 5.8-110.3 cm³, 2.0-5.1 cm, 2.6-7.2 cm. The range of the mean for ablation volume, width, length, and length for overlapping side-by-side was 4.5-101.9 cm³, 2.0-6.2 cm, 1.8-5.1 cm, 2.1-5.3 cm. Power ramping protocols resulted in ablation volume, width, and length ranging from 4.4-61.5 cm³, 1.8-4.8 cm, 2.6-5.1 cm.

CONCLUSION: A wide range of ablation sizes and shapes are possible with the Emprint ablation system using an overlapping ablation technique, and power ramping with the system delivers small to large spherical ablations.

Refining Liver Fibrosis Assessment: Palm-sized Transient Elastography Guided with B-mode Imaging

Zihao Huang¹, Yongping Zheng¹
¹Department of Biomedical Engineering, The Hong Kong Polytechnic University Hong Kong Hong Kong

Transient elastography (TE), recommended by WHO and major clinical guidelines, has been an established method for assessing liver fibrosis via liver stiffness measurement (LSM). However, conventional TE is limited by large size and relies on difficult-to-interpret A-mode imaging for liver localization, which hinders its widespread use in hepatology field. A palm-sized wireless TE system with real-time B-mode ultrasound imaging guidance was proposed. The performance of B-mode guided TE was prospectively evaluated in three tissue-mimicking phantoms (reference values: 4.66, 12.8 and 76.9 kPa) and 60 adults with various chronic liver diseases (age, 52 ± 12.2 years; BMI, 24.0 ± 3.9 kg/m²; 30 women; 47% Chronic hepatitis B). Intra- and inter-operator reliability were further assessed in a subgroup of 30 patients using intra-class correlation coefficient (ICC). B-mode guided TE accurately estimated the Young’s modulus of the reference phantoms (averaged bias: 4.4%; range: 2%-7.9%). Pairwise comparisons revealed significant inter-correlation of LSM among B-mode guided TE, conventional TE and two-dimensional shear-wave elastography, with strongest correlation (r = 0.80) and highest agreement (mean difference of -0.51 kPa, 95% LOA: -2.95 to 1.92 kPa) observed at the pair of B-mode guided vs. conventional TE. Excellent intra-operator and good inter-operator reliability were established (ICCs: 0.883-0.925). B-mode guided TE presents a practical approach for achieving reproducible and valid LSM, comparable to other existing liver elastography techniques. Enhanced liver anatomy visualization under B-mode improves examination efficiency and shortens the learning curve for inexperienced practitioners. Its small footprint offers high portability, paving the way toward point-of-care liver fibrosis assessment.

Telemedicine for Hepatology Consultations in Myanmar: A Single Centre Experience

Soe Thiha Maung¹
¹Ma Har Myaing Hospital Yangon Myanmar

Aim: Telemedicine has witnessed a significant surge in its adoption, particularly during the COVID-19 pandemic. Over the years, it has found utility in various facets of hepatology. The main objective of this study was to assess patient satisfaction regarding Hepatology consultations conducted through a telemedicine program in a private hospital in Myanmar.

Methods: This study encompassed a series of telemedicine consultations conducted by a hepatologist at a private hospital in Yangon, Myanmar. Patients and the hepatologist utilized various communication platforms, based on their individual preferences. The consultations were done via telemedicine when they led to a diagnosis and established a suitable plan for follow-up care. To assess patient satisfaction with the telemedicine approach, the study employed the Patient Satisfaction Questionnaire Short Form and the Telemedicine Satisfaction Questionnaire.

Results: A comprehensive dataset comprising 155 telemedicine consultations conducted by the hepatologist. Notably, all these consultations were successfully resolved through the telemedicine approach. The final diagnoses for the patients whose consultations were effectively managed via telemedicine encompassed chronic hepatitis B (70%), hepatocellular carcinoma (18%), non-alcoholic fatty liver disease (7%), and benign hepatic lesions (5%). Our findings revealed a notably high level of patient satisfaction with the telemedicine model, as evidenced by positive responses in both questionnaires utilized.

Conclusion: The outcomes of our study underscore the efficacy of telemedicine within the realm of hepatology. Our findings revealed a pronounced level of patient satisfaction, as evidenced by the use of validated questionnaires, which bolsters the case for the continued utilization of telemedicine in hepatological practice.
Intravascular ultrasound-guided direct portal vein puncture for TIPS: A proof-of-concept study

Anbang Chen	extsuperscript{1}, Zhen Li	extsuperscript{2}, Yifu Xia	extsuperscript{1}, Guangjun Huang	extsuperscript{2}, Lianhui Zhao	extsuperscript{1}, Zheyu Niu	extsuperscript{1}, Shaolei Han	extsuperscript{2}, Guangchuan Wang	extsuperscript{1,2}, Chunqing Zhang	extsuperscript{3} \\	extsuperscript{1}Department of Gastroenterology, Shandong Provincial Hospital, Shandong University Jinan China, 	extsuperscript{2}Department of Gastroenterology, Shandong Provincial Hospital Affiliated to Shandong First Medical University Jinan China, 	extsuperscript{3}Department of Infectious Disease, Qilu Hospital, Cheeloo College of Medicine, Shandong University Jinan China, 	extsuperscript{4}Department of Hepatobiliary Surgery, Shandong Provincial Hospital Affiliated to Shandong First Medical University Jinan China, 	extsuperscript{5}Center for Liver Disease, Shandong Public Health Clinical Center Jinan China

Background: Portal vein (PV) puncture is the most challenging and time-consuming step in the transjugular intrahepatic portosystemic shunt (TIPS) procedure. Conventional intravascular ultrasound (IVUS)-guided PV puncture separates the ultrasound probe and puncture needle in different veins, providing indirect guidance but increasing procedural complexity. The purpose of this study was to evaluate the technical feasibility and safety of IVUS-guided direct PV puncture via the right hepatic vein (RHV) for TIPS in a live canine model.

Methods: Five healthy beagle dogs were selected and anesthetized. The 6.6-millimeter diameter phased-array side-firing endoscopic ultrasound was introduced as the IVUS. The ultrasound probe was inserted into the RHV via a right jugular vein approach. Under direct ultrasound guidance, PV puncture was performed using a 21-gauge needle through the entrance of the RHV. Guidewire insertion, tract dilation, and stent placement were subsequently completed. The efficacy of IVUS-guided direct PV puncture via RHV was assessed.

Results: Among the five beagle dogs, one case cannot insert an ultrasound probe due to the small diameter of the jugular vein. The remaining four completed the IVUS-guided direct PV puncture via RHV and TIPS creation without technical problems or complications. No adverse events occurred in animals during the 6-month observation. Necropsy of animals revealed no evidence of stent displacement, stent stenosis, or puncture complications.

Conclusion: Our experimental model demonstrated that IVUS-guided direct PV puncture via RHV for TIPS is both technically feasible and safe, which may be the foundation of a specialized IVUS-guided integrated puncture system in TIPS creation.

Abstract Submission No. 101067

Augmented Reality Navigation for Laparoscopic Liver Surgery: A Comparison with ICG Fluorescence

Meidai Kasai	extsuperscript{1}, Tukasa Aihara	extsuperscript{1}, Goshi Matuki	extsuperscript{1}, Noriko Ichise	extsuperscript{1}, Masataka Fujikawa	extsuperscript{1}, Takayoshi Nakajima	extsuperscript{1}, Yoshihiko Nakamoto	extsuperscript{1}, Hidenori Yanagi	extsuperscript{1}, Hideaki Uchiyama	extsuperscript{1}, Naoki Yamanaka	extsuperscript{1} \\	extsuperscript{1}Department of Surgery, Meiwa Hospital Hyogo Japan, 	extsuperscript{2}Graduate School of Science and Technology, Nara Institute of Science and Technology Nara Japan

Objective: Augmented reality (AR) is gradually becoming prevalent in the medical field, especially for surgical assistance. It is useful in overlaying preoperative 3D images with intraoperative visuals to understand the spatial relationship between tumors and blood vessels. However, the accuracy of matching real organs with AR, considering abdominal organ deformation due to pneumoperitoneum or respiratory variations, remains unclear. This study aims to implement overlay displays considering liver deformation through non-rigid registration and compare it with the fluorescence regions identified by the Indocyanine Green (ICG) fluorescence method.

Subjects and Methods: Four cases identified using the ICG fluorescence method were selected. Annotations were made on liver silhouette and fluorescence-stained areas for silhouette-based alignment. 3D liver models were created from CT images using SYNAPESE VINCENT (Fujifilm). AR display was conducted using the open-source program RBOT (Region-based Object Tracking) for pose estimation. Finally, registration of the liver silhouette was performed using the medical image registration library SimpleITK. The Hausdorff distance and IOU (Intersection over Union) were calculated between the ICG fluorescence area and AR liver region mapping for accuracy evaluation.

Results and Discussion: The non-rigid registration before and after showed Hausdorff distances and IOU of 13.8 ± 13.1mm and 0.58 ± 0.63, respectively, indicating a slight improvement in accuracy with non-rigid registration. While this method faces challenges, such as manual setting of initial positions, leveraging open-source programs and future enhancements including Al-based initial position estimation could lead to more accurate AR displays.

Abstract Submission No. 101329

An Equivalence Design to compare two non-invasive tools to predict Esophageal Varices in Cirrhosis

Arum Prabhakaran	extsuperscript{1}, Srijaya S Sreesh	extsuperscript{1}, Jesse J Skariah	extsuperscript{1}, Devika Madhu	extsuperscript{1}, Krishnadas Devadas	extsuperscript{1} \\	extsuperscript{1}Department of Medical Gastroenterology Thiruvananthapuram India

Background: We evaluated the diagnostic performance and Equivalence of Shear wave elastography (SWE), vibration controlled transient elastography (VCTE) and other non-invasive parameters in their predictive ability to detect the presence of esophageal varices and high-risk esophageal varices in patients with compensated cirrhosis of liver.

Methods: 108 patients with compensated cirrhosis of liver who underwent SWE, VCTE, endoscopy and base-line investigations were enrolled. Comparisons of the accuracy of prediction between groups were made by AUROCs. Regression analysis was performed for multiple variables.

Results: There were 64 males and 44 females, with a mean age of 51.73 ± 11.35 years. The predominant aetiologies were NASH (40%) and Alcohol (27%). Esophageal varices were detected in 63 patients, of which 36 patients had high-risk varices. The AUROC value of SWE (0.967) was comparable to that of VCTE (0.961) but significantly higher than other non-invasive parameters (platelet count, spleen diameter, platelet count/spleen diameter ratio, FIB-4, APRI). SWE had 92.1% sensitivity, 88.7% specificity, 90.6% PPV, and 88.6% NPV for predicting the presence of varices at an optimal cut-off value > 21.1 kPa, and 91.7% sensitivity, 88.6% specificity, 80.2% PPV, and 95.1% NPV for predicting high-risk varices at an optimal cut-off value > 24.6 kPa. No patient with SWE value < 20.3 kPa had varices.

Conclusion: The Equivalence of the predictive ability of SWE and VCTE to detect the presence of varices and high-risk varices is demonstrated in our study. The other non-invasive parameters were found to be inferior to them.
Mimic nanovesicle with Enhanced PD-1 Expression Induce Immunomodulation for immunotherapy after iRFA

Chuyang Zhang1, Hualing Guo1, Haiyi Long1, Ming Xu1, Xiaoyan Xie1
1Department of Medical Ultrasound, First Affiliated Hospital, Sun Yat-Sen University. Guangzhou China

Background: Radiofrequency ablation (RFA) was one of the most effective treatments for controlling early HCC. However, the recurrence rate remains as high as other treatment modalities owing to immunosuppressive tumor microenvironment. As reported, Lenvatinib blockade of FGF Receptor 4, leading to the decrease the expression of tumor-PD-L1 and restriction of Treg differentiation. Herein, we synthesized a macrophage-membrane modified nanovesicle with enhanced PD-1 expression for reversing the immunosuppressive tumor microenvironment and enhance the adaptive immune response after insufficient RFA (iRFA).

Methods: The synthesized nanovesicle LMP@Len was consisted of a lipid/macrophage-membrane (enhanced PD-1 expression) shell for carrying Lenvatinib. The characterization of LMP was evaluated by TEM and Nano ZS90. The fusion of lipid and membrane was detected by CLSMs and Flow cytometry assay. Cytoxicity of LMP were detected by CCK-8 assay. Flow cytometry and immunofluorescence staining were applied to investigate the effect of LMP on reversing immunosuppressive microenvironment of residual tumor.

Results: The synthesized LMP@Len can significantly avoid the phagocytosis by kuffer cell in vitro and more effectively accumulated in tumor cite than the liposome in vivo. The combination therapy of Lenvatinib and the PD-1 antibody expressed on the macrophage-membrane effectively inhibited the recurrence of Hepa-16 tumor. The infiltration percent of Tregs decreased to 1.02±0.50% in treatment group compared with 3.64±0.90%. Compared with iRFA group, the infiltration of CD8+ T cells increased 2 folds with the combination therapy.

Conclusion: Blocking PD-L1 and Tregs was an attractive strategy to enhance the therapeutic efficacy of ICB with LMP@Len.

FLNA cargo in exosome promote pre-metastatic niche formation in intrahepatic cholangiocarcinoma

Fan Mu1, Liangshuo Hu1, Bo Wang1, Kun Xu1
1First Affiliated Hospital of Xi’an Jiaotong University Xi’an China

Background: Lymph node metastasis is a frequent occurrence in patients with intrahepatic cholangiocarcinoma (ICC), which makes patients suffer from worse outcome. Accumulating evidences have shown that pre-metastatic niche (PMN) formation play an irreplaceable role in lymph metastasis preferentially development. However, the biogenesis and media of PMN formation in ICC remains unclear.

Methods: Effects of exosome separated from ICC cell lines were confirmed by western-blot and other phenotype analyses. The exosomal protein for promoting Lymphatic metastasis were verified by intravenous injection of ICC-derived exosomes and sleeping beauty system. Mouse intrahepatic cholangiocarcinoma models via hydrodynamic were applied for scRNA-seq, aiming to detect the landscape of PMN in lymph node.

Results: Our results indicate that Filamin A (FLNA) as an oncogene in ICC, FLNA specifically regulate extracellular vesicle cargo selection. Incubating human lymphatic endothelium cell with ICC cell-secreted exosomes increases tube forming capacity, which contributes to the formation of PMN in lymph node. We also found ICC cell-secreted exosome promoting the PD-1 expression of CD8+ T-cell, which consequently accelerates immune escape, both effects related with the FLNA expression in tumor. Moreover, FLNA level in serum exosome of ICC patients with lymph metastasis is significantly higher than those with negative lymph node.

Conclusion: Our results indicate that FLNA plays an important role in educating lymphocytes and endothelial cells, which associated with the formation of PMN in lymph node. The data from mouse and patient samples further reflect FLNA as a potential target for clinical diagnosis and treatment of intrahepatic cholangiocarcinoma lymph node metastasis.
Etsushi Kawamura1, Tsutomu Matsubara2, Masaru Enomoto1, Kazuo Ikeda3, Naoshi Odagiri1, Norifumi Kawada4, Kohei Kotani5, Atsuko Daikoku6, Chihito Kadono7, Hitoto Yasu2
1. Department of Hepatology, Graduate School of Medicine, Osaka Metropolitan University Osaka Japan, 2. Department of Anatomy and Regenerative Biology, Graduate School of Medicine, Osaka Metropolitan University Osaka Japan, 3. Department of Veterinary Pathology, Graduate School of Veterinary Science, Osaka Metropolitan University Osaka Japan

Purpose: Our study aimed to elucidate the molecular pathology underlying intrahepatic cholangiocarcinoma (ICC) growth through comprehensive RNA analysis of clinical samples.

Method: RNAs were extracted from serum exosomes and tumor tissues of 24 patients (average age: 63.8 years) undergoing surgical resection for hepatobiliary tumors at our hospital. The cohort included 10 cholangiocarcinomas, 10 hepatocellular carcinomas, and 4 benign tumors. High-sensitivity microarray and in silico screening identified differentially regulated RNAs among tumor groups.

Results: High-ranked RNAs were selected by target database, resulting in a focus on microRNA-3648 (targeting LPL, SKI, and APC2). Assessment of these target mRNAs in the human ICC cell line (OZ), overexpressing microRNA-3648, revealed a 6.7-fold decrease in SKI protein expression compared to negative controls (ANOVA p < 0.01). SKI-overexpressing OZ showed increased p21 expression at mRNA, protein, and promoter luciferase levels (2.6-fold increase, 2.1-fold increase, 1.5-fold increase; ANOVA p < 0.01, < 0.05, < 0.05), inhibiting cell proliferation and DNA replication factor CDT1 protein expression (1.8-fold decrease, 1.5-fold decrease; t-test p < 0.01, < 0.05) vs. negative controls, respectively. The p21 protein increase disappeared in OZ overexpressing SKIΔ, a plasmid with a deleted p21 transcription-related amino acid sequence (1.6-fold decrease vs. SKI plasmid, t-test p < 0.05). As a preliminary analysis, immunostaining in a mouse model of chemically induced precancerous bile ducts showed SKI-positive regions were Ki-67 negative.

Conclusion: Our findings suggest that SKI protein suppresses ICC growth (in vitro/in vivo) through p21 gene transcription (in vitro).

Prevalence of Chronic Liver Disease in Cholangiocarcinoma - A single arm metaanalysis of 113 studies

Shanya Zhuoyu Gunalan1, Daniel Q Huang2, Cheng Han Ng1,2,3, Mark Mutthiah1,2,3, Benjamin Koh1, Christen En Ya Ong1, Nicole Shu Ying Tang1, Margaret Teng1,2,3
1. Yong Loo Lin School of Medicine, National University of Singapore Singapore Singapore, 2. National University Centre for Organ Transplantation, National University Health System Singapore Singapore, 3. Division of Gastroenterology and Hepatology, Department of Medicine, National University Hospital Singapore Singapore

Background: Chronic liver disease (CLD) is a well-associated risk factor for cholangiocarcinoma (CCA). Despite long-standing association, the population of patients with concurrent CCA and CLD remains poorly characterised. Recent data suggests potential prognostic implications of CLD in CCA.

Methods: In this single-arm meta-analysis, we searched MEDLINE and EMBASE from inception to 6th June 2023 for English articles containing information for CCA patients with and without CLD. Population data was pooled to obtain the prevalence of different CLDs within CCA population and stratified by geography and tumor location.

Results: In total, 136346 CCA patients and 17909 CCA patients with concomitant CLD were identified. Amongst CCA patients, cirrhosis was the most prevalent CLD (n = 6426), followed by HBV (n = 3936), and HCV (n = 1536). Mean age of CCA patients with concomitant CLD was 62.3 years old while mean age of non-CLD CCA patients was 65.3 years old. Cumulative mean tumour size was 5.74 cm amongst CCA patients and 5.92 amongst non-CLD CCA patients. Analysis of 113 studies showed overall prevalence of 24.8% (95% CI: 20.3 to 29.9%). By geography, CLD was most prevalent in the Eastern Mediterranean (42.4%, 95% CI: 38.2 to 46.7%), followed by Western Pacific (35.7%, 95% CI: 27.7 to 44.6%). By tumor location, CLD was most common in intrahepatic (36.3%, 95% CI: 28.8 to 44.5%) and perihilar CCA (24.8%, 95% CI: 10.7 to 47.5%) respectively.

Conclusions: Our results highlight the significant prevalence of CLD amongst the CCA population, allowing insight into a prominent CCA subgroup.
The Efficacy of Total Tumor Volume in Patients with Colorectal Liver Metastases

Yuhi Shimura1, Shohei Komatsu1, Akihiro Fujisawa1, Masahiro Kido1, Hitotoshi Gon1, Kenji Fukushima1, Toshihiko Yoshida1, Keisuke Arai1, Masayuki Akita1, Jun Ishida1, Yoshiohe Nanno1, Daisuke Tsugawa1, Takumi Fukumoto1

1Department of Surgery, Division of Hepato-Biliary-Pancreatic Surgery, Kobe University Graduate School of Medicine Kobe Japan

Background: Few reports have discussed the association between total tumor volume (TTV) and prognosis in patients with colorectal liver metastases (CRLM). The present study aimed to evaluate the usefulness of TTV for predicting recurrence-free survival and overall survival (OS) in patients receiving initial hepatic resection or chemotherapy, and to investigate the value of TTV as an indicator for optimal treatment selection for patients with CRLM.

Methods: This retrospective cohort study included patients with CRLM who underwent hepatic resection or chemotherapy (n = 78) at the Kobe University Hospital. TTV was measured using 3D construction software and computed tomography images.

Results: A TTV of 100 cm³ has been previously reported as a significant cut-off value for predicting OS of CRLM patients receiving initial hepatic resection. For patients receiving hepatic resection, the OS for those with a TTV ≥ 100 cm³ was significantly reduced compared with those with a TTV < 100 cm³. For patients receiving initial chemotherapy, there were no significant differences between the groups divided according to TTV cut-offs. Regarding OS of patients with TTV ≥ 100 cm³, there was no significant difference between hepatic resection and chemotherapy (p = 0.160).

Conclusions: TTV can be a predictive factor of OS for hepatic resection, unlike for initial chemotherapy treatment. The lack of significant difference in OS for CRLM patients with TTV ≥ 100 cm³, regardless of initial treatment, suggests that chemotherapeutic intervention preceding hepatic resection may be indicated for such patients.

Hepatic arterial infusion is effective in patients with unresectable colorectal liver metastases

Masatsugu Ishii1,2, Satoshi Itano1, Osamu Itano3

1Department of Gastroenterology, Kurume Chuo Hospital, Fukuoka Japan, 2Department of Hepato-Biliary-Pancreatic Surgery, Tochigi Cancer Center, Tochigi Japan, 3Department of Hepato-Biliary-Pancreatic & Gastrointestinal Surgery, School of Medicine, International University of Health and Welfare. Chiba Japan

We identified an effective chemotherapy regimen in patients who are refractory to standard chemotherapy. We included patients with unresectable colorectal liver metastases who underwent hepatic artery infusion chemotherapy and systemic chemotherapy between January 2015 and December 2022. Patients received either biweekly oxaliplatin and 5-fluorouracil through hepatic artery infusion chemotherapy as well as bevacizumab and leucovorin injected intravenously (HAIC-FOLFOX-B) or biweekly irinotecan and 5-fluorouracil by hepatic arterial infusion chemotherapy and bevacizumab and leucovorin injected intravenously (HAIC-FOLFIRI-B). Of the 42 patients, 20 underwent HAIC-FOLFOX-B while 22 underwent HAIC-FOLFIRI-B treatment with response rates of 25% and 4.5%, respectively. The median overall survival and progression-free survival were 12.9 and 4.7 months and 17.4 and 7.7 months in patients undergoing HAIC-FOLFOX-B and HAIC-FOLFIRI-B, respectively. Of the 11 patients who had undergone oxaliplatin-based chemotherapy, eight received HAIC-FOLFOX-B and three received HAIC-FOLFIRI-B. The median overall survival and progression-free survival periods including the previous systemic chemotherapy period were 30.8 and 8.0 months, respectively. HAIC-FOLFOX-B and HAIC-FOLFIRI-B may improve survival in patients with unresectable colorectal liver metastases and in those who underwent both systemic oxaliplatin-based and irinotecan-based chemotherapies and were refractory to them. HAIC FOLFOX-B/FOLFIRI-B regimens may be effective therapeutic options for patients with unresectable colorectal liver metastases refractory to standard systemic chemotherapy.

High-risk CRLM can provide excellent survival through multidisciplinary treatment including ablation

Toru Beppu1, Kensuke Yamamura1, Ryuichi Karashima3, Nobuyuki Ozaki2, Eri Oda1, Takatoshi Isiko1

1Department of Surgery, Yamaga City Medical Center Yamaga Japan

Introduction: Beppu score can predict postoperative disease-free survival for patients with resectable colorectal liver metastases (CRLM). Based on the Beppu score, three groups were clearly estimated by recurrence-risk stratifications as low-risk (≤6 points), moderate-risk (7-10 points), and high-risk (≥11 points). For high-risk patients, hepatectomy following preoperative chemotherapy is recommended. We evaluated the treatment efficacy, focusing on the combination use of local ablation.

Patients and Methods: Between April 2016 and April 2022, twenty patients with CRLM diagnosed as technically unresectable or oncologically high-risk were evaluated. After induction chemotherapy, conversion surgery using hepatectomy with or without local ablation was immediately attempted. Local ablation was permissive for patients with effective chemotherapy, CRLM ≤ 2cm, and ≥5mm distant from major vessels.

Results: The largest diameter and number of CRLM were 15cm and 46, respectively. Preoperative chemotherapy was performed for 18 patients, and all of them were judged as disease control. Local ablation was simultaneously conducted in 14 patients; all tumors were within the selection criteria: the median number was 3 (1-21), and the median diameter was 12.5mm (5-17mm). Local recurrence rates at the ablation sites were 7/82 (8.5%) per nodule. Three-year disease-free and five-year overall survival were 57.4% and 56.2%, respectively. There were no significant differences in patients with or without local ablation.

Conclusion: Our treatment strategy for patients with high-risk CRLM is feasible and can provide an excellent long-term prognosis instead of the additional use of local ablation on hepatectomy.
Radio-Frequency Ablation of Hepatic Metastases from Sarcoma

Yukihiro Koike1, Eriko Goto2, Tsuyoshi Ohno3, Katsuhito Takahashi3

1Osaka University Osaka Japan
2Hospital Tokyo Japan, 3Kameda General Hospital Chiba Japan

**Background:** In the previous study, we reported that IL-33 level was elevated by hepatocytoma, and intrahepatic cholangiocarcinoma (iCCA) cells growth were facilitated by adding cancer associated fibroblasts (CAFs) culture medium treated with IL-33, however the specific mechanism is still unknown.

**Methods:** We compared the proliferation and migration ability among following three groups: control group: iCCA cell were incubated in normal culture medium, IL-33(+) group: iCCA cells were incubated by adding condition medium of fibroblasts in cancer (CM-FiC) treated with IL-33, and IL-33(+) anti-IL-6 group: iCCA cells were incubated by adding CM-FiC treated with IL-33 and anti-IL-6 antibody. Furthermore, murine experiments were performed and compared the tumor progression among following six arms: laparotomy arm, hepatectomy arm, laparotomy and co-transplantation with fibroblasts of murine iCCA cancer (mFiC) arm, hepatectomy and co-transplantation with mFiC treated with anti-IL-6 antibody arm, and hepatectomy and co-transplantation with mFiC treated with anti-IL-6 antibody arm.

**Results:** The malignant potencies of iCCA cells in both proliferation and malignant ability was facilitated by adding CM-FiC (p<0.001, p<0.05). Furthermore, both proliferation and migration ability were decreased by anti-IL-6 treatment (p<0.001, p<0.05). And in vivo experiments, the tumor size was larger in mFiC co-transplantation arms than not co-transplantation arms (p<0.05), and the tumor size was reduced approximately 50% with anti-IL-6 treatment.

**Conclusion:** Our results suggested that IL-33 facilitated iCCA progression through increasing the secretion of IL-6 from CAFs.

Abstract Submission No. 200261 O-0734

Radio-Frequency Ablation of Hepatic Metastases from Sarcoma

Yukihiro Koike1,2, Eriko Goto3, Tsuyoshi Ohno1, Katsuhito Takahashi3

1Fuchinobe General Hospital Sagamihara Japan, 2Kanto Central Hospital Tokyo Japan, 3Kameda General Hospital Chiba Japan

**Background:** The liver is the most common site of metastases from sarcoma. At present, surgery is considered to be the only therapy that offers the possibility of cure for patients with hepatic metastatic diseases. However, there are not many patients with the metastases treatable by the surgical resection, while remaining are treated with chemotherapy or best supportive care. This study was conducted to clarify the safety and efficacy of percutaneous radiofrequency ablation (RFA) for unresectable liver metastases from sarcoma.

**Methods:** 2004 to 2013, 143 patients with unresectable liver metastases from sarcoma were treated by RFA. The mean number and size of hepatic tumor foci were, 5.6 and 60mm, respectively. 114 patients had extrahepatic metastases. 97 patients were nonresponders to previous chemotherapy.

**Results:** 143 patients had received a total of 333 RFA procedures. There was no procedure-related mortality. 9 complications were observed. At the initial ablation, all the patients enjoyed the benefit of volume reduction (>80%) of metastatic tumors. 1-, 2-year survival were 86% and 68%. Multivariate analysis showed no significant prognostic factors.

**Conclusions:** This study showed RFA could safely reduce the volume of hepatic metastases, and might improve the prognosis of patients with unresectable liver metastases from sarcoma.

Abstract Submission No. 100522

Hepatic lymphoma diagnosed by liver biopsy:
Clinicopathological features of 15 Japanese patients

Koji Uchino1, Keiko Nakamura1, Go Endo1, Ayako Nakada1, Hirobumi Suzuki2, Shizuo Yamamoto1, Yukiko Ito1, Hiroyoshi Taniguchi1, Nobuhiro Tsuchida2, Tadao Ishida1, Yuan Bae1, Toshio Kumasaka1, Hideo Yoshida1

1Department of Gastroenterology, Japanese Red Cross Medical Center Tokyo Japan, 2Department of Hematology, Japanese Red Cross Medical Center Tokyo Japan, 3Department of Pathology, Japanese Red Cross Medical Center Tokyo Japan

**Background:** Malignant lymphomas are sometimes associated with liver involvement.

**Methods:** Fifteen cases of hepatic lymphoma diagnosed by liver biopsy at our institution from January 2008 to October 2023 were included.

**Results:** The patients were 6 males and 9 females with a mean ages of 70.1 ± 13.3 years at the time of liver biopsy. Pathological diagnoses based on liver biopsy included 6 cases of diffuse large B-cell lymphoma, 4 cases of intravascular large B-cell lymphoma, 3 cases of peripheral T-cell lymphoma, 1 case of unclassified T-cell lymphoma, and 1 case of follicular lymphoma. Mass formation in the liver was observed in 9 of the 15 cases. The remaining 6 cases were diagnosed by background liver biopsy. Of the 9 cases in which liver masses were detected, 2 cases had single, 1 case had two, and the rest had three or more. Most of the hepatic lesions were hypoechoic on ultrasound. Duct-penetrating sign within the mass was seen in 6 of the 9 cases. Special imaging findings included bile duct dilatation at the periphery of the mass in one case and low-density areas along the Glisson's capsule on computed tomography in one case. Lymph node lesion was observed at the time of liver biopsy in 6 of the 15 cases. In only 1 case, no lymphoma lesions other than the liver were detected. One patient required blood transfusion due to intra-abdominal bleeding after liver biopsy.

**Conclusion:** Liver biopsy is important in the diagnosis of lymphoma with liver involvement.

Abstract Submission No. 100532 O-0735

A case of spontaneous rupture of a giant hepatic hemangioma

Shiori Kaji1, Ryo Shimizu1, Yoshiyuki Ida1, Hiroki Yamada4, Shuya Maeshiba1, Reiko Ashida1, Takao Maekita1, Mikiyaka Iguchi1, Masayuki Kitano1

1Wakayama Medical University Wakayama City Japan

**Background:** Spontaneous rupture of a hepatic hemangioma is rare, but a large amount of bleeding can be fatal. In this report, we describe a case of spontaneous rupture of a hepatic hemangioma that was treated with transcatheter arterial embolization (TAE) followed by surgery.

**Case:** A 46-year-old woman was referred to our department for a close examination of a 10 cm-sized mass in the right lobe of the liver after a simple computed tomography (CT) scan of the abdomen for anemia and anorexia. She was diagnosed as hepatic hemangioma based on fill-in enhancement on contrast-enhanced CT. She developed right hypochondriac pain without any trigger and returned to our department. Contrast-enhanced CT showed a hematoma in the right paracolic gutter, and she was admitted to our department with a diagnosis of spontaneous rupture of a hepatic hemangioma. Angiography was performed on the same day, and TAE was performed on the distal, full-
distal, and posterior segment branches of the right hepatic artery to prevent rebleeding. At a later date, she underwent a laparoscopic S5 + S6 partial hepatic resection.

**Conclusion:** Among patients with hepatic hemangioma, absolute indication for surgery is considered to be bleeding or Kasabach-Merritt syndrome, but relative indications for surgery are not clearly defined. According to a previous report, hepatic hemangiomas larger than 10 cm have a significantly higher risk of bleeding, and surgery may be considered for lesions larger than 10 cm with abdominal symptoms or coagulopathy.

**The Chemotherapy Response Prediction Based on Radiomics Method in Liver Metastasis: a Meta-Analysis**

Mochamad Affifudin1

1Clinical Department, Islamic University of Indonesia Yogyakarta Indonesia

**Background:** Addressing heterogenous chemotherapy response in liver metastasis is challenging. The using of imaging modality in addition to RECIST evaluation is known to have positive impact regarding the accuracy level. Radiomics method as machine learning application is thought to provide more objective interpretation. The scope of this study was to perform meta-analysis about the application of radiomics method in the evaluation of chemotherapy response in liver metastasis patient.

**Method:** Literature was systematically searched from PubMed over the last five years. The articles were original research that using artificial intelligence to assess chemotherapy response based on radiology imaging in liver metastases. The data extraction was analysed in R-Studio by Dersimilian-Laird method.

**Results:** Three studies were included with total 426 number of datasets. All studies have colorectal cancer as primary tumour and computed tomography as imaging modality. Those included study has different chemotherapy regimens, including: FOLFOX-based therapy, HER2-targeted therapy, and Oxaliplatin-Irinotecan. The machine learning used is also different, including deep convolutional neural network, logistic regression modelling, and Gaussian Naive Bayesian classifier. The meta-analysis showed that sensitivity was 0.956 (95% CI 0.885-0.984; p=0.05, I2=66%), specificity was 0.549 (95% CI 0.478-0.617; p=0.25, I2=29%), negative likelihood ratio was 0.091 (95% CI 0.030-0.274; p=0.38, I2=40%), positive likelihood ratio was 2.080 (95% CI 1.593-2.714; p=0.326, I2=11%), and diagnostic odds ratio was 27.148 (95% CI 7.813-94.337; p=0.12, I2=53%).

**Conclusion:** Radiomics method has good accuracy to predict chemotherapy response in liver metastasis patient and its significantly different of sensitivity than conventional model that use the interpretation of oncological radiologist.

**Neoadjuvant FOLFOXIRI therapy for patients with colorectal liver metastasis**

Masao Nakajima1, Yukio Tokumitsu1, Yoshitaro Shindo1, Hiroto Matsui1, Yuta Kimura1, Shinobu Tomochika1, Kou Kanesada1, Michihisa Iida1, Yusaku Watanabe1, Shigeru Takeda1, Tatsuya Ioka1, Hiroaki Nagano1

1Dept. of Gastroenterological and Breast and Endocrine Surg. Yamaguchi Univ. Ube Japan, 2Yamaguchi Univ. Hosp. Cancer Ctr. Ube Japan

**Background:** Based on our previous analysis, patients with H2/3 or ≥3 in number colorectal liver metastases (CLM) are considered high risk (HR)-CLM with poor prognosis even after radical resection. For these patients, we’ve performed FOLFOXIRI therapy (4 courses) as neoadjuvant chemotherapy (NAC). In this study, we investigated the safety and efficacy of NAC-FOLFOXIRI therapy in patients with technically resectable HR-CLM.

**Methods:** Fifteen patients diagnosed with HR-CLM and treated with NAC-FOLFOXIRI between 2020 and 2023 were included. Their treatment modalities and short-term outcomes were evaluated retrospectively. Values are expressed as median.

**Result:** Patient background was 64 years of age, 13 cases of synchronous metastasis, maximum diameter of liver metastasis 38 mm, and 4 tumors. About half of the patients had G3 or greater AEs, but all patients completed the scheduled NAC. The tumor reduction rate was 38.4%, and RECIST evaluation showed 8 cases of PR, 6 cases of SD, and 1 case of PD. 11 patients underwent hepatic resection, excluding 1 case of PD, 1 patient who died of other disease, 1 patient who refused surgery, and 1 patient with liver dysfunction. Five of the 11 patients underwent liver resection with more preserved liver function compared to the planned procedure before NAC. After operation, one patient died due to liver failure, but the others had no severe complications, and the median postoperative hospital stay was 11 days. The died patient had significant hepatic atrophy and liver dysfunction (ICG 18%) after NAC. Therefore we now consider a liver volume reduction of <10% and ICG <15% after NAC as an indication for hepatectomy.

**Liver-Directed Microwave Ablation of Oligometastatic Renal Cell Carcinoma in a Cirrhotic Patient**

Rene John Febro1, Hyacinth Maurielle Van Eviota1, Jaqueline Arsenal1, Salubhadhin Andam1, Maria Rossea Monfero1, Erika Johann Tanada1, Melchor Chan1, Stephen Wong1

1University of Santo Tomas Hospital Manila Philippines

**Background:** Metastatic renal cell carcinoma (RCC) to the liver is not uncommon and portends poor prognosis. However, studies illustrated that patients with cirrhosis have a decreased risk of acquiring liver metastases. No reports yet of liver-directed therapies in a cirrhotic patient with RCC. We present a unique case of oligometastatic RCC in a patient with liver cirrhosis who successfully underwent liver-directed microwave ablation (LD-MWA) prior to nephrectomy.

**Case Description:** A 64-year-old obese, diabetic female sought consult due to flank pain. Work-up revealed pyuria and microscopic hematuria, and a left renal mass on ultrasound. Computed tomography (CT) showed a 5x6x6 cm mass at the left kidney; with noted cirrhotic liver with hypodense lesions at right lobe; chest CT was unremarkable. Liver function was preserved, and AFP was normal. Same session ultrasound-guided percutaneous liver biopsy and microwave ablation of the lesions were done. Post-ablation imaging showed complete ablation. Liver biopsy exhibited carcinoma with clear cell features. Patient underwent laparoscopic radical nephrectomy with uneventful postoperative course.

**Conclusion:** Patients with oligometastatic RCC in a cirrhotic liver represent a challenging case requiring multidisciplinary management. LD-MWA as an alternative to surgical metastatectomy, may be offered in these cases. Further studies are needed to identify patients who will benefit most from this strategy.
Conclusion: NAC-FOLFOXIRI for technically resectable HR-CLM may contribute to liver parenchymal preservation, but liver dysfunction should be noted.

Abstract Submission No. 101434

O-0740

Title: Dark spots without a trace - a case of melanoma of unknown primary in the liver

Shann Long1, Alyssa Sim1

1Department of Gastroenterology & Hepatology, Tan Tock Seng Hospital, Singapore Singapore Singapore

Background: Malignant melanoma (MM) is an aggressive neoplasm with increasing incidence. In 3.2% of cases, Melanoma of Unknown Primary (MUP) behaves as an occult melanoma where no primary is found. We report a case of MUP presenting as liver lesions.

Case report: A 54-year-old lady with no significant past medical history presented to hospital with unintentional weight loss. Computed Tomography (CT) scan showed prominent supraclavicular and hilar lymph nodes and multiple indeterminate hepatic lesions. There was no liver cirrhosis. In this admission, she was newly diagnosed with Pulmonary Tuberculosis (TB), and started on treatment. Laboratory tests done revealed an incidental past Hepatitis C infection, but liver function tests and alpha-fetoprotein were normal. With further Magnetic Resonance Imaging (MRI) of the liver, differential diagnoses were either multifocal hepatocellular carcinoma, liver metastases or hepatic tuberculosis, in view of newly diagnosed TB. She underwent a percutaneous liver biopsy of the lesions and histology confirmed a melanoma. Full clinical examination identified no suspicious cutaneous lesions. Upper and lower endoscopy were negative for gastrointestinal malignancies. Ophthalmological evaluation revealed no uveal lesions and nasoendoscopy was normal. Positron emission tomography (PET) also demonstrated no obvious primary malignancy. Despite this, she remained well with no hepatic complications from the liver lesions and was started on immunotherapy of Nivolumab by the oncologist as treatment for MUP.

MM presenting as liver lesions is rare and requires thorough physical examination and corresponding investigations to search for the primary lesion. If the primary is not identified, MUP should be considered.

Abstract Submission No. 101481

O-0741

Patterns of liver metastasis in ovarian cancer

Harshita Dubey1, Amar Ranjan1, Shuvrjyoti Mondal1

1AIIMS, Delhi NEW DELHI India

Introduction: In ovarian cancer, the liver is involved via two mechanisms; liver parenchymal invasion (LPI) from perihepatic peritoneal metastasis (FIGO stage III) and hematogenous spread (FIGO stage IV) with the second one having shorter survival.

Case history: A 37-year-old female presented with loss of appetite & abdominal distension. CA 125 was 1888.5 IU/L. CECT showed a 15 mm-mass. DT was 126 days. Uptake was decreased on EOB-MRI. AFP/PIVKA-II was 72 mm. It (72 mm) was hyper-enhanced in early-phase hepatobiliary phase. PET-CT revealed FDG uptake. CA19-9 was 43.7U/mL. As ICC/CoCC diagnosis. He has remained recurrence-free for 1.5 years. Our other patient, a 58-year-old female, detected a mass during follow-up for NBNC hepatitis. It (72 mm) was hyper-enhanced in early-phase CECT, followed by washout. A CT from 22 months prior showed a 15 mm-mass. DT was 126 days. Uptake was decreased on EOB-MRI hepatobiliary phase. PET-CT revealed FDG uptake. AFP/PV/KAI-II were slightly elevated. She underwent hepatectomy under a diagnosis of hepatocellular carcinoma. Histologically, the tumor had necrosis and tubular structures of various sizes with apical membranes positive for EMA, indicating CoCC. Postoperative lymph node and bone metastases were found 2 and 13 months, respectively.

Conclusion: DT was prolonged in both patients as compared to previous report in ICC cases. This implies good outcomes. One had a well-differentiated, however, the other a mixed well to poorly-differentiated tumors reflecting marked clinicopathological differences. Diversity exists among CoCC cases.

Abstract Submission No. 200198

Reconsidering cholangiocarcinoma from two cases presenting with different characteristics

Akiko Saito1, Ayaka Gamo1, Yasuo Tanaka1, Yasushi Kojima1, Mikio Yanase1, Fuyuki Inagaki1, Norihiro Kokudo1, Hidemiki Miyazaki1, Masayuki Nakano2

1National Center for Global Health and Medicine Tokyo Japan, 2Tokyo Central Pathology Laboratory Tokyo Japan

Cholangiocarcinoma (CoCC) is small duct type intrahepatic cholangiocarcinoma (ICC) according to WHO classification. We experienced two patients with different clinicopathological findings, prompting us to reconsider CoCC characteristics.

Patients: A 76-year-old male with a mass on US, underwent CEUS demonstrating whole-tumor enhancement and washout within one minute. It (46 mm) showed arterial peripheral enhancement and equilibrium phase delayed enhancement on CECT. Retrospectively, the mass (6 mm) had appeared as arterio-portal shunt 9 years earlier. The tumor doubling time (DT) was 380 days. EOB-MRI showed decreased uptake in the hepatobiliary phase. CA19-9 was 43.7U/mL. As ICC/CoCC was suspected, partial hepatectomy was performed and yielded a CoCC diagnosis. He has remained recurrence-free for 1.5 years. Our other patient, a 58-year-old female, detected a mass during follow-up for NBNC hepatitis. It (72 mm) was hyper-enhanced in early-phase CECT, followed by washout. A CT from 22 months prior showed a 15 mm-mass. DT was 126 days. Uptake was decreased on EOB-MRI hepatobiliary phase. PET-CT revealed FDG uptake. AFP/PV/KAI-II were slightly elevated. She underwent hepatectomy under a diagnosis of hepatocellular carcinoma. Histologically, the tumor had necrosis and tubular structures of various sizes with apical membranes positive for EMA, indicating CoCC. Postoperative lymph node and bone metastases were found 2 and 13 months, respectively.

Conclusion: DT was prolonged in both patients as compared to previous report in ICC cases. This implies good outcomes. One had a well-differentiated, however, the other a mixed well to poorly-differentiated tumors reflecting marked clinicopathological differences. Diversity exists among CoCC cases.

EUS Role in Defining Endoscopic and Histopathological Spectrum of Liver Lesions - South Asian Study

Masood Karim1, Adeel Ur Rehman1, Om Parkash1, Zeeshan Uddin1

1Aga Khan University Hospital, karachi Karachi Pakistan

Introduction: Conventionally liver lesions sample are acquired by transabdominal ultrasound guided procedure. Currently EUS guided liver biopsies demonstrated better diagnostic yield with letter adverse event.

Aim: Aim of study to evaluate safety and diagnostic role of EUS in defining different endoscopic and histopathological spectrum of liver lesions in our region (South Asia).

Method: It is a descriptive study conducted at Endoscopy Suite, Aga Khan University Hospital from January 2021 to December 2023. All inpatient and outpatient with Liver lesion with or with organs involvement were included in study. Data were collected and analyzed using SPSS Version 22.

Results: Total 20 patients were included in the study. Majority of patients were male 15 (75%) while 5 (25%) were female. All patients were adult above 33 years ranging from 34 to 78 years. Main indications for EUS guided biopsies were pancreatic mass with Liver Lesions 7 (35%), Isolated liver lesion 4 (20%) and Porta hepatis mass with Liver Lesions 3 (15%). All procedures were done in conscious sedation and most of patient had ASA score II 13 (65%). In all procedures, 22G FNB needle with slow pull technique were used major of single pass 13 (65%), diagnostic yield was 100% with no sedation and procedure related complication.

Histopathology analysis revealed common findings were metastasis of pancreatic origin10 (50%) comprising of adenocarcinoma (35%) and NET (15), metastatic cholangiocarcinoma 3 (15%) and Isolated liver lesions 4 (20%) which includes HCC 2 (10%) and benign 2 (10%).

Conclusion: Our study concludes EUS guided liver lesion biopsies are safe with high diagnostic yield. Metastatic diseases comprising pancreatic adenocarcinoma is the commonest histological finding followed cholangiocarcinoma and hepatoma.

Abstract Submission No. 100075

Lower incidence of adverse liver outcomes and HCC in patients with chronic liver disease and HIV

Maurice Michel1,2, Hannes Hagström3-4, Linnea Widman3, Piotr Nowak3,5, Ying Shang5, Jörn M. Schattenberg1,2, Axel Wester5

1I. Department of Medicine, University Medical Center Mainz Mainz Germany, 2Metabolic Liver Research Program, I. Department of Medicine, University Medical Center Mainz Mainz Germany, 3Department of Medicine, Huddinge, Karolinska Institutet Stockholm Sweden, 4Unit of Hepatology, Department of Upper GI Diseases, Karolinska University Hospital Stockholm Sweden, 5Unit of Infectious Diseases, Karolinska University Hospital Stockholm Sweden

Background: People living with HIV (PLWH) show a high incidence of chronic liver disease (CLD). However, whether HIV is associated with major adverse liver outcomes (MALO) in patients with underlying CLD remains to be determined.

Methods: In this population-based cohort study, data were retrieved from the Swedish National Patient Register to identify PLWH and CLD (n=2,375) or CLD without HIV (n=144,346) between 1997 and 2020. The cumulative incidence of MALO was calculated while accounting for competing risks (non-MALO death). Incidence rates per 1000 person-years were compared between the exposure groups (HIV vs. no HIV) with Cox regression to estimate adjusted hazard ratios (HR) and their 95% confidence intervals (CIs).

Results: The incidence rate per 1000 person-years of MALO was lower in PLWH (5.1, 95% CI 4.2-6.1) compared to patients without HIV (13.1, 95% CI 12.9-13.3). This translated into an adjusted HR of 0.77 (95% CI 0.64-0.93), driven by a lower rate of hepatocellular carcinoma (adjusted HR=0.61, 95% CI 0.43-0.86). Consistent results were noted across a range of subgroup analyses. The 10-year cumulative incidence of MALO was lower in PLWH (5.0%, 95% CI 4.1-6.1) than in patients without HIV (10.9%, 95% CI 10.7-11.0).

Conclusion: Among patients with CLD, the risk of MALO was lower in PLWH compared to those without HIV, primarily due to a lower incidence of HCC. These results suggest that HIV is not associated with a higher risk of MALO.

Abstract Submission No. 100085

Genotype 4 HEV infection trigger the initiation and development of acute pancreatitis

Jian Wu1, Fen Huang2

1Department of Clinical Laboratory, The Affiliated Suzhou Hospital of Nanjing Medical University, Suzhou Municipal Hospital, Suzhou University Medical Center, 242 Guangji Road, Suzhou 215008, Jiangsu, China; Suzhou China, 2Medical School, Kunming University of Science and Technology, 727 Jing Ming South Road, Kunming, China; Kunming China

Background: The role of HEV infection in pancreatitis patients remains unclear.

Methods: 1000 eligible patients with AP, 1000 healthy controls (HCs) and 300 patients with AHE were enrolled. Rhesus macaques with HEV infection model was constructed to assess pancreatitis in rhesus macaques infected with HEV.

Results: The positive rates of anti-HEV IgG, anti-HEV IgM and HEV RNA in the AP patients were all significantly higher than HCs. With the increase of the severity of AP, the percentage of HEV infection also increased significantly. The percentage of patients with severe AP in the AP-AHE group was significantly higher than the AP group. Moreover, HEV infection was one of the main independent risk factors and owned the high predictive power for the outcome of AP. High level of HEV titre would prolong the recovery time. Both ISH and IHC showed that HEV replicates in the pancreas of rhesus macaques. HE staining showed that the structure of the pancreatic islets was damaged and the tissue was loose after 272 dpi of HEV infection. After 770 dpi, a large amount of hyperemia appeared in the pancreatic islets. Both IFA and quantitative analysis of CD45 and F4/80 showed rhesus macaques infected with HEV caused a large number of inflammatory cells in the pancreas. Quantitative detection of HEV RNA in the serum, liver, and pancreas of rhesus macaques revealed that the pancreas and liver had a comparable viral load.

Conclusions: HEV infection plays an important role in the occurrence, development and prognosis of AP.

Imprinted SARS-CoV-2 humoral immunity induces a high reinfection risk in cirrhotic patients

Qian Zhu¹, Hong Ren¹

¹Department of Infectious Diseases, Key Laboratory of Molecular Biology for Infectious Diseases (Ministry of Education), Institute for Viral Hepatitis, the Second Affiliated Hospital, Chongqing Medical University Chongqing China

Background: The potential risk and related mechanism of Omicron reinfection after BA.5 breakthrough infection (BTI) in cirrhotic patients remain unclear.

Methods: We collected peripheral blood samples from 32 cirrhotic patients with different SARS-CoV-2 vaccination history 9 to 31 days after BA.5 infection to evaluate the hybrid humoral immunity. Serum neutralizing activity against Omicron subvariants was examined by pseudo-virus neutralization assay. BA.5 specific B cell memory was evaluated by flow cytometry.

Results: Omicron BA.5 BTI elicited higher serum geometric mean titers (GMTs) against Wuhan-1 rather than BA.4/5 in cirrhotic patients with wildtype (WT)-based vaccination history regardless of 2-dose group and 3-dose group, but converse result was shown in unvaccinated patients. The serum GMTs against highly immune-evasive XBB.1.5 were lowest in all cirrhotic patients. In the 3-dose cohort, more than 80% of the BA.5 anti-receptor-binding domain (RBD)-binding memory B cells (MBCs) also bind to WT, indicating that BA.5 BTI mainly recalls cross-reactive MBCs elicited by WT-based vaccine, but rarely produces BA.5 specific MBCs. Besides, when compared with 2-dose group, cirrhotic patients with 3-dose vaccination did not show significant increased serum GMTs against BA.4/5 and XBB.1.5, consistent with the frequencies of BA.5 specific MBCs and plasmablasts (PBs).

Conclusions: We reported the imprinted SARS-CoV-2 humoral immunity shaped by WT-vaccination in cirrhotic patients for the first time, which predicts their high risk of reinfection in next potential wave including XBB.1.5. Our results supported the consideration of incorporating the Omicron variants into subsequent vaccine design and performing more studies of alleviating immune imprinting in this vulnerable population.

**An Immunocompetent Mongolian Gerbil Model for Hepatitis E Virus Genotype 1 Infection**

Tianxu Liu1, Lin Wang1

1Peking University Beijing China

**BACKGROUND & AIMS:** Hepatitis E virus (HEV), primarily genotype 1 (HEV-1) accounts for approximately 20.1 million HEV infections, 44000 deaths, and 3000 stillbirths annually. Like HAV, HBV, HCV and HDV, current evidence demonstrated that HEV-1 only infects humans and no immunocompetent small animal model exists for the study of HEV-1 infection. We evaluated if Mongolian gerbils could serve as an alternative.

**Methods:** Mongolian gerbils were used for infection experiments with HEV-1 and HEV-3. HEV infection parameters, including HEV RNA, anti-HEV, antigen, liver function test and histopathology were determined.

**Results:** We adapted a clinical isolate of HEV-1 by serial passages in the feces of aged male Mongolian gerbils. The resulting gerbil-adapted strain at passage 3 induce robust acute HEV infection characterized by stable fecal virus shedding, elevated liver enzymes, liver histopathological changes and seroconversion to anti-HEV. HEV-1-infected pregnant gerbils showed vertical transmission. HEV RNA or antigens were detected in the liver, kidney, intestine, placenta, testis and the neonates/fetus liver samples. Intrahepatic transcriptomic analysis indicated activation of innate immunity. Tumor growths in both liver and intestinal tissues. Tendency of elevation in serum aminotransferases was observed in the liver and intestinal tissues. Submucosal inflammation was partly observed in the intestinal tissues. Tendency of elevation in serum aminotransferases was observed.

**Conclusions:** This HEV-1 infection gerbil model should be of value in investigating hepatitis E immunopathogenesis and evaluating vaccines and antivirals against HEV.

---

**Epigallocatechin-3-gallate (EGCG), a polyphenolic compound found in green tea, has demonstrated anti-pathogenic potential against various infectious agents. This study aimed to elucidate the anti-pathogenic mechanisms underlying EGCG’s efficacy against the pathogenesis of C. burnetii in granulomatous hepatitis using a bioinformatics model. A bioinformatics approach employing STITCH v.5.0 program was used to identify the protein targets and predict their functional role and virulence properties. EGCG was found to target ten important proteins of C. burnetii, including dihydrolipoyl dehydrogenase (lpdA), dihydrofolate reductase (folA), peptidyl-prolyl cis-trans isomerase surA (CBU_1980), DNA mismatch repair protein (mutL), (3R)-hydroxymyristoyl-ACP dehydratase (fabZ), aspartate aminotransferase (aspB), polyketide synthase (CBU_0788), methylated-DNA-[protein]-cysteine S-methyltransferase (ogt), hypothetical protein (1415), and ABC transporter permease (CBU_0933). Specifically, those identified virulence factors are essential in the survival of C. burnetii. It can be concluded that the anti-pathogenic mechanism of EGCG against C. burnetii in granulomatous hepatitis is through blocking several virulence factors associated with bacterial cell survival and metabolisms. However, the findings of this bioinformatics study need to be further proven and validated using in vitro and in vivo experiments.

---

**In vitro and in vivo hepatitis A virus infection models for anti-HAV drugs screening**

Reina Sasaki-Tanaka1, Tatsuo Kanda1, Noriko Nakajima1, Hiroaki Okamoto2

1Department of Medicine, Nihon University School of Medicine Tokyo Japan, 2Division of Virology, Department of Infection and Immunity, Jichi Medical University School of Medicine Tochigi Japan

**Aims:** Developing a new in vivo HAV infection mouse model.

**Methods:** 1) Human hepatoma cell line Huh7 or HepG2 were infected with HAV GT-IB HM175 or GT-IIIA HA11-1299 strain and then transplanted into the back of nude mice as xenografts. 2) HAV RNA were measured by real-time RT-PCR in feces, sera, liver and intestinal tissues and tumors of the mice. 3) Tissues were stained by H&E. 4) Serum aminotransferases were measured by ELISA.

**Results:** 1) No difference in the bodyweight of HAV infected and uninfected mice. Mice transplanted with HepG2 cells and mice transplanted with Huh7 cells were sacrificed after 13 days and after 32 days of transplantation, respectively. 2) Mice transplanted with HepG2 cells of HAV infection - HAV RNA detected in tumors only. 3) Mice transplanted with Huh7 cells of HAV GT-IB HM175 infection - No tumor and no HAV RNA detected. 4) Mice transplanted with Huh7 cells of HAV GT-IIIA HA11-1299 infection - HAV RNA detected in feces, sera, liver and intestinal tissues and tumor. Hepatic necroinflammation was observed in the liver. Submucosal inflammation was partly observed in the intestinal tissues. Tendency of elevation in serum aminotransferases.

**Discussion and Conclusion:** Mice transplanted with Huh7 of HAV GT-IIIA HA11-1299 infection seems useful as an in vitro HAV infection model for anti-HAV drugs screening. In this model, inflammation was histopathologically observed in the liver and intestinal tissues where HAV RNA was detected. We developed a xenograft mouse model with HAV GT-IIIA HA11-1299 infection.

**Plasma Exchange as a rescue therapy for severe prolonged cholestasis in Acute Viral Hepatitis**

Sunil Taneya1, Ganesh C P1, Muhammad Uwais Ashraf1, Sahaj Rath1, Arka De1, Nipun Verma1, Madhumita Premkumar1, Rekha Hans2, Ratti Ram Sharma2, Ajay Duseja1

1Department of Hepatology, Postgraduate Institute of Medical Education & Research Chandigarh India, 2Department of Transfusion Medicine, Postgraduate Institute of Medical Education & Research Chandigarh India

**Background:** Most cases of acute viral hepatitis (AVH) resolve within weeks; however, a subset of patients develop severe prolonged cholestasis with disabling symptoms. This retrospective study aimed to investigate the etiology, management, and outcomes in patients of AVH complicated by prolonged cholestasis.

**Methods:** A retrospective analysis of 50 patients admitted with AVH complicated with prolonged cholestasis was done. Data was collected from medical records; clinical features, laboratory investigations, treatment and outcomes were analyzed.

**Results:** 50 patients, majority young males 88%(n=44) with mean age of 23.4±4.5 years were analyzed. Hepatitis A virus was the cause of AVH in forty-seven (94%) patients. Common symptoms included severe pruritis in 96% (n=48), disturbed sleep in 90% (n=45) and dry
cough in 70% (n=35). At the time of presentation, mean bilirubin was 30.3±5.9mg/dL, serum alkaline phosphatase (SAP) level was 166.3±47.2 IU/L, AST was 136±58.6 IU/L and ALT of 152.4±76.3IU/L. The mean bile acid concentration was 197.8±31.2 mg/dL. All patients received oral anti-pruritic medications for an average duration of 34.3 days. Thirty-Seven (74%) patients underwent standard volume Plasma Exchange (PLEX) with a range of 1-5 sessions. Twenty-Five (50%) patients received a short course of oral steroids (20 mg) after undergoing plasma exchange. Six (12%) patients received only steroids. Group that received combined PLEX followed by steroids exhibited significant improvements in symptoms, bilirubin and bile acids at 4 weeks (p=0.001) compared to the other groups. **Conclusion:** PLEX followed by oral steroids is a novel strategy for managing severe prolonged cholestasis with incapacitating symptoms in AVH.

**Small intestinal bacterial overgrowth in liver disease: Do jejunal cultures predict outcome?**

Moinak Sen Sarma1, Chinnoy Sahu1, Uday Ghoshal2, Ujjwala Ghoshal2, Ujjal Poddar1, Anshu Srivastava1, Amrita Mathias1

1Dept of Pediatric Gastroenterology, Sanjay Gandhi Postgraduate Institute of Medical Sciences Lucknow India, 2Dept of Gastroenterology, Sanjay Gandhi Postgraduate Institute of Medical Sciences Lucknow India, 3Dept of Microbiology, Sanjay Gandhi Postgraduate Institute of Medical Sciences Lucknow India

**Introduction:** There is limited data on bacterial translocation and small intestinal bacterial overgrowth (SIBO) in pediatric cirrhosis. We aimed to evaluate and interrelate the endotoxin assay, breath test and jejunal cultures in cirrhosis.

**Methodology:** A prospective study enrolled cirrhotic children for jejunoscopy, glucose hydrogen-breath test (GHBT, normal <12ppm above baseline), serum and ascitic lipopolysaccharide-binding protein (LBP, normal <5mcg/mL). Jejunal culture (aerobic and anaerobic media) antibiotic sensitivity (Kirby-Bauer disc diffusion method) and resistance genes (conventional polymerase chain reaction) were assessed. The median, minimum, and maximum areas under curve of GHBT were estimated using Ghoshal BreathCalc (Patent appl.No. 202111029055). Extrahepatic portal-venous obstruction patients were controls.

**Results:** Of the 56 cirrhotic children (pediatric end-stage liver disease score, PELD 15.4±4.3, 18 (32%) had evidence of ascitic fluid infection (AFI) with AF-LBP 7.6±3.3 mcg/mL (fig1). Twelve of 21 (57%) cirrhotics with positive jejunal culture had one or more morbidity outcomes (hospital readmission, systemic infection, renal dysfunction, recurrent AFI, persistent hyponatremia and relative adrenal insufficiency) over the next 6 months. Of these twelve, six had high AF-LBP (18±2.7), serum LBP (33±8.7) and jejunal culture multidrug antibiotic resistance (mecA, NDM-1, mec-1, SHV-1, NDM-1 genes). All six patients died in next 8 (3-12) months. Serum LBP correlated with absolute neutrophil count (r=0.77, p=0.01) and pediatric end-stage liver disease (PELD) score (r=0.87, p<0.03). Serum LBP cut-off >7.8 mcg/mL (AU/ROC 89%, sensitivity 88%, specificity 64%, p=0.02) predicted short-term morbidity events. All ten patients with AF-LBP >10 mcg/mL had renal dysfunction.

**Conclusions:** Jejunal culture-positive SIBO in cirrhotics predicts short-term morbidity outcomes.

**O-0754**

**Global, regional, and national burdens of HEV from 1990 to 2019 and forecasted incidence in 2030**

Yu-Chen Fan1,2, Bai-Yun Wu1,2, Jing Zuo1,2, Qi An1,2, Yu-Xin Tian3, Ruo-Xi Jia3, Kai Wang3

1Department of Hepatology, Qilu Hospital of Shandong University Jinan China, 2Institute of Hepatology, Shandong University Jinan China, 3Department of Infectious Diseases, The affiliated Hospital of Qingdao University Qingdao China

**Aim:** Hepatitis E virus (HEV) is the emerging cause of viral hepatitis. Here, we reported the trends of HEV burden at the global, regional, and national levels from 1990 to 2019, and predicted the forecasted incidence in 2030.

**Methods:** Using the data from the Global Burden of Diseases (GBD) 2019, we performed the trend analysis to report the incidence of HEV infection, disability-adjusted life years (DALYs), incidence per 100,000 population, average annual percentage changes (AAPCs), and social development index (SDI). Connection point regression analysis was performed to identify the years with the most significant changes in global trends. Furthermore, we predicted the incidence of HEV infection in 2030 using Bayesian age-period-cohort analysis.

**Results:** The incidence of global HEV infection decreased from 304.3 per 100 000 population in 1990 to 251.63 in 2019 with the AAPC as 0.13. The specific years for significant decrease of HEV incidence were 2006, 2009, 2014 and 2017. Regionally, Western Sub-Saharan Africa had the highest incidence and Southern Sub-Saharan Africa had the largest increase of incidence between 1990 and 2019. From 1990 to 2019, the highest incidence and DALYs rate of HEV infection was Low-middle SDI countries, while Middle SDI countries had the largest decrease in incidence and the High-middle SDI countries had the largest decline in DALY’s. In 2030, the predicted global incidence of HEV infection is 275.34 per 100 000 population.

**Conclusion:** Global HEV incidence decreased between 1990 and 2019 but the incidences of individual regions and countries are still increasing year by year.

**PERCUTANEOUS TREATMENT OF HYDATID CYSTS WITH THE ORMECI TECHNIQUE**

Necati Ormeci1, Ozgun Omer ASILLER2, Ayhan Parmaks3, Cagdas Kalkan2, Ercan Ustuner4, Ahmet Altilt2, Hakan Erdem4

1Istanbul Health and Technology University Istanbul Turkey, 2Ankara University Medical School, Department of Anesthesiology and Reanimation Ankara Turkey, 3Ministry of Health, Ankara City Hospital Ankara Turkey, 4Ankara University Medical School, Department of Radiology Ankara Turkey, 5Turkish Health Sciences University, Guilhane School of Medicine, Department of Infectious Diseases and Clinical Microbiology Ankara Turkey, 6ID-IRI Lead Coordinator Ankara Turkey

**Aim:** This study is to analyze the efficacy of the ÖRMECİ technique used in the treatment of Hydatid cysts.

**Methods:** This is a retrospective cohort study. Patients with Hydatid cysts who presented to the Ankara University School of Medicine, Department of Gastroenterology since 1991 were included. Patients with WHO-CE types 1, 2, 3A-3B live cysts who were treated...
percutaneously at least once and followed-up after a minimum of six months were analyzed.

**Results:** A total of 1556 cystic lesions in 1035 patients have been presented to our department since 1991. 544 live HCs in 479 patients were treated with the RMECI technique. The mean follow-up time was 59.29 months for females and 57.18 for males. The overall clinical success rate of all treated cysts with the RMECI technique was 94.5%. After the treatment, a statistically significant decrease was found in all WHO-CE cyst types in terms of cyst sizes (p < 0.001 for all). Mortality, abscess and fistula formation, sclerosing cholangitis, and drug toxicities were not detected. Only two patients experienced reversible anaphylaxis during the treatment among 544 cysts (0.36%).

**Conclusion:** Hydatid cysts can be treated percutaneously by the RMECI technique with a high success rate for WHO-CE Type 1, 2, and 3B. The RMECI technique is an economic, simple, cheap, repeatable outpatient procedure. It can be chosen as the first-line therapeutic modality in suitable patients with Hydatid cysts.

**Hepatitis E virus infects human testicular tissue and Sertoli cells**

**Tianxu Liu1, Lin Wang1**

1Peking University Beijing China

Globally, hepatitis E virus (HEV) infections are prevalent. The finding of high viral loads and persistent viral shedding in ejaculate suggests that HEV replicates within the human male genital tract, but its target organ is unknown and appropriate models are lacking. We aimed to determine the HEV tropism in human testis and its potential influence on male reproductive health. We conducted ex vivo culture of human testis explants and in vitro culture of primary human Sertoli cells. Clinically derived HEV genotype 1 (HEV1) and HEV3 virions, as well as rat derived HEV-C1, were used for inoculation. Transcriptomic analysis was performed on testis tissues collected from tacrolimus-treated rabbits with chronic HEV3 infection. Our findings reveal that HEV3, but not HEV1 or HEV-C1, can replicate in human testis explants and primary human Sertoli cells. Tacrolimus treatment significantly enhanced the replication efficiency of HEV3 in testis explants and enabled successful HEV1 infection in Sertoli cells. HEV3 infection disrupted the secretion of several soluble factors and altered the cytokine microenvironment within primary human Sertoli cells. Finally, intratesticular transcriptomic analysis of immunocompromised rabbits with chronic HEV infection indicated a downregulation of genes associated with spermatogenesis. HEV can infect the human testicular tissues and Sertoli cells, with increased replication efficiency when exposed to tacrolimus treatment. These findings shed light on how HEV may persist in ejaculate of patients with chronic hepatitis E and provide valuable ex vivo tool for studying countermeasures.

**Hepatic Tuberculoma Masquerading as Hepatocellular Carcinoma: A Case Report**

**Laurence Laurel1, Janelle Gagelonia1, Marceliano Aquino Jr.1**

1St. Luke's Medical Center - Global City Taguig Philippines

Hepatic Tuberculoma, a rarely-seen tuberculosis manifestation, presents a complex challenge to gastroenterologists due to its diverse clinical presentations. This case report sheds light on a unique instance of liver tuberculosis in a region grappling with a high prevalence of HBV. In this particular case, it not only mimicked Hepatocellular Carcinoma but also exhibited symptoms characteristic of Charcot’s Triad. Our patient, a 35-year-old male, initially presented with a one-week history of right upper quadrant abdominal pain, jaundice, and fever. Initially suspected as Acute Cholangitis, further investigation through MRCP revealed a 2x2cm hypointense ovoid lesion in segment 5. This diagnostic puzzle led to a liver biopsy to rule out Hepatocellular Carcinoma. To our astonishment, the biopsy showed clusters of epithelial cells intermingled with poorly formed caseating granulomas alongside benign hepatocytes. Additionally, MTB-PCR analysis of tissue core fragments yielded positive to Mycobacterium tuberculosis. Subsequently, the patient commenced anti-koch’s therapy, and at the time of this report, is on his third month of treatment with a remarkable resolution of the initial symptoms.

In conclusion, this case underscores the critical consideration of Hepatic Tuberculoma in the differential diagnosis of liver lesions, particularly in regions with a high HBV prevalence. It is vital to have a heightened index of suspicion, comprehensive histopathology confirmation to differentiate Hepatic Tuberculoma from Hepatocellular Carcinoma. This report contributes to the evolving body of literature concerning the distinctive presentations of tuberculosis. Timely diagnosis and prompt initiation of anti-koch’s therapy play a pivotal role in achieving a favorable clinical outcome in such cases.

**We did not look for it because it was everywhere: The Ubiquitous presence unveiled**

**Srijaya Sreesh1, Sreekumar Sivadasan1, Aditya Verma1, Nuzil Moopan1, Jithin John1, Jesse Skaria1, Jacob Raja AS1, Rashid KK2, Ann Mary George3, Krishnadas Devadas1**

1Department of Medical Gastroenterology Thiruvananthapuram India

49 year old homemaker presented with c/o Jaundice for 2 weeks, Menorrhagia for 1 week and Generalised pruritus for 2 days

Past History - 8 months back she received Ormiloxifene for 3 months for dysmenorrhea related to uterine fibroid

Examination revealed icterus, pedal edema, skin excorrision

Baseline investigation - HB-5.6; LFTI TB/DB - 10.9/5.9 mg/dl SGOT/SGPT-761/283 U/L ; TP/Alb-5.2/2.4 g/L ; ALP- 127U/L GGT-29.5(50)U/L; INR- 1.63.

USG abdomen showed minimal ascites and mild coarsening of liver echotexture.

Ascitic fluid examination revealed high SAAG low-protein ascites without evidence of infection. Etiological evaluation of liver dysfunction done twice-no clue.

Clinical progression and treatment- Due to onset of encephalopathy, she was planned for superurgent liver transplantation. Due to non-availability of a matching donor, she underwent 3 cycles of Plasma-Exchange as bridge to transplantation. Trans-jugular liver biopsy (TJLB)-histopathology report was suggestive of Acute hepatitis with hepato-canalicular bilirubinostasis, and mild steatosis. Extended investigations revealed HAV-RNA PCR positive. Even though HAV is endemic in India with >95% IgG-HAV antibody positivity among adults, we started Ribavirin as we were left with no other choice. Due to high suspicion of false positivity, HCV RNA-PCR was repeated 2 days later which confirmed the earlier positive report. Meanwhile there was dramatic response to Ribavirin in 2 weeks with near normalisation of LFT and complete resolution of ascites and encephalopathy

Take home Message- Time to think about occult Hepatitis A with Flare precipitated by the immunomodulatory effects of Ormiloxifene,
Gas Sonogram within Ablation Zone: A Strong Indicator of Post-ablation Infection in Liver Malignancy

Rui Zhang¹, Di Li¹, Ming Xu¹

¹Department of Medical Ultrasonics, the First Affiliated Hospital, Sun Yat-Sen University Guangzhou City China

Background: Patients with gas sonogram within ablation zone are more likely to develop post-ablation infections, but few researches focused on the relationship between the unique image and infection. This study aimed to explore the relationship between ‘gas sonogram’ within the ablation zone and post-ablation infection in liver malignancies.

Methods: This retrospective study reviewed patients between November 2011 and November 2021 who underwent percutaneous thermal ablation in liver malignancies. All patients with ‘gas sonogram’ within ablation zone were included as the case group (n=57), and and two treatment date-matched control without gas sonogram were randomly selected for each case, following a nested case-control design. Gas sonogram was then divided into three classes according to ultrasound imaging.

Results: The post-ablation infection rate and severe infection rate in case group were significantly higher (54.4% (31/57) vs 6.1% (7/114), 26.3% (15/57) vs 0.9% (1/114)), while the hospital stay was significantly prolonged (5 days vs 2 days). No statistically significant difference was showed in recurrence and LTP rate. In case group, gas class III was a more dangerous type and strongly indicated infection. Multivariable logistic regression showed the independent factors for gas sonogram were prior biliary intervention (OR=6.249), cancer type (OR=2.086), and proximity to bile ducts (OR=2.136), and the independent predictor for gas class III was gas range (OR=1.778).

Conclusions: Patients with ‘gas sonogram’ within ablation zone after thermal ablation in liver malignancies were prone to infection, especially gas Class III. Vigilance is required for these patients including early prophylactic antibiotic therapy and local catheter drainage should be instituted.

Hepatobiliary Tuberculosis Mimicking Hepatic Malignancy

Hsin-Yi Chen¹, Jui-Ting Hu¹

¹Division of Digestive Medicine, Cathay General Hospital, Taipei Taipei Taiwan

Background: Hepatobiliary tuberculosis (HBTB) is a rare form of tuberculosis (TB) infection, and frequently misguided into the diagnosis of hepatic malignancy.

Methods: Clinical data from two patients were collected from medical records. The essential features leading to the diagnosis of HBTB and TB infection, and misdiagnosis of HBTB were analyzed.

Results: Both cases presented with abdominal fullness, body weight loss, low-grade fever, and initial medical imaging studies leading to suspicion of hepatic malignancy, but pathological findings of granulomatous inflammation with caseous necrosis leading to the diagnosis of HBTB. One case had axillary lymph node TB culture showing mycobacterium tuberculosis complex. In one case, hepatic mass regressed completely. The other case had resolved hepatic infiltrative change, but persistent hepatic segmental atrophy.

Conclusion: The clinical and radiological features of HBTB remain the great masquerader of hepatic malignancy, sometimes leading to unnecessary surgery. Diagnosis usually requires pathological proof, but once the diagnosis is confirmed, response to therapy is usually optimum.

Prognostic role of serum VEGF and HGF post SBRT in advanced hepatocellular carcinoma

Prabhiyoti Pahwa1, Deepti Sharma1, Pushpa Yadav1, Sherin S Thomas1, Sandhya Hora1, Preedia B E1, Gayatri Ramakrishna1, Shiv K Sarin4, Nirupama Trehanpati1

1Department of Molecular and Cellular Medicine, Institute of Liver and Biliary Sciences Delhi India, 2Department of Oncology, Institute of Liver and Biliary Sciences Delhi India, 3Department of Biochemistry, Institute of Liver and Biliary Sciences Delhi India, 4Department of Hepatology, Institute of Liver and Biliary Sciences Delhi India

Background: Stereotactic body radiation therapy (SBRT) is a treatment option for hepatocellular carcinoma (HCC) patients who are ineligible for other local therapies. An early diagnosis is important for improving the survival rate of patients. Other than AFP and PIVKA II, markers for tumor progression, prognosis and recurrence are needed.

Methods: HCC patients (n=18) were subjected to SBRT dose of 30-50Gy in 5 fractions and serum level of HGF, VEGF and EGF were analysed using enzyme-linked immunosassay before SBRT, at the completion of SBRT and 30 days post SBRT. Cumulative survival rates were calculated using the Kaplan-Meier method and were compared using the log-rank test.

Results: Total of 18 patients were analysed over a median follow up period of 10 months (05-27 months). In patients, the median overall survival was 13 months (95% confidence interval [CI], 5-20.9) with SBRT. The 12 months local control and progression free (PFS) was 80% and 50% respectively. Patients with raised PIVKA-II at baseline and post SBRT showed increased concentrations of VEGF and EGF (Fig B-C). Patients with increased VEGF and HGF at 30 days post SBRT had poor PFS (Fig D). The median progression free survival (mPFS) was 6 months vs. 14 months in patients with increase in VEGF (Fig D). Similarly, mPFS in patients with increase in HGF was 9 months as compared to 14 months post SBRT.

Conclusions: Along with PIVKA II, HGF, EGF and VEGF can be used as prognostic markers to predict the OS, PFS and metastasis in HCC patients.

Abstract Submission No. 101947
O-0763
Background: Liver parenchymal transection is the most important process in liver resection. Current study shows our clamp-crushing technique for robot-assisted liver resection (RLR) and evaluates its perioperative outcomes.

Methods: The da Vinci Surgical System Xi robot is used for RLR. During clamp-crushing technique, the right hand uses a Maryland bipolar connected to the Force Triad Macro mode on arm No.3 or No.4. The EndoWrist One Suction Irrigator is used on arm No.1 to perform all suction and irrigation with the surgeon’s left hand. During this solo-surgery, after crushing with the Maryland bipolar in the right hand, suction is performed with the left hand. Small vessels are cauterized and separated with the Maryland bipolar, and vessels larger than 3 mm in diameter are clipped. When bleeding occurs, hemostasis could be efficiently achieved by using a bipolar system while suction and irrigation. A good surgical field of view could be maintained by alternately using suction and Maryland bipolar to hold up or down the liver dissection plane.

Results: From August 2022 to December 2023, a total of 17 patients underwent RLR. Median total operation time was 384 min, median console time was 305 min and median blood loss was 50 ml. There were no CD≥3 postoperative complications, and median hospital stay was 10 days.

Conclusion: RLR could be safely performed by a clamp-crushing technique using EndoWrist One Suction Irrigator.

Robot-assisted liver resection guided by ICG fluorescence imaging and artificial intelligence

Kazuhiro Matsuda1, Takeshi Aoki1, Nao Kobayashi2, Yoshihiko Tashiro1, Tomokazu Kusano1, Kodai Tomioka1, Shodai Nagashii1, Kazuhiro Saito1, Tatsuya Yamazaki1, Yukari Shinohara1, Takahito Hirai1, Hideki Shibata1, Yuta Enami1, Koji Nogaki1, Akira Fujimori1

1Department of Gastroenterological and General Surgery, Showa University Tokyo Japan, 2Anaut.Inc. Tokyo Japan

Background: Although the number of robot-assisted liver surgery (RALS) has increased in recent years, the lack of haptic feedback remains an issue. Indocyanine green (ICG) fluorescence imaging has proven to be a high potential navigation tool and may be a way to overcome the limitation. Furthermore, we have developed a surgical support artificial intelligence (AI) system to improve the recognition accuracy of vascular structures. This study aimed to investigate the feasibility and clinical application of ICG fluorescence imaging and AI to guide RALS.

Methods: 11 patients who underwent RALS with fluorescence imaging for liver tumor were included. The da Vinci Xi system’s Firefly mode was used to observe fluorescence, liver transection was performed under IOUS and ICG fluorescence guidance. The AI algorithm was evaluated at Anaut Inc.

Results: The subjects included 4 hepatocellular carcinoma, 6 colorectal liver metastasis, and one focal nodular hyperplasia. The mean operative time and blood loss was 354 minutes and 105g, there were no postoperative complications and mortality. In all cases, ICG fluorescence imaging successfully identified tumor localization and aiding in liver transection guidance. The pathological findings of all tumors indicated negative margins, defined as R0. The AI model accurately recognized vascular structures of any size in real-time and indocyanine green fluorescent imaging without visual discrepancies.

Conclusion: The ICG fluorescence imaging is a promising navigational tool, that can potentially overcome the limitations of RALS. Although this AI system is currently limited to preclinical application, these results may support the realization of more accurate real-time navigation.

Robot-assisted Limited Anatomic Liver Resection: A Report on the Current Status

Taiga Wakabayashi1, Yusuke Nie1, Junichi Sakamoto1, Shohei Fujita2, Chie Hagiwara2, Atsuko Itatsu2, Nobuhiko Okamoto1, Kenji Omura1, Go Wakabayashi1

1Ageo Central General Hospital Ageo-shi Japan

Background: Since the inclusion of robot-assisted liver resection (R-LR) in insurance coverage, the number of cases has gradually increased in Japan. This report outlines the current status of minimally invasive liver resection (MI-LR) at a leading robotic hospital in Japan.

Methods: In our institution, the Glissonean approach (GA) and indocyanine green negative staining (ICG-NS) are employed as fundamental techniques in minimally invasive anatomic resections (MI-AR). We aimed to analyze long-term outcomes of MI-AR and describe our approach for R-LR.

Results: Among 112 patients undergoing laparoscopic AR, the 5-year OS rates were 73% for hepatocellular carcinoma (HCC) and 60% for colorectal liver metastasis (CRLM). Of 42 R-LR cases (December 2021 to December 2023), 24 involved anatomic liver resection, 18 involved partial resection. Operative time averaged 384 minutes, blood loss 358ml, complications (≥Calvien-Dindo IIIa) occurred in 7 cases but were successfully treated. The average postoperative hospital stay was 14 days.

Conclusion: MI-AR exhibits favorable oncologic outcomes for HCC and CRLM. R-LR’s advantages lie in its flexible approach to Glissonean pedicle and vessels due to multi-joint functionality. Ongoing improvements in near-infrared light cameras and liver transection devices anticipate the safer implementation of R-LR.

Robotic surgery will be the standard approach to highly complex minimally invasive liver resection

Yutaro Kato1,2, Hiroyuki Kato1, Masayuki Kojima2, Takeshi Takahara2, Koichi Suda2, Atsushi Sugio2, Ichiro Uyama2, Akihiko Horiguchi1

1Department of Surgery, Bantane Hospital, Fujita Health University Nagoya Japan, 2Department of Surgery, Fujita Health University Toyoake Japan

Background: We have standardized surgical techniques of minimally invasive complex anatomic liver resection (MICAR) by extrahepatic Glissonian approach and hepatic vein root-at first cranial-to-caudal parenchymal dissection, based on Laennec’s capsule.

Methods: We performed 260 MICAR including 3 trisectionectomies, 58 hemihepatectomies, 4 bisectionectomies, 70 monosectionectomies and 125 segmentectomies (laparoscopic: LCAR 180; robotic: RCAR 80) at our institution. Indications were HCC (n=151), metastatic tumors (n=73), intrahepatic cholangiocarcinoma (n=13) and others (n=23). Posterolateral lesions were resected in 170 cases (65.4%). Repeat hepatectomies and reconstructive procedures were performed in 40 (15.4%) and 8 (3.1%) cases, respectively.
Results: In the entire MICAR cohort, the median operative time was 593 min and blood loss was 246g. Open conversion, major morbidity, bile leak/collection and 90-day mortality were 3.5%, 9%, 6.5% and 0.4%, respectively. Between propensity score-matched cohorts (64:64), compared to LCAR, RCAR had a lower rate of bile leak (1.6% vs. 11.1%, P=0.028), with comparable operative time, blood loss, conversion rate, morbidity, mortality and hospital stay. In MICAR for posterosuperior lesions and repeat hepatectomy, RCAR, which had worse tumor and procedural backgrounds than LCAR, still had comparable outcomes with LCAR. Reconstructive procedures were highly difficult laparoscopically, and no reconstruction-related complications were observed in RCAR. Postoperative long-term outcomes in newly developed HCC were comparable between LCAR (n=90) and RCAR (n=26).

Conclusions: Robotics may potentially improve safety of MICAR by technical dexterity, particularly for posterosuperior lesions, redo hepatectomy and reconstructive procedures, with comparable long-term outcomes in HCC with laparoscopic surgery. Robotic surgery will be the standard approach to MICAR.

Long-Term Outcomes of Robotic Surgery for Initial Liver Resection of Colorectal Liver Metastases

Hideaki Iwama1, Takeshi Takahara1, Satoshi Miil2, Akihiro Nishimura1, Takuya Mizumoto1, Yuichiro Uchida1, Masayuki Kojima1, Ichiro Uyama1, Koichi Suda1
1Fujita Health University Toyoake Japan

Background: Robotic surgery is becoming increasingly popular for liver resection, and although there are some reports on the short-term outcomes, there are few reports on the long-term outcomes for malignant tumors.

Methods: We compared the long-term outcomes of initial liver resection for colorectal liver metastases performed at our hospital during the 8-year period from 2010 to 2017 by dividing the patients into three groups: open, laparoscopic, and robotic surgery groups.

Results: There were 200 patients who underwent initial liver resection, 132 underwent open, 32 laparoscopic, and 15 robotic surgery. The number of cases of anatomic systematic resection was 90 (68.2%), 17 (53.1%) and 6 (40.0%), respectively, with more systematic resection cases in the open surgery group (p=0.015). The median and interquartile range of Beppu’s Nomogram Score (BNS) were 10 (6-15), 7 (4-10), and 4 (3-7), with higher BNS in the open surgery group (p=0.0001).

The long-term outcomes of 5-year and 10-year survival rates were 53.5% and 33.5% in the open group, 67.4% and 51.4% in the laparoscopic group, 53.5% and 44.4% in the robotic group, respectively, with no statistically significant difference (p=0.12).

Conclusion: This study did not show any superiority of robotic surgery in long-term outcomes.

Inventions of robot-assisted laparoscopic liver resection in our department

Yoichi Kawano1, 2, Keisuke Minaminmura1, Yukio Ooshiro2, Tetsuya Shimizu1, Akira Matshita1, Junji Ueda1, Takahiro Murokawa1, Yuto Aoki2, Takashi Ohno1, Akira Hamaguchi1, Yoshiharu Nakamura2, Hiroshi Yoshida1
1Department of Surgery, Nippon Medical School Tokyo Japan, 2Department of Surgery, Nippon Medical School Chiba Hokusoh Hospital Chiba Japan

Introduction: Robot-assisted surgery (RAS) for the liver resection in Japan has just been covered by insurance in 2022, and there is no robot-specific energy device that can be used laparoscopic liver resection, so there are Kanck & Pitfalls. We report on the innovations for it in the RAS in our department.

Results: RAS partial hepatectomy (PH) started in January 2023. 16 cases (11males, 5female), median age 60years (47-83), primary disease: colorectal cancer liver metastases 6, HCC 4, FNH 2, liver cyst 2, hemangioma 1, portal vein hepatic vein fistula 1, median operation time: 388.5min (233-580), median blood loss: ml (0-1020(including ascites)), Median postoperative discharge: days 6(5-12), C-D classification II or higher: 1 (cholecystitis C-D II).

Methods: RAS-PH in our department is performed by the clamp crush method using Meryland forceps. The most important factors are stable surgical field development and adequate tension on the hepatic transection plane using endoloop, organ retractor and thread suture traction which we named “parachute traction”. In addition, continuous drip-ping of saline through the CV catheter increases hemostasis ability with saline enhanced coagulation and it allows identification of the bleeding point. Continuous aspiration with SECURE and atom tube, and the use of folded gauze called “Benz gauze” are also very useful.

Conclusion: The following innovations have been developed, the tension at the hepatic transection plane, short pitch clamp crush method, saline enhanced coagulation and moisture control of the transection plane.
Impact of preoperative infection on the outcomes of liver transplant recipients

Ze Xiang1, 2, Yisu Song1, 2, Jiarui Li1, Xuyong Wei1, Jiayin Yang1, Yang Yang1, Shusen Zheng1, Xiao Xu1, 5, 7

1Zhejiang University School of Medicine Hangzhou China, 2Key Laboratory of Integrated Oncology and Intelligent Medicine of Zhejiang Province Hangzhou China, 3West China Hospital of Sichuan University Chengdu China, 4The Third Affiliated Hospital, Sun Yat-sen University Guangzhou China, 5NHC Key Laboratory of Combined Multi-organ Transplantation Hangzhou China, 6Shulan (Hangzhou) Hospital, Zhejiang Shuren University School of Medicine Hangzhou China, 7National Center for Healthcare Quality Management in Liver Transplant Hangzhou China

Background: Impact of preoperative infection on liver transplantation (LT) needs further investigation.

Methods: From January 1, 2015 to December 31, 2022, 24,122 eligible patients receiving LT were enrolled from the China Liver Transplant Registry database. The outcomes of LT were compared after using the propensity score-matched analysis.

Results: Compared to patients without preoperative infection, those with preoperative infection were more likely to have effusion, infection (both P < 0.01), pulmonary infection (all P < 0.05), and also had shorter 30-day, 90-day survival and overall survival (OS) (all P < 0.05). Cox proportional hazards regression analysis revealed that recipient MELD score and cold ischemia time were risk factors for the OS in patients with preoperative infection (both P < 0.05). Besides, compared to patients with non-pulmonary infection, those with pulmonary infection were more likely to have effusion and infection (both P < 0.0001), and less likely to have abscess and early allograft dysfunction (both P < 0.05). Patients with non-abdominal infection also had a higher proportion of infection than those with abdominal infection (P < 0.05). Furthermore, compared to patients with single site infection, those with multiple site infection were more prone to effusion and infection (both P < 0.05), and they also had shorter 30-day and 90-day survival (both P < 0.05).

Conclusion: Preoperative infection can result in a higher incidence of early postoperative complications and shorter survival in liver transplant recipients. Different infection sites and the number of infection sites will also influence the prognosis of liver transplant recipients.

Impact of preoperative infection on the outcomes of liver transplant recipients

BMSCs ROS-Responsively Secreting Hepatocyte Growth Factor for Attenuating Hepatic IRI

Shengjun Xu1, 2, Sunbin Ling1, 2, Xiao Xu1, 2

1Zhejiang University School of Medicine Hangzhou China, 2Department of Hepatobiliary and Pancreatic Surgery, Hangzhou First People’s Hospital Hangzhou China

Background: Hepatic ischemia-reperfusion injury (IRI) impairs the clinical efficacy of liver transplantation. After liver reperfusion, reactive oxygen species (ROS) generated from stressed hepatocytes would aggravate liver damage. How to attenuate IRI and improve liver regeneration remains a key problem.

Methods: A ROS-responsive charge-reversal polymer B-PDEAEA has been synthesized and utilized for condensing plasmid DNA to obtain polyplexes. Inspired by the increased ROS during hepatic IRI and the tendency of bone marrow-derived mesenchymal stem cells (BMSCs) to migrate to injured sites, we put forward constructing BMSCs ROS-responsively secreting hepatocyte growth factor (HGF-BMSCs), which could realize efficient and IRI-specific HGF releasing for attenuating IRI.

Results: B-PDEAEA showed limited cytotoxicity to both hepatocytes and stem cells. N/P ratio as 30 was identified as the optimal for gene transfection in MSCs, and the polyplexes exhibited excellent ROS responsiveness and high gene transfection efficiency. HGF-BMSCs have been constructed and could release HGF with the response to ROS. HGF-BMSCs could release over 60000 pg HGF per 10000 cells with low stimulation of H2O2, suggesting the ROS-responsiveness. CM-Dil was used to track stem cells and the biodistribution assay revealed an accumulation of stem cells in injured livers. Furthermore, both in vitro and in vivo experiments showed HGF-BMSCs could protect hepatocytes from IRI, with deceasing of inflammation.

Conclusions: A novel IRI protection system is constructed and promising to be established and to realize targeted and efficient gene/protein therapy, thus providing a theoretical and experimental basis for translational research on the repair and regeneration of transplanted liver.

Novel System for Organ Preservation: Feed Macrophages with Ceria Nanoparticles

Yongquan Chi1, Junda Li1, Guoqiang Shao1, Wenzhu Li1, Zhengfeng Xuan1, Jinhua Song1, Jianhua Rao1

1Hepatobiliary Center of The First Affiliated Hospital, Nanjing Medical University; Research Unit of Liver Transplantation and Transplant Immunology, Chinese Academy of Medical Sciences, Nanjing 210029, China Nanjing China

Background: Liver transplantation, a definitive solution for irreversible liver failure and malignant tumors, has encountered significant challenges predominantly attributable to sterile inflammation following ischemia-reperfusion injury caused by frail donor livers and inadequate preservation techniques. Ceria nanoparticles (CeO2NPs) have antioxidant and anti-inflammatory effects, but their potential use in preserving donor livers remains unknown.

Methods: We created newly designed dextran-coated CeO2NPs that we introduced to solutions used to infuse and preserve murine livers. The biodistribution of CeO2NPs and their association with macrophages were investigated. Additionally, we used a liver transplantation mice model to investigate the roles of CeO2NPs-containing preservation solution on liver injury, reactive oxygen species (ROS), inflammation infiltration and hepatocyte apoptosis. In addition, both in vivo and in vitro studies were carried out to investigate the involvement of CeO2NPs in the potential mechanisms of liver transplantation.

Results: The distribution of CeO2NPs in different organs indicates their specificity in murine liver and Kupffer cells. Additionally, CeO2NPs have been shown to improve liver injury, reduce ROS production and inflammation infiltration, suppress hepatocyte apoptosis in mice that have undergone liver transplantation. Furthermore, the application of CeO2NPs aligns with M2 macrophage polarization, implying that they alleviate sterile inflammation following donor liver implantation through interaction with M2 polarization.

Conclusions: A novel system for infusing and preserving donor livers can be accomplished by deploying CeO2NPs in solution by alleviating sterile inflammation via M2 polarization, which may improve prognosis of patients after liver transplantation in the near future.
Long-term outcomes of fenofibrate for treatment of liver allograft ischemic cholangiopathy

Channa Jayasekera1, Michele Barnhill1, David Chascsa1, Hugo Vargas1
1Mayo Clinic Arizona Phoenix United States

Background: Ischemic cholangiopathy (IC) after liver transplantation has no definitive treatment besides retransplantation. 90-days of fenofibrate—a medication which potently downregulates toxic bile acid production—was recently demonstrated to improve cholestasis by 75% in IC patients during the treatment period. We assessed if these responses were durable beyond 90-days and if fenofibrate was stopped in the previously reported patients.

Methods: Over 360 days, we monitored alkaline phosphatase (ALP) and endoscopic retrograde cholangiography needs of liver transplant recipients who received at least 90 days of fenofibrate.

Results: Of the original 10 patients who received fenofibrate, one patient died of unrelated causes, and one patient had stopped treatment before the 90-day timepoint. Of the remaining 8 patients, 3 patients stopped fenofibrate after 90 days, 3 patients stopped fenofibrate after 180 days, 1 patients stopped fenofibrate at 360 days, and 1 patient did not stop fenofibrate. The initial ALP response seen during the first 90 days of treatment was durable with or without extended fenofibrate treatment. ALP in all patients was 59% of the peak ALP at treatment initiation. No patient required retransplantation.

Conclusion: While IC is a progressive condition of biliary inflammation, fenofibrate therapy initiated early may help arrest its progression with or without long-term treatment.

Utilization of elderly donors in liver transplantation for patients with hepatocellular carcinoma

Liangshuo Hu1, Fan Mu1, Bo Wang1
1First Affiliated Hospital of Xi’an Jiaotong University Xi’an China

Background: Profound organ shortages worldwide have led to the increased utilization of marginal organs from older individuals. However, the effectiveness of liver transplantation (LT) with organs from elderly donors for patients with hepatocellular carcinoma (HCC) remains controversial. The objective of the current study was to assess the overall survival (OS) and disease-free survival (DFS) of patients with HCC following LT using grafts from deceased donors over 60 years old.

Methods: Patients with HCC who underwent LT between 2015 and 2018 were identified in the China Liver Transplant Registry database. The overall survival and disease-free survival of older liver donors (OLDs) were compared with those of younger liver donors (YLDs) after propensity score matching.

Results: From January 2015 to December 2018, a total of 4971 HCC patients were enrolled in the study according to the screening criteria. The absolute and relative utilization of liver grafts from elderly patients over 60 years for HCC patients increased every year, from 65 (9.3%) in 2015 to 268 (14.5%) in 2018. Disease-free survival (DFS) was significantly lower in HCC patients with elderly donors (both P < 0.05) after propensity score matching. The OLD group had worse DFS than YLD group if patients had tumors beyond the Milan criteria (P < 0.05).

Conclusions: The use of older donors for LT has been growing quickly in the last few years in China. Grafts from older donors can be safely used in HCC recipients with similar OS and comparable perioperative complications.

The Therapeutic Potential of Self-Assembled Rapamycin Nanoparticles in Allograft Rejection

Laparoscopic Anatomical Liver Resection with ICG Real-time Shoudai Nagaishi1, Yukari Shinohara1, Yuta Enami1

**Methods:** Soluble supramolecular rapamycin nanoparticles (sRNP) spontaneously form in aqueous solutions via a simple recrystallization scheme, rendering RAPA injectable and providing colloidal stability.

**Results:** Our results demonstrate the sustained maintenance of therapeutic drug concentrations with the sRNP platform, accompanied by commendable pharmacokinetic parameters and minimal toxicity, effectively overcoming the challenge of immunotoxicity. In murine allograft models, the administration of low doses of sRNP over a short duration leads to an increase in myeloid-derived suppressor cells (MDSC) and regulatory T cells (Treg), concurrently reducing Th1 and Th17 cells, surpassing the impact of oral RAPA on graft survival. Evidently, sRNP manages the reduction of effector T cells while amplifying the naive T cell cohort. Transitioning to the rat orthotopic liver transplantation model, a short-term low dose of sRNP (administered once every other day, totaling four times at 0.1mg/kg, intravenously) effectively inhibits T cell proliferation, mitigates inflammatory cell infiltration, significantly prolongs graft survival, and positively influences hepatic function.

**Conclusions:** This study illuminates the distinct advantages of sRNP over its oral RAPA counterpart in the context of allograft rejection, demonstrating the practical feasibility of employing self-assembled RAPA nanoparticles as a potent anti-rejection therapy.

Laparoscopic Anatomical Liver Resection with ICG Real-time Navigation

Tomokazu Kusano1, Takeshi Aoki1, Kazuhiro Matsuda1, Yoshihiko Tashiro1, Tatsuya Yamazaki1, Kazuhiro Saito1, Shoudai Nagashi2, Yukari Shinohara1, Yuta Enami1

1Division of Gastroenterological and General Surgery, Department of Surgery, School of Medicine, Showa University Tokyo Japan

**Background:** In order to perform safe and reliable laparoscopic anatomical liver resection (LALR), it is desirable to establish intraoperative navigation that accurately conducts the proposed surgical plan, in addition to preoperative simulation of local anatomy. In this report, we describe our techniques and innovations using ICG fluorescence imaging and artificial intelligence (AI) for LALR.

**Methods:** Preoperatively, 3D reconstructed images were created from volume data, and simulation of the staining area at ICG injection was performed in all patients. During surgery, three methods of positive staining (PS) were selected according to the case: (1) preoperative puncture with B-mode US before surgery, (2) intraoperative puncture, and (3) combination of the two methods. And, the introduction of a puncture route support system using 3D holography and the development of a new US probe attachment complement the puncture with a red laser. In addition, AI was utilized to assist in the recognition of vascular structures during liver dissection.

**Results:** LALR was performed in 27 positive staining cases and 13 negative staining cases, and ICG staining method enabled accurate navigation in the direction of hepatic resection by distinguishing not only the demarcation lines on the liver surface but also the boundaries in the deep dissection plane. 3D holography and US attachment assisted the optimal puncture route to the portal pedicle branch. The AI recognized the hepatic vein and Glisson branch during dissection of the liver.

**Conclusion:** Real-time navigation using ICG fluorescence and AI can contribute to the realization of safe and precise LALR.

ALPPS vs Conventional Techniques in Hepatitis Related HCC: A Systematic Review and Meta Analysis

Jan Axel Lopez Yusi1,2, Jemimah Andrea Pelayo Fajardo1,3, Sarah Jean Coder Bellido1,2,3, Charles Balita Barretto4,4, Maria Millicent Pingol Cariño4

1St. Luke’s Medical Center Quezon City Quezon City Philippines, 2Institute of Digestive and Liver Diseases, St. Luke’s Medical Center Quezon City Philippines, 3Department of Medicine, St. Luke’s Medical Center Quezon City Philippines, 4Institute of Surgery, St. Luke’s Medical Center Quezon City Philippines

Insufficient functional liver remnant(FLR) volume frequently serves as a major hindrance in performing hepatectomy in cases of primary liver cancers. Current studies show that ALPPS rapidly increase FLR leading to completion of liver resection compared with standard techniques in cases of colorectal liver metastasis. However, there is limited data on its benefit to hepatocellular carcinoma(HCC) associated with chronic hepatitis or cirrhosis. A comprehensive systematic search was performed to include clinical studies that compared ALPPS vs either conventional techniques including TACE+PVE, LAPS, or PVE alone. The Cochrane risk of bias tool and Newcastle Ottawa Scale were used to assess the presence of bias. Data was analyzed using Revman5.4. The primary outcome measured was increase in future liver remnant volume. The secondary outcomes were 1-year and 3-year disease free survival(DFS) and overall survival(OS) rate, perioperative complication rate and liver failure rates.

The study included 4 comparative studies with 284 hepatitis related HCC. There is no statistically significant difference in terms of increase in FLR volume between the two groups [MD -4.84 (95%CI -17.98 - 8.30); p0.47]. The secondary outcomes of 1-year OS(1.19; 0.52-2.71), 3-year OS(2.72; 0.40-18.36), 1-year DFS(0.99; 0.58-1.71), 3-yr DFS(2.14; 0.37- 12.39), overall complication rate(1.15; 0.42-0.52-2.71), 3-year OS(2.14; 0.37- 12.39), overall complication rate(1.15; 0.42-3.14), overall liver failure rate(1.51; 0.33- 6.83), has no statistically significant difference at 95% confidence interval.

Among patients with hepatitis related HCC, ALPPS can be an alternative technique in increasing FLR volume prior hepatectomy. However, there remains a need for larger studies to strengthen this evidence.

Central Hepatectomy with Vascular Reconstruction (Video Abstract)

SAURABH SINGHAL1, Ankur Garg1, Amit Jha1

1Sanar International Hospital Gurugram India

**Aims and Objectives:** Centrally located liver tumors are a surgical challenge that was traditionally treated with extended right or left liver resections leading to a frequent risk of post-hepatectomy liver failure due to inadequate functional liver remnant. Non-anatomic resections are marred by risks of hemorrhage and positive surgical margins.
Central hepatectomy is a feasible choice in such patients with acceptable risks.

**Materials and methods:** In this video, the central hepatectomy steps are shown or a large tumor occupying and right anterior sector and segment 4 followed by vascular reconstruction. The video first discusses adequate mobilization of the liver for exposure. The transaction lines are marked followed by central hepatectomy and reconstruction of the middle hepatic vein using a PTFE graft. Due to the recurrent thrombosis of the right portal vein, it was heparinized through a catheter left in the umbilical vein. Following the completion of the surgery, the patient had an uneventful recovery. The umbilical vein catheter was removed 5 days later.

**Results and Conclusions:** Central hepatectomy is a feasible surgery with acceptable outcomes. In case of the inability to save the middle hepatic vein due to tumor infiltration, an in-situ vascular reconstruction can be done to maintain outflow.

**Risk Factors for Surgical Site Infection after Hepatectomy in Our Facility**

Koichi Nakanishi¹, Hiroji Shinkawa¹, Kosuke Hatta¹, Mizuki Yoshida¹, Takahito Kawaguchi¹, Naoki Tanii², Shuhei Kushiyama², Shigeki Kurihara², Ryota Tanaka², Masahiko Kinoshita³, Kohei Nishino³, Go Ohira¹, Kenjiro Kimura¹, Takeaki Ishiwaza⁴

¹Department of Hepato-Biliary-Pancreatic Surgery, Osaka Metropolitan University Graduate School of medicine Osaka Japan

**Background:** We reported our treatment outcomes for surgical site infection (SSI) following hepatectomy, analyzed and discussed the risk factors.

**Methods:** The study included 1012 cases of hepatectomy without biliary reconstruction or combined resection of other organs from April 2012 to December 2022. Minimally invasive surgery (MIS), including laparoscopic and robot-assisted hepatectomy, was performed in 507 cases (50.1%). As a prophylactic antibiotic, either flomoxef or cefmetazole was administered 30 minutes before and within 24 hours after surgery. A closed abdominal drainage tube was removed 2-4 days postoperatively unless bile leakage was suspected. Perioperative glycemic control was achieved through insulin therapy.

**Results:** Postoperative SSI was observed in 99 cases (9.8%), with 24 cases (2.4%) of incisional SSI and 58 cases (5.7%) of organ/space SSI. Multivariate analysis revealed that poorly controlled diabetes (HbA1c ≥ 6.5%) (odds ratio [OR] 3.31, p=0.0083), major hepatectomy (OR 3.2, p=0.022) and MRSA colonization (OR 4.63, p=0.0083) were significantly associated with incisional SSI. Risk factors for organ/space SSI were age ≥ 65 years (OR 1.96, p=0.029), blood loss ≥ 1500 mL (OR 2.7, p=0.0017), operative time > 300 minutes (OR 3.31, p < 0.001), open surgery (OR 4.28, p=0.0016).

**Conclusion:** Adequate preoperative glycemic control might be effective in reducing the risk of incisional SSI after liver resection. Additionally, for indicated cases, selecting MIS and making efforts to shorten surgery duration and reduce intraoperative blood loss might lead to prevent the development of organ/space SSI.

**Is it possible to minimize liver I/R damage and increase regeneration capacity?**

Sencan Acar¹, Hüseyin Çakıroğlu², Erdem Çokluk³, Özcan Budak⁴, Ahmet Tar Sarı⁴ & Eminler⁵

¹Department of Gastroenterology, Amasya University Serefeddin Sabuncuoglu Research and Training Hospital Amasya Turkey, ²Department of Veterinary Medicine, Sakarya University Faculty of Medicine Experimental Medicine and Research Center (SÜDETAM) Sakarya Türkiye, ³Department of Medical biochemistry, Sakarya University Faculty of Medicine Sakarya Türkiye, ⁴Department of Histology and Embryology, Sakarya University Faculty of Medicine Sakarya Türkiye, ⁵Department of Gastroenterology, Sakarya University Faculty of Medicine Sakarya Türkiye

**Background:** During ischemia and subsequent reperfusion in the liver resulting in apoptosis and necrosis. This study aimed to evaluate the possibility of preventing the reduction of regeneration capacity as a result of ischemia and also to evaluate the possibility of a faster recovery process.

**Methods:** Rats of equal age and approximately equal weight were grouped into 6 groups in total: Group1 = Sham; Group2 = Silymarin-curcumin; Group3 = Silymarin-glucosamine; Group4 = Ganoderma lucidum; Group5 = mixture of group B vitamins, amino acids, l-carnitine and sugar; Group6 = Phenoxy-2-methyl-2-propanionic acid. Liver ischemia was achieved by ligating the hepatic artery under anesthesia for 45 minutes. mTOR, insulin, nesfatin, and leptin levels were checked in the 2nd postoperative week.

**Results:** Insulin levels were found to be low in the silymarin-curcumin group. Regarding blood nesfatin level, it was significantly higher in the 3rd group compared to the control group (p=0.002), and significantly lower in the 2nd group (p=0.015). The blood mTOR level was...
significantly lower in the 3rd group compared to the control group (p=0.051). Other parameters were similar.C3, PCNA, Ki67, mTOR, HGF, and Calpain1.0 were found to be higher in all groups compared to the control group. VGEF and FGF were found to be higher in all groups except group 4 compared to the control group. In immunostaining, more necrosis, vacuolization, and sinusoidal obstruction areas were seen in the 3rd and 4th groups compared to the other groups.

Conclusions: Although all substances applied after I/R injury have been shown to positively affect the regeneration capacity of the liver, silymarin-glucosamine, and ganoderma lucidum have been shown to cause deterioration in the quality of regenerating liver tissue. Apart from this, it was noteworthy that insulin levels were low in the silymarin-curcumin group, which is also used for the treatment of steatotic liver disease.

Outcomes of patients with primary sclerosing cholangitis after liver transplantation

MUHS 聼 N MURAT MUHIP HARPUTLUOGLU1, Mehmet Zeki Calgin2, Sezai Yilmaz3
1INONU UNIVERSITY LIVER TRANSPLANT T INSTITUTE Malatya Turkey, 2Inonu university internal medicine Malatya Turkey

Background and aim: In this study we present the complications and outcomes of PSC patients after liver transplantation in a predominantly LDLT center.

Materials and methods: Adult and pediatric patients who underwent liver transplantation for PSC between February 2008 and October 2020 were included in the study. The demographic characteristics, presence of co-existing diseases, indications for transplantation, type of transplantation, and immunosuppressive treatments used were recorded. Patient survival, survival times, cause of death, recurrences, rejection, and biliary complications were recorded.

Results: Thirty patients who underwent liver transplantation for PSC were included in the study. Twenty-seven patients (90 %) were living donor transplants. The 1-, 3-, and 5-year survival rates after transplantation were 75.9 %, 74.9 %, and 74.9 %, respectively. Biliary complications occurred in 15 patients (50 %). All patients with biliary complications were successfully treated with endoscopic and percutaneous interventional treatments. Chronic rejection occurred in three patients (10 %) and acute rejection occurred in five patients (13.3 %). PSC recurrence developed in five patients (18.5 %).

Conclusion: Biliary complications are the most common complication after liver transplantation in patients with PSC in our center, where LDLT is used extensively and PSC patients are followed closely with respect to biliary complications after transplantation.

Introduction: Finding the best alternative recipient hepatic artery in liver transplantation is hard

Methods: Following PRISMA and NMA guidelines, a comprehensive search of Cochrane Library, MEDLINE, and Scopus was done, analyzing all observational studies that included non-standard anastomosis in liver transplantation, either with the splenic artery, aorta, celiac, or branches from the gastric artery. The outcome parameters are intraoperative, complications, and survival.

Result: Thirteen studies with 9521 subjects were included in this study for quantitative analysis. Aortic anastomosis showed the least complication of thrombosis, stenosis, and biliary tract abnormality. However, inferior results were shown in graft and overall survival. The splenic artery anastomosis alternative showed higher risk of thrombosis, but low complications of stenosis (OR 1.12, 95%CI 0.13-3.14) and biliary tract abnormality (OR 0.79, 95%CI 0.36-1.55). Further, in splenic artery anastomosis, graft survival (OR 1.08; 95%CI 0.96-1.23) and overall survival (1 year survival OR 1.09; 0.94-1.26; 5 year survival OR 1.95%CI 0.83-1.22) showed favorable results. Constraints to the use of the splenic artery were longer operation time and cold ischemic time. However, the duration of hospital stay (MD 1.36, 95%CI -7.47 to 10.8) was shown to be shorter and the need for blood transfusions was minimal (MD -1.74, 95%CI -10.2 to 6.7).

Conclusion: In the case of an unusable recipient’s hepatic artery, the recipient’s splenic artery can be considered as the first choice for anastomosis in liver transplantation.
Clinical characteristics and correlation with liver stiffness post 1 year liver transplantation.

Pranav Vatsayan, Balamurali Rangachari, Manimaran Murugesan, Chitra Shanmugam, Sathya Rajendaran, Krishna kumar Chinadurai

1Department of Medical Gastroenterology and Hepatology, Government Stanley Medical College and Hospital Chennai India

Background: Liver biopsy is a gold standard investigation to assess post transplant fibrosis and steatosis. Its limited by cost and procedural risks. Vibration controlled elastography (VCTE) has shown promise to assess fibrosis and degree of Steatosis in post LT recipients. We present our analysis of VCTE and correlation with clinical characteristics of liver transplant recipients at post 1 year of transplantation.

Method: A total of 38 patients were included in the study who underwent liver transplantation 1 year or prior. VCTE was done for all patients through standard protocol. Pearson bivariate correlation was applied at 95% CI to assess any correlation.

Results: Of total 38 participants, 29 (76%) were male and 9 (14%) were female. Mean duration post transplant was 4.42 years and mean donor age was 28.16 years. Most were deceased liver transplant recipients (n=29). Mean graft weight was 865.62 grams. Mean liver stiffness values obtained were 6.71 kPa (Min: 4.3; Max: 12.8 kPa). We observed that a longer cold ischaemia time was associated with lower liver stiffness (r= -0.216; p=0.193). Higher donor age and graft weight were associated with increased liver stiffness (r=0.256; r=0.143 respectively). More stiffness was observed if patient’s trough tacrolimus levels were high (r=0.181).

Conclusion: Current study was aimed to assess as to what clinical parameters could influence the development of early fibrosis in the recipients. Duration of cold ischaemia time pre-transplant had a strong correlation with degree of stiffness. Higher trough levels of tacrolimus were also associated with higher stiffness. The data presented here is an interim analysis of an ongoing study and further observations will be obtained in future.

A comparative study of laparoscopic liver resection for the segment 4 superior and inferior area

Akira Koizumi, Takeshi Urade, Masahiro Kido, Shohei Komatsu, Hidetoshi Gou, Kenji Fukushima, Shinichi So, Toshihiko Yoshida, Keisuke Arai, Yoshihide Nanno, Daisuke Tsugawa, Sadaki Asari, Hiroaki Yanagimoto, Hirochika Toyama, Takumi Fukumoto

1Department of Surgery, Division of Hepato-Biliary-Pancreatic Surgery, Kobe University Graduate School of Medicine Kobe Japan

Introduction: The difficulty of laparoscopic liver resection (LLR) is greatly associated with the location of liver tumors. According to the IWATE difficulty scoring system, the location in Couinaud’s segment 4 superior area (S4a) scores 4 and inferior area (S4b) scores 3. The difference between LLR for S4a and S4b remains unclear.

Objectives: The aim of this study was to investigate the differences of the surgical outcomes between LLR for S4a and S4b.

Materials and Method: Patients who underwent laparoscopic partial liver resection (LpLR) for the tumors in the S4a and the S4b at Kobe University Hospital between January 2014 and December 2022 were enrolled. We retrospectively investigated perioperative short-term outcomes including the patients’ background, operative results, and complications.

Results: Fourteen patients underwent LpLR for S4. Among these patients, 7 patients underwent LpLR for S4a and 7 patients (50%) for S4b. There was no significant difference between the groups in operation time (274 vs 251 minutes, P=0.7016), blood loss (31.4 vs. 7.9 mL, P=0.0841), the incidence of postoperative complications (0 vs 1 cases, P=1.000), and length of hospital stay (11 vs 12 days, P=0.7382).

Conclusion: There was no difference between LpLR for S4a and S4b in perioperative short-term outcomes. Although the IWATE difficulty score between LpLR for S4a and S4b were different, additional studies with larger number of patients in an independent cohort are necessary.
Effect of Ursodeoxycholic Acid on SARS-CoV-2 Infection in Liver Transplantation Patients

Liangshuo Hu1, Fan Mu1, Bo Wang1

1Sir Run Run Shaw Hospital, School of Medicine, Zhejiang University Hangzhou China

Background: Minimally invasive liver resection (MILR) has become a common surgical treatment for hepatocellular carcinoma (HCC). However, current difficulty scoring system was limited to small samples and single-center, and there was rare scoring system to assess surgery only for HCC. Thus, we developed a novel prediction system based on a multi-enters data to assess the surgical difficulty of MILR for treating HCC.

Methods: The retrospective multicenter cohort study collected a total of 776 cases of MILR for resectable HCC from June 2011 to November 2022 at eight minimally invasive surgical centers in China. The cohort was randomly divided into a training dataset (n = 582) and a dataset (n = 194) in a 3:1 ratio. The training dataset underwent logistic regression analysis to identify independent risk factors for surgical difficulty and construct a prediction model. The performance of the model was validated by the validation dataset, and the discriminative ability, calibration, and clinical effectiveness were assessed through ROC curves and Decision Curve Analysis.

Result: We considered prolonged surgical time, massive intraoperative bleeding, and conversion to open surgery as crucial indicators of a difficult surgery. According to the above criteria, 346 patients underwent a difficult MILR surgery. Gender, Cirrhosis, tumor diameter, and tumor location are independent risk factors affecting the difficulty of MILR for treating HCC. The AUC was 0.785 for the training cohort and 0.723 for the validation cohort.

Conclusions: We developed and validated a novel nomogram to predict the difficulty of MILR for treating HCC based on eastern data.

Effect of Ursodeoxycholic Acid on SARS-CoV-2 Infection in Patients With Liver Transplantation

Liangshuo Hu1, Fan Mu1, Bo Wang1

1First Affiliated Hospital of Xi’an Jiaotong University Xi’an China

Background: Immunosuppressed recipients of liver transplantation (LT) are more likely to develop coronavirus disease 2019 (COVID-19) and may have an increased risk of developing worse outcomes. Aim: To assess the effect of ursodeoxycholic acid (UDCA) on preventing severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) infection in LT recipients.

Design: Adult patients (aged≥18 years) who underwent LT between January 1st, 2015, and December 31st, 2022, were included and categorized into two groups according to their use of UDCA.

Methods: The prevalence and severity of COVID-19 among transplant recipients in the UDCA and non-UDCA groups were estimated and compared.

Results: Among the 897 LT patients who met the inclusion criteria, infection rate of SARS-CoV-2 was 78.4%, and the rate of severe illness was 5.1% from January 2022 to January 2023 in China. In the multivariate analysis, only UDCA treatment (P=0.006) was found to be a protective factor against SARS-CoV-2 infection. After propensity score matching, the SARS-CoV-2 infection rate in the UDCA group was lower than that in the non-UDCA group (74.1% vs. 84.6%, P=0.002). This rate was further reduced to 62.1% (P=0.002) when the oral administration dose was greater than 15 mg/kg/d. There was no difference in the rates of severe COVID-19 illness, ICU admission, or ventilation rate or length of hospital stay with or without UDCA treatment (all P>0.05).

Conclusions: The use of UDCA in LT patients significantly reduced the SARS-CoV-2 infection rate and showed a dose-dependent protective effect.

Laparoscopy specific dorsal approach to the middle hepatic vein in performing left hemihepatectomy

Masaki Ueno1, Shinya Hayami1, Atsushi Miyamoto1, Manabu Kawai1

1Wakayama Medical University Wakayama Japan

Background: Laparoscopic surgery can provide a surgical view that cannot be obtained by open surgery. Herein, we report the surgical procedure of laparoscopic left hemi-hepatectomy by the laparoscopy specific dorsal approach method.

Procedures: (1) Flip-up the left lateral segment and start liver transection from the dorsal surface of the liver around the root of left hepatic vein (LHV). As the root of middle hepatic vein (MHV) also locates near the MHV can be exposed easily and quickly. (2) The left Glissonian branch was encircled and cut. Grasping the stump of the cut Glissonian pedicle and flipping it up, continue liver resection with exposing the MHV toward its periphery direction. (3) After the MHV is exposed entirely and all venous branches to segment IV are cut, then flip-down the left-lateral segment to the original position and transect the liver parenchyma remaining on the ventral side of the MHV from caudal to cranial direction. (4) Finally, cut the LHV by a linear stapler device.

Results: Ten consecutive cases received this procedure. Regarding an anatomical factor, the perpendicular distance from the center of the Arantius plate to the MHV was 1.0 cm on average. The blood loss and operating time were 95 ml and 314 minutes in average. There were no severe postoperative complications.

Conclusions: This procedure enables us to contact the MHV easily and quickly. Moreover, we can avoid split-injury of venous branches during exposure of the MHV. This procedure may be a theoretical method in performing laparoscopic left hemihepatectomy.

Background: Liver resection offers substantial advantages over open liver resection (OLR) for patients with hepatocellular carcinoma (HCC) in terms of reduced blood loss and morbidity. However, there is limited evidence comparing the indications and perioperative outcomes with the open versus laparoscopic approach for resection. This study aimed to compare postoperative outcomes between patients undergoing laparoscopic liver resection (LLR) and OLR for HCC with clinically significant portal hypertension (CSPH).

Methods: A total of 316 HCC patients with CSPH (presence of gastroesophageal varices or platelet count <100,000/ml and spleen diameter >12cm) undergoing minor liver resection at eight centers were included in this study. To adjust for confounding factors between the LLR and OLR groups, an inverse probability weighting method analysis was performed.

Results: Overall, 193 patients underwent LLR and 123 underwent OLR. After weighting, LLR was associated with a lower volume of intraoperative blood loss and the incidence of postoperative complications (including pulmonary complications, incisional surgical site infection, and paralytic ileus) compared to the OLR group. The 3-, 5-, and 7-year postoperative recurrence-free survival rates were 39%, 26%, and 22% in the LLR group and 49%, 18%, and 18% in the OLR group, respectively (p = 0.18). And, the 3-, 5-, and 7-year postoperative overall survival rates were 71%, 56%, and 44% in the LLR group and 76%, 51%, 44% in the OLR group, respectively (p = 0.87).

Conclusions: LLR for HCC patients with CSPH is clinically advantageous by lowering the volume of intraoperative blood loss and incidence of postoperative complications, thereby offering feasible long-term survival.

Optimal radiological assessment for HCC with macrovascular invasion during systemic therapy.

Masanori Inoue1, Sadahisa Ogawara1, Tomomi Okubo2, Norio Itokawa3, Masamichi Obu4, Keisuke Koroki5, Kazufumi Kobayashi6, Naoya Kanogawa7, Ei Itobayashi8, Masanori Atsukawa9, Yoshihiro Koma10, Ryosaku Azemoshi11, Naoya Kato12

1Chiba university hospital Chiba Japan, 2Nippon Medical School Chiba/hokusho Hospital Chiba Japan, 3Nippom Medical School Tokyo Japan, 4Kimitsu Chuo Hospital Chiba Japan, 5Asahi General Hospital Chiba Japan

Background & Aims: Macrovascular invasion (MVI) is a significant prognostic factor in advanced hepatocellular carcinoma (HCC). Existing radiological criteria for evaluating MVI lack clarity in assessing the impact of MVI on systemic therapy. We conducted this study to establish standardized criteria for the assessment of MVI.

Methods: We collected clinical data from advanced HCC patients with MVI undergoing first-line systemic therapy at four medical centers in Japan. We used MVI-PD to monitor MVI progression and cRECIST-PD to assess tumor enlargement and new lesions. We evaluated the prognostic impact of MVI-PD, cRECIST-PD, and MVI control with sorafenib, lenvatinib, atezolizumab, and bevacizumab.

Results: Of the 209 HCC patients with MVI, 20.9% had both MVI-PD and cRECIST-PD. In the landmark analysis, patients without concurrent MVI-PD and cRECIST-PD during the initial 3 months had the longest median OS at 19.7 months, while those with both had the shortest at 5.3 months. The median OS for patients who experienced only cRECIST-PD within the first 3 months was 8.8 months, and median OS for patients who experienced MVI-PD within the first 3 months was 7.2 months (p < 0.001). The correlation coefficient between PFS and OS was similar for MVI-PD (0.451) and cRECIST-PD (0.472). Atezolizumab plus bevacizumab showed longer overall survival than lenvatinib and sorafenib and had a lower incidence of her MVI-PD within 3 months.

Conclusions: Our findings underscore the association between MVI progression and poor OS in systemic therapy for advanced HCC, emphasizing the need for an accurate evaluation method for MVI progression.

irAEs: Immune Mediated Thrombocytopenia

1Department of General and Gastroenterological Surgery, Osaka Medical and Pharmaceutical University Takatsuki Japan, 2Department of Internal Medicine, Teikyo university hospital. Kanagawa JAPAN, 3Department of Gastroenterology, Teikyo university Mizonokuchi hospital. Kanagawa JAPAN, 4Department of Internal Medicine, Teikyo university Mizonokuchi hospital Kanagawa JAPAN

Purpose: To investigate the selection and outcome of “post-treatment” of ATZ+BEV in real-world clinical practice.

Methods: A retrospective multicenter study was conducted on 53 patients with advanced hepatocellular carcinoma treated with ATZ + BEV from September 2020 to December 2022. The final follow-up date was March 15, 2023. The primary endpoint was the rate of sequence active treatment after PD. Secondary endpoints were PS at the end of ATZ+BEV, liver function, proteinuria, posttreatment therapy, OS after starting posttreatment, OS after starting ATZ+BEV, and OS from the initial diagnosis day of HCC.

Results: The median age was 74 years. 13 patients were Stage III, 12 patients IV-A, 26 patients IV-B, 46 patients Child-Pugh A, and 7 patients B. After ATZ+BEV treatment, 40/53 patients (75%) completed. PS2 or higher at the end of ATZ+BEV was 7/40, Child-Pugh A 27/B 11, proteinuria 3+ 7/40. Post-treatment therapy included lenvatinib in 10 patients, ramucirumab in 2, cabozantinib in 4, TACE in 7, sorafenib in 2, and BSC in 16. The rate of sequence active treatment was 59%. MST after initiation of active post-treatment was 9.2 months, MST after initiation of ATZ+BEV was 16.8 months, and MST from the first treatment was 7.0 years.

Conclusion: After completion of ATZ+BEV, sequence active treatment was possible for patients with preserved residual liver function and PS. The rate of sequence active treatment was 59%, and the MST was 9.2 months. It was suggested that sequence active treatment may contribute to further prolongation of survival.
**Introduction:** Durvalumab is an anti-PDL1 immune checkpoint inhibitor that has become one of the first line systemic treatment in patients with Hepatocellular Carcinoma. Its incidence is estimated to be as low as 0.5% with an absolute frequency that is still unknown. Physicians should be alert of the rare adverse effects such as severe thrombocytopenia. The most important questions that should be answered when dealing with irAE are how frequently to monitor, when to withhold or discontinue ICIs, when to initiate and how to escalate immunosuppression.

**Clinical Presentation:** This is a case of a 60-year-old male, known case of compensated liver cirrhosis secondary to non-alcoholic steatohepatitis and chronic hepatitis B infection complicated by Hepatocellular carcinoma BCLC C. Twenty four hours after initiation of Durvalumab, the patient presented with acute severe thrombocytopenia (32,000/mm²) from a normal baseline platelet count (162,000/mm²), accompanied by episodes of hemorrhoidal bleed.

An exhaustive work-up for possible causes of thrombocytopenia began which all revealed negative results for infectious, rheumatologic and hematologic causes.

**Management:** Given the temporal profile of thrombocytopenia occurring after Durvalumab infusion and the exclusion of other possible factors, patient was managed as a case of Grade 3 irAE, namely Immune Mediated Thrombocytopenia. Initially, the patient was started on steroids, however there was persistence of thrombocytopenia. He was eventually given IVIG and Eltrombopag which led to the gradual increase of his platelet count.

**Conclusion:** Immune checkpoint inhibitors have reshaped cancer therapy. Early and aggressive medical interventions are necessary to successfully achieve irAE improvement after initiation of ICIs.

---

**Comparative Efficacy of Regorafenib, Cabozantinib, and Ramucirumab for unresectable HCC.**

Kaori Mukai1, Tasuku Nakabori1, Masaki Kawabata1, Kana Hosokawa1, Hiroki Kishimoto1, Yusuke Seiki1, Ko Watsuji1, Kazuhiro Kozumi1, Makiko Urabe1, Yugo Kato1, Ryoji Takada1, Kenji Ikezawa1, Hiroyuki Uehara1, Kazuyoshi Ohkawa1

1Osaka International Cancer Institute Osaka Japan

**Background:** A comparison of the therapeutic efficacy of regorafenib, cabozantinib, and ramucirumab in late-stage treatment for unresectable hepatocellular carcinoma (u-HCC) has not been reported. This study aimed to retrospectively compare the outcomes of u-HCC and identify which of these should be used as prior therapy.

**Methods:** Twenty-seven patients with u-HCC treated with regorafenib, cabozantinib, and ramucirumab from July 2017 to January 2023 were analyzed; patients who received more than one of the three drugs were included in the prior drug group. All patients had received lenvatinib, atezolizumab/bevacizumab, or both as previous therapies. Disease control rate (DCR), progression-free survival (PFS), and overall survival (OS) were evaluated according to modified Response Evaluation Criteria in Solid Tumors (mRECIST).

**Results:** There were no significant differences among these three groups in DCR (regorafenib vs. cabozantinib vs. ramucirumab: 70% vs. 25% vs. 46%; p=0.26) and median PFS (3.4 months vs. 2.6 months vs. 2.0 months; p = 0.54). Median OS was statistically shorter in the ramucirumab group than in the other two groups (regorafenib vs. cabozantinib vs. ramucirumab: 28 months vs. 13.6 months vs 5.4 months; p = 0.030). Although there were cases of long-term response in the regorafenib group, there was no statistically significant difference in OS between the regorafenib and cabozenitib groups. There were no grade 3 or higher adverse events in the ramucirumab group. Discontinuation rates due to adverse events were not significantly different between these three groups (p=0.14).

**Conclusions:** Cabozantinib or regorafenib may contribute to OS when compared to ramucirumab.
Background: Atezolizumab plus bevacizumab (Atezo/Bev) followed by curative conversion therapy (ABC-C) outcomes for unresectable hepatocellular carcinoma (u-HCC) that achieved tumor shrinkage with Atezo/Bev therapy has attracted attention. We conducted a multicenter study of Atezo/Bev therapy and examined the outcomes of ABC-C.

Methods: We enrolled a multicenter cohort of 205 patients with u-HCC treated with Atezo/Bev therapy between 2020 and 2022. The decision to perform curative conversion therapy was based on each facility’s discretion. Propensity score matching (1:3 ratio) was used to create two matched patient groups: the ABC-C group or the group that did not receive curative conversion therapy (Atezo/Bev group). We retrospectively compared the clinical outcomes, including overall survival (OS), progression-free survival (PFS), clinical cancer-free, and drug-free rates, between the two groups.

Results: The median follow-up time for all patients was 14 months. The modalities of curative conversion in 13 patients were as follows: resection, 4; ablation, 3; and super-selective TACE, 6. The clinical conversion rates, between the two groups.

Conclusion: ABC-C therapy may provide more clinical benefits than Atezo/Bev without conversion in u-HCC patients.

Metalloimmunology-based nanoclusters activate the immune to enhance pembrolizumab plus lenvatinib

Yongwei Hu

1Department of Hepatic Surgery and Liver Transplantation Center, The Third Affiliated Hospital, Sun Yat-sen University, Guangzhou, 510630, China Guangzhou China

Background: Targeted therapy combined with immunotherapy has become the first-line option for advanced unresectable Hepatocellular carcinoma (HCC). The combination of pembrolizumab plus lenvatinib did not meet the dual endpoints of PFS and OS in LEAP-002. In recent years, the role of metals in the immune microenvironment has attracted attention, and the aim of this study was to explore the efficacy and mechanism of the metalloimmunology-enhancing pembrolizumab plus lenvatinib in advanced HCC.

Methods and Results: We found lenvatinib possesses an eFT-508-like effect to downregulate PD-L1 expression in HCC cells by computer simulation (CADD). Dual luciferase reporter gene assays demonstrated that lenvatinib could downregulate PD-L1 expression by modulating the uORF of PD-L1, and that cobalt ions could enhance this effect. Lenvatinib combined with cobalt ions had a synergistic inhibitory effect on the growth of HCC cells, and the synergy index (CI) indicated the strong synergistic effect. We constructed Co+Len@OVA drug-carrying nanoclusters, which could effectively inhibit the growth and invasion of HCC cells and could trigger the immunogenic death (ICD) by blocking autophagic flux and activating the cGAS-STING pathway. As a result, Co+Len@OVA promotes the antigen presentation function of DC cells as well as the activation of adaptive immunity dominated by CD8+ T cells. In vivo experiments, Co+Len@OVA transformed HCC from “cold tumors” into “hot tumors”. In addition, Co+Len@OVA combined with anti-PD1, as a novel combination of pembrolizumab plus lenvatinib, can induce tumor vascular normalization and increase anti-PD1 intra-tumor penetration.

Comparison of therapeutic effects of lenvatinib and HAIC for unresectable HCC with vascular invasion

Shuya Maeshima1, Yoshiyuki Ida1, Ryo Shimizu1, Shiori Kaji1, Yudai Taniguchi1, Reiko Ashida1, Takao Maekita1, Mikitaka Iguchi1, Masayuki Kitano1

1Wakayama medical university Wakayama city Japan

We compared the therapeutic effects of lenvatinib (LEN) and hepatic arterial infusion chemotherapy (HAIC) as primary treatment for unresectable HCC with vascular invasion. 33 unresectable HCC with vascular invasion patients participated in this study who were treated by LEN or HAIC as primary treatment at our hospital between April 2016 and March 2022. 16 patients were LEN group, 17 were HAIC group. Median age 69 years, 2/10/11 cases with Vp0/2/3, 28/2/3 cases with Vv0/2/3. We compared background factors, overall survival (OS), progression free survival (PFS), objective response rate (ORR), and disease control rate (DCR) between the two groups. We analyzed factors affecting OS and PFS. Age and DCP value were significantly higher in LEN group. Median OS was 9.8 months in LEN group and 6.2 months in HAIC group (p=0.040). Median PFS was 4.7 months in LEN group and 2.3 months in HAIC group (P=0.124). ORR and DCR by mRECIST were 43.8% and 68.8% in LEN group and 29.4% and 64.7% in HAIC group, with no significant difference. In the univariate analysis of poor OS factors, ALBI grade 2b or 3 was a significant factor in HAIC group. In univariate analysis of poor PFS factors, distant metastasis and AFP 400ng/mL or more were significant factors in HAIC group. Multivariate analysis revealed no significant factor. Compared with HAIC, LEN administration is less affected by background factors such as ALBI grade, distant metastasis, and AFP value. We think that LEN is more suitable as primary treatment for unresectable HCC with vascular invasion.

Abstract Submission No. 102063

Efficacy of TACE guidance software for hepatocellular carcinoma in the caudate lobe

Shiro Miyayama1, Masashi Yamashiro1, Rie Ikeda1, Akira Yokka1, Takeo Fujita1, Naoko Sakuragawa1

1Fukui-ken Saiseikai Hospital Fukui Japan

Background: To evaluate the outcomes of conventional transarterial chemoembolization (TACE) using guidance software for hepatocellular carcinoma (HCC) in the caudate lobe. Methods: Seventy-six treatment-naive caudate lobe HCCs were eligible. TACE was performed using guidance software including automated tumor-feeder detection (AFD) functionality. Technical success was classified into three grades according to 1-week computed tomography findings: entire tumor embolized with a safety margin (5 mm for tumors ≤25 mm and 10 mm for tumors ≥25 mm) (grade A); entire tumor embolized without a margin (grade B); and entire tumor not embolized (grade C). Tumor response was evaluated using the modified Response Evaluation Criteria in Solid Tumors. Tumor-feeder detectability by AFD, technical success, complete response (CR) at 2-4 months, and local tumor progression (LTP) rates calculated by the Kaplan-Meier method were compared in each tumor among three
subsegments: the Spiegel lobe (SP); paracaval portion (PC); and caudate process (CP).

Results: The mean tumor diameter was 18.6 ± 9.7 mm (range, 6-53 mm), and 107 (88.4%) of 121 tumor-feeders were detected by AFD. The rates of feeder detectability by AFD, grade A technical success, and CR in 32 SP, 33 PC, and 11 CP tumors were 73.7%, 96.9%, and 93.8%; 97.0%, 63.6%, and 60.6%; and 87.5%, 63.6%, and 81.8%, respectively. LTP rates of SP tumors were significantly lower than those of PC tumors (P = 0.0019).

Conclusion: AFD could detect 88.4% of tumor-feeders in the caudate lobe; however, the feeder detectability, technical success, and outcomes differed among the three subsegments.

TACE combined with donafenib plus PD-1 for unresectable HCC: a retrospective study

Yahua Li¹, kewei Ren¹, Xinwei Han¹
¹The First Affiliated Hospital of Zhengzhou University Zhengzhou China

Background: To retrospectively evaluate the effectiveness and safety of transarterial chemoembolization (TACE) combined with donafenib plus programmed cell death protein 1 (PD-1) for unresectable hepatocellular carcinoma (uHCC).

Methods: Patients with uHCC who received TACE combined with donafenib plus PD-1 from 1 Feb 2022 to Aug 2022 were included in this study. The primary endpoint was overall survival (OS), progression-free survival (PFS). The secondary endpoint was objective response rate (ORR) and disease control rate (DCR). The tumor response was evaluated according to the mRECIST standard. Safety was assessed by the occurrences of adverse events and the severity of the adverse events.

Results: A total of 144 patients were involved in this study. All patients were treated with TACE combined with donafenib and PD-1. Up to the time of follow-up, 24 patients died, 13 patients were lost, and 107 patients survived. The median OS of TACE combined with donafenib and PD-1 was 13 months, and the median PFS was 6 months. The ORR was 73.61% and DCR was 91.67%. No treatment-related death occurred in the follow-up time. Five patients experienced Grade 3 or 4 AEs with diarrhea, rash or vomiting. Drug reduction occurred in the follow-up time. Five patients experienced Grade 3 or 4 AEs. Drug reduction occurred in the follow-up time. Fifty-nine patients achieved CR, and PD was 2.6 months, respectively.

Conclusion: AFD could detect 88.4% of tumor-feeders in the caudate lobe; however, the feeder detectability, technical success, and outcomes differed among the three subsegments.

AFP Response Patterns after Radioembolization of Hepatocellular Carcinoma Predicts Disease Outcomes

Jessica T. Wen¹, Luyao Shen¹, Justin R. Tse¹
¹Stanford University School of Medicine Palo Alto United States

Purpose: To describe alpha-fetoprotein (AFP) response patterns and outcomes in patients with AFP-producing Barcelona Clinic Liver Cancer (BCLC) stage B or C hepatocellular carcinoma (HCC) after Y-90 radioembolization.

Methods: This IRB-approved, single-center, retrospective study included 167 adults from 2009-2022 with AFP-producing HCCs (≥20 ng/mL) without extrahepatic metastases who underwent Y-90 radioembolization. The AFP treatment response was categorized into 3 patterns: 1) sustained response (sustained post-procedure AFP decrease by ≥20%; n=42), 2) transient response (decrease by ≥20%, followed by an increase thereafter; n=67), and 3) no response (<20% decrease or increased AFP; n=58). Two fellowship-trained abdominal radiologists evaluated pre-treatment and post-treatment imaging for baseline stage and treatment response using mRECIST, respectively. Overall survival (OS), distant progression-free survival (DPFS), and progression-free survival (PFS) were estimated with Kaplan-Meier curves.

Results: 167 patients were included (37 women, 130 men; 80 Stage B and 87 Stage C; median age 65 years). Median OS of sustained, transient, and no response were 18, 13, and 6.4 months, respectively (p<0.0001). Median DPFS of sustained, transient, and no response were 14, 7, and 3.4 months, respectively (p<0.0001). Median PFS of sustained, transient, and no response were 11, 3.7, and 2.6 months, respectively (p<0.0001). The sites of extrahepatic metastases at first imaging examination showing progression were lungs (40%), lymph nodes (30%), bones (21%), peritoneum (17%), and adrenal glands (14%).

Conclusions: AFP response patterns correlate with clinical outcomes. Only about 1/4 of patients have sustained AFP response. Increased AFP after treatment should prompt imaging with attention to lungs, lymph nodes, and bones.

Abstract Submission No. 100785

Early Response to HAIC Using Lipiodol, Cisplatin, and 5-FU for Locally Advanced HCC in Vietnam

DUY ANH NGUYEN³, LE LAM NGO³
³Viet Nam National Cancer Hospital Hà Nội Vietnam

Background: This study aimed to evaluate the early response (ER) to hepatic arterial infusion chemotherapy (HAIC) utilizing Lipiodol, Cisplatin, and 5-FU in patients who had locally advanced hepatocellular carcinoma (HCC) with portal vein invasion (PVI).

Methods: We conducted a prospective study involving twelve patients, each receiving an implanted subcutaneous port for HAIC. The treatment regimen consisted of Lipiodol, Cisplatin, and 5-FU. Each treatment course spanned four weeks and included five days of chemotherapy per week during the first, second, and fourth weeks. One week after the first course, the patients were examined and categorized into complete response (CR), partial response (PR), stable disease (SD), and progressive disease (PD) using mRECIST criteria.

Results: Of the patients, 9 (75%) demonstrated early response (ER) to treatment, with one (8.3%) achieving CR and eight (66.7%) exhibiting PR. One patient (8.3%) experienced PD, while two (16.7%) had SD. Additionally, portal vein tumor thrombosis showed shrinkage in 3 patients (25%), and liver function improved in 2 patients. Complications occurred in four patients (33.3%), including infection, hematemesis, thrombosed catheter, and catheter breakage.

Conclusions: The HAIC regimen consisting of Lipiodol, Cisplatin, and 5-FU demonstrated a notable rate of ER, substantial reduction in portal vein tumor thrombosis, and improved liver function. While complications were relatively common, they did not pose life-threatening risks.

AFP Response Patterns after Radioembolization of Hepatocellular Carcinoma Predicts Disease Outcomes
Radioembolization with 90Y Resin Microspheres and Voxel-Based Dosimetry with Integrated 90Y PET/MRI

Burak Demir, Cigdem Soydal, Nuriye O. Kucuk, Emre C. Celebioglu, Mehmet S. Bilgie, Didgdem Kuru Oz, Atilla H. Elhan, Kemal M. Kir

1Ankara University Medical School Department of Nuclear Medicine, Ankara Turkey, 2Ankara University Medical School Department of Radiology Ankara Turkey, 3Ankara University Medical School Department of Biostatistics Ankara Turkey

Background: Radioembolization is a regional treatment modality that can be applied varied primary and metastatic liver tumours. In this study we aimed to determine dosimetric parameters that could be useful in prediction of response to therapy.

Methods: In this study 34 patients treated with Y-90 resin microspheres prospectively included in the study. The patients were imaged with integrated PET/MRI system in 24 hours following radioembolization procedure. Total number of 70 lesions that could be delineated on pre-treatment FDG or DOTATATE PET were included in dosimetric analysis. Each lesion was classified as complete (CR), partial (PR), stable (SD), and progressive (PD) depending on follow-up PET findings.

Results: Of the treatments, 9 were hepatocellular carcinoma, 15 were colorectal carcinoma and the remainder were breast, thyroid, neuroendocrine and cholangiocellular carcinoma. Median Davg values for responder lesions (CR+PR) were 114.90 Gy and for non-responder lesions (SD+PD) were 36.30 Gy. Addition to average dose (Davg), D values from dose-volume histograms were significantly different within response groups. In ROC analysis to predict response (CR+PR) AUC for Davg, D70, D80, D90 were 0.850, 0.884, 0.889, 0.854 respectively. Furthermore, to predict CR AUC were 0.759, 0.792, 0.814 and 0.812, for Davg, D70, D80 and D90 respectively. High specificity cut-off for Davg, D70, D80, D90 were 0.850, 0.884, 0.889, 0.854 respectively.

Conclusion: Dosimetric analysis of Y-90 PET/MRI can predict response and complete response after radioembolization treatment and may help clinicians to take measures early on after the treatment.

Hepatic Artery Embolization Promotes T-cell Exhaustion in Rat Hepatocellular Carcinoma Model.

Haruyuki Takaki, Naoki Kodama, Reona Wada, Hiroshi Kodama, Koichihiro Yamakado

1Hyogo Medical University Hyogo Japan

Purpose: T-cell exhaustion is a state of T-cell dysfunction that occurs in chronic infections and cancer. This study was undertaken to evaluate the effects of hepatic artery embolization (HAE) on tumor-infiltrating lymphocytes (TIL) of an orthotopic rat hepatocellular carcinoma (HCC) model by focusing on T-cell exhaustion.

Materials and methods: A rat HCC model was established in Sprague-Dawley rats with the NIS1 cell line. Five animals each were assigned to receive HAE or sham treatment. HCC nodules were collected and digested to generate single-cell suspensions for immunological characterization at 5 days after treatment. The population of PD-1 "LAG-3" exhausted cells among the CD8 TILs was evaluated by flow cytometry. In vitro cell culture study of splenic mononuclear cells was performed for 5 days under normoxic or hypoxic conditions in the presence or absence of glucose with or without tumor lysate, and the population of exhausted cells was evaluated by flow cytometry.

Results: The population of PD-1 "LAG-3" cells among the CD8 TILs was significantly larger in the HAE group as compared with the sham group (p<0.05). In vitro cell culture study revealed that the populations of exhausted CD8 cells significantly increased when cells were cultured without glucose with tumor lysate in both normoxic (p<0.05) and hypoxic (p<0.05) conditions.

Conclusions: HAE promotes T-cell exhaustion in the tumor immune microenvironment of a rat HCC model. Metabolic stress with continuous antigen stimulation is a possible mechanism underlying T-cell exhaustion after HAE.

Efficacy of HAIC New-FP for Unresectable Advanced Intrahepatic Cholangiocarcinoma

Hiroto Ota, Hiroaki Nagamatsu, Takuya Watanabe, Ippei Ikoma, Yasuhiisa Jinho, Daishi Kabemura, Muneo Ikemura, Ayaka Mathida, Akinori Suzuki, Yusuke Takasaki, Daisuke Namima, Shigeto Ishii, Yoshio Fujisawa, Hiroyuki Isayama

1Juntendo university Tokyo Japan

Background: Treatment with chemotherapeutic agents for unresectable Intrahepatic Cholangiocarcinoma (ICC) is still unestablished. We evaluated the efficacy of Hepatic Arterial Infusion Chemotherapy New-FP (NFP) compared with gemcitabine+cisplatine(GC) therapy for unresectable ICC.

METHODS: Patients with unresectable ICC who underwent chemotherapy between March 2015 and March 2023 in Juntendo university hospital were retrospectively evaluated. We evaluated the efficacy and safety of NFP, and anti-tumor effect was evaluated by RECIST and tumor volume reduction rate with contrast-enhanced CT.

Results: Totally 30 cases, each 15 in NFP and GC group were enrolled. Antitumor effects by RECIST in the NFP/GC group was 5 /1 PR (33.3%), 8/8 SD, and 2/6 PD, and the DCR was 86.7%/60 %. PR rate was higher (33.3% vs 6.6%) (p=0.0374) in the NFP group. Median tumor volume reduction more than SD cases (NFP/GC) was 23.8%/11.3%, time to best response was 155/87days, and median observation period was 248/464days. About Chemotherapy side effect in the NFP group, Grade ≥ 3 hepatic dysfunction was observed in all patients, but all of them improved within 1 week, Grade3 thrombocytopenia occurred in11, Grade3 anemia in 1, Grade 2/3 renal impairment in 1/3, biloma in 1. In the GC group, Grade 4 neutropenia occurred in 1, Grade 2 renal impairment in 8, Grade 5 anorexia in 1, and vasculitis in 1.

Conclusion: To confirm the efficacy, we should accumulate more cases and perform prospective study.

Hepatic arterial infusion chemotherapy Survives as a Last Resort

Shuntaro Obi, Shinpei Sato, Takahisa Sato, Miho Kanda, Yuji Kondo, Toshihiro Kawai, Takamasa Ohki, Mayuko Kondo, Kininori Sato, Hideo Yoshida, Hiroyuki Taniguchi, Yasushi Uchino, Masatoshi Akamatsu, Yukihiro Koike, Eriko Goto
Gastroenterology and Hepatology, Kyoudo Hospital of Sasaki Institute Tokyo JAPAN, 1Department of Gastroenterology, Mitsui Memorial Hospital Tokyo JAPAN, 2Department of Gastroenterology, Japan Red Cross Medical Center Tokyo JAPAN, 3Department of Gastroenterology, JR Tokyo General Hospital Tokyo JAPAN, 4Department of Gastroenterology and Hepatology, Kyoudo Hospital of Sasaki Institute Tokyo JAPAN, 5Department of Gastroenterology, JR Tokyo General Hospital Tokyo JAPAN, 6Department of Gastroenterology, Kanto Central Hospital Tokyo JAPAN

Objective: Review the outcomes of hepatic arterial infusion chemotherapy (HAIC) and systemic chemotherapy in our experience.

Methods: 875 cases of HAIC, 171 cases of Sorafenib, 226 cases of Lenvatinib and 85 cases of Atezolizumab + Bevacizumab were included in the analysis. Overall Survival of all cases and OS by Vp status were calculated.

Results: Median Survival Time (MST) for all patients of HAIC was 6.8 months. MST by Vp limited to Child-Pugh A for comparison with other drugs was 7.6 months with Vp and 10.8 months without Vp. The MST for the Sorafenib patients was 10.2 months, and the MST by Vp was 7.1 months with Vp and 14.3 months without Vp. The MST for lenvatinib patients was 16.2 months, and the MST by Vp was 7.0 months with Vp and 17.6 months without Vp. The MST for the ATZ + BEV patients was 18.7 months, and the MST by Vp was 16.1 months with Vp and 19.7 months without Vp.

Conclusion: The standard of care is ATZ + BEV, even in the presence of portal vein tumor invasion. However, for Child-Pugh B patients and those who do not respond to systemic chemotherapy, HAIC will survive as a "last-resort" therapy.

Secretome methods show an active arachidonic acid metabolism indicates TACE response in HCC patients

Zijian Zhang1, Qi Zhou1, 2

1Department of General Surgery, Hui Ya Hospital of The First Affiliated Hospital, Sun Yat-sen University Huizhou China, 2Department of Hepatic Surgery, The First Affiliated Hospital, Sun Yat-sen University Guangzhou China

Background: Arachidonic acid is a polyunsaturated omega-6 fatty acid that plays a crucial role in the inflammatory response within the body. It is found in the phospholipids of cell membranes and is released by the action of phospholipase A2 enzymes when cells are damaged or under stress. Most of the studies of TACE are post-operational and retrospective. Here, we adopted a prospective study RNA-Seq data to explore the relationship between Secretome and TACE responses of HCC patients. Understanding and manipulating this relationship can have therapeutic implications for improving the efficacy of TACE and potentially other cancer treatments.

Methods: Secretome data was obtained from The Human Protein Atlas database. The RNA-Seq data was utilized from the Gene Expression Omnibus (Accession: GSE104580) which shows the secretomes profile of TACE in HCC patients. R language and packages are used to explore data signatures and statistics.

Results: After the analysis of RNA-Seq data with prospective results of TACE of HCC patients, we found the differential expression of secreted proteins between response and non-response formed an obvious enrichment in the Arachidonic Acid Metabolic Process (GO:0019369).

Conclusion: The enrichment of secreted proteins in the Arachidonic Acid Metabolic Process shows a potential pathway to predict the efficiency of TACE in HCC patients before the operation. And the secreted proteins are easier to be detected in blood. The Arachidonic Acid Metabolic Process proteins and metabolites are also promising means of prediction and therapeutic targets for HCC patients.

Transcatheter Arterial Embolization of hepatic hemangiomas: Efficacy and Predictors of Response

Dan Zhao1, Lingli Xie2, Lian Yang1, Chuansheng Zheng1, Liangrong Shi3, Bin Liang4

1Department of Radiology, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology Wuhan China, 2Department of Gastroenterology, General Hospital of the Yangtze River Shipping Wuhan China, 3Department of Radiology, Xiangya Hospital, Central South University Changsha China

Background: Hepatic hemangioma (HH) is increasingly treated with Transcatheter arterial embolization (TAE). Given the lack of detailed information on the factors influencing TAE’s efficacy and the tumor’s response to treatment, this study aims to evaluate the safety, efficacy and predictors of response of TAE to treat HH.

Methods: A retrospective analysis was conducted of consecutive HH patients who received TAE with bleomycin-Lipiodol emulsion and gelatin sponge particles at three institutions from January 2014 to January 2021. TAE effectiveness was defined as more than 50% reduction of tumor volume. The effectiveness, safety, and CT changes of hemangiomas after TAE were assessed. Factors affecting TAE efficacy on tumor size were analyzed with logistic regression analysis.

Results: A total of 102 patients with 109 HHs were included. After treatment, both the tumor diameter and volume were significantly reduced from 8.5 ± 3.9 cm to 5.9 ± 3.8 cm (P < 0.001) and 412.6 ± 742.3 cm³ to 102.0 ± 232.7 cm³ (P < 0.001), respectively. TAE effectiveness was achieved in 80.7% (88/109) of hemangiomas, which was characterized by progressive reduction in tumor volume over time. Atypical enhancement pattern (p = 0.001) and central arterioportal shunt (APS) (p = 0.002) associated with the tumor were independent predictors of TAE ineffectiveness. Postembolization syndrome and transient increase in liver enzymes were common without severe complications and death.

Conclusion: TAE was safe and effective in reducing HH size, with characteristic changes during follow-up CT. Lesion enhancement pattern and APS type were associated with TAE efficacy on HH size.

In-stent Restenosis After Stenting for Superior Mesenteric Artery Dissection

Zhongzhi Jia1

1The Affiliated Changzhou Second People’s Hospital of Nanjing Medical University changzhou China

Objective: To identify risk factors for in-stent restenosis (ISR) in patients undergoing stent placement for superior mesenteric artery dissection (SMAD) and to determine the hemodynamic mechanism underlying ISR.

Methods: Patients with SMAD who had ISR after stent placement were included in the ISR group, and age- and sex-matched patients with SMAD who did not experience ISR after stent placement were included in the control group. Structural and fluid dynamics
The relationship between pancreatic hormone and liver in acute hepatic failure.

A Change in Strategy for Filter Choice Leads to Improved Filter Retrieval Rates
Zhongzhi Jia1
1The Affiliated Changzhou Second People’s Hospital of Nanjing Medical University changzhou China
Objective: To assess whether a new strategy for the choice of inferior vena cava filter placed would improve filter retrieval rates at our institution.
Methods: Consecutive patients who underwent retrievable filter placement for temporary embolic protection between January 2021 and January 2022 were considered for study inclusion. Risk factors for nonretrieval of short-term filters were identified in patients receiving filters between January 2021 and January 2022 (prestrategy group). For patients treated between February 2022 and January 2023 (poststrategy group), a long-term filter was recommended for those with these risk factors, and a short-term filter was recommended for those without these risk factors.
Results: The study population included 303 patients (prestrategy group, n = 154; poststrategy group, n = 149). Long-term immobilization (odds ratio [OR] = 38.000; 95% confidence interval [CI]: 6.858-210.564), active cancer (OR = 17.643; 95% CI: 5.462-56.993), and venous thromboembolism detected in the intensive care unit (OR = 28.500; 95% CI: 7.419-109.477) were identified as independent risk factors for nonretrieval of short-term filters. The total retrieval rate was significantly higher in the poststrategy group (87.2%) than in the prestrategy group (72.7%; P = 0.002); the short-term filter retrieval rate was also significantly higher in the poststrategy group (84.5%) than in the prestrategy group (68.5%; P < 0.001).
Conclusion: The proposed strategy for filter choice based on risk factors for short-term filter nonretrieval can accurately identify patients who need long-term filter placement while also increasing the retrieval rates for both short-term filters retrieval rates and overall retrieval rates.

Naoki Hashimoto1
1Sanda city hospital Snda city Japan
A canine model of an acute hepatic failure was created by the administration of Dimethylnitrosamine (DMN) (30mg/kg) via portal vein. Using this model, the hepato-pancreatic relationship was studied by measuring the pancreatic endocrine function of portal blood and hepatic blood flow. As a result, while the plasma level of IRI of portal blood was higher than basal level of IRI when the hepatic damage was mild, the former was similar to control when the hepatic damage was severe. On the other hand, the more severe the hepatic damage was, the higher the plasma level of IRG of portal blood was. Hypoglycemia and a considerable high level of portal IRG were shown in an acute hepatic failure. These results strongly suggest that pancreatic endocrine function of portal blood may reflect the grade of hepatic damage and a hormonal or neural hepato-pancreatic relationship may exist between the liver and the pancreas.

Abstract Submission No. 100242

Thymosin α1 improves immune imbalance in hepatitis B virus-related acute-on-chronic liver failure
Zhihui Li1, Jing Zhang1, Bingliang Lin1
1The Third Affiliated Hospital of Sun Yat-sen University Guangzhou China
Background and aim: Thymosin α1 (Tα1) is safe for patients with hepatitis B virus (HBV)-related acute-on-chronic liver failure (ACLF) and significantly improves the 90-day survival rate without liver transplantation; however, the immune mechanism remains unclear.
Methods: This study was an open-label, randomized, controlled clinical trial including 73 patients with HBV-related ACLF (HBV-ACLF) (Clinical Trial ID: NCT 03082885). The control group (SMT group, N=38) received standard medical therapy, while the experimental group (Tα1 group, N=35) received Tα1 combined with SMT by subcutaneous injection. Blood samples and clinical data were collected for analysis.
Results: We found that patients with ACLF had a higher proportion of regulatory T cells (Tregs) than the healthy people, suggesting that differentiation of T cells into effector T cells was limited in patients with ACLF. At baseline, patients who had survived at 90 days had a higher proportion of effector T cells and a lower proportion of Tregs than did patients who were deceased. Analysis of the serum cytokine profiles of surviving patients also showed higher levels of the serum interleukin (IL)-6, tumor necrosis factor (TNF)-α, and interferon (IFN)-γ and lower levels of the serum transforming growth factor (TGF)-β, compared with those in the deceased patients. More importantly, we found that Tα1 treatment can inhibit worsening of the inflammatory storm and restore the immuno-inflammation balance, thus improving prognosis.
Conclusion: Tα1 can improve the prognosis of patients with ACLF-HBV infection by inhibiting excess inflammatory reactions and reversing immune paralysis.

Abstract Submission No. 100055

A Change in Strategy for Filter Choice Leads to Improved Filter Retrieval Rates
Zhongzhi Jia1
1The Affiliated Changzhou Second People’s Hospital of Nanjing Medical University changzhou China
Objective: To assess whether a new strategy for the choice of inferior vena cava filter placed would improve filter retrieval rates at our institution.
Results: The study population included 26 patients with ISR and 26 control patients. Multivariable analysis demonstrated that stent-to-vascular (S/V) ratio (OR, 1.14; 95% CI, 1.00-1.29; P = .045), stent proximal position > 10 mm away from the SMA root (OR, 108.67; 95% CI, 3.09-3816.42; P = .010), and high oscillatory shear index (OSI) area (OR, 1.25; 95% CI, 1.02-1.52; P = .029) were predictors of ISR. In structural and fluid dynamics simulations, a stent proximal position near the abdominal aorta (AA) or entering into the AA reduced the contact area between the proximal struts of the stent and the vascular wall, alleviated the distal lumen over-dilatation.
Conclusion: S/V ratio, stent proximal position away from the SMA root, and high OSI area are independent risk factors for ISR in patients with SMAD undergoing stent placement. Deploying the proximal end of the stent near the AA or entering into the AA appears to improve the hemodynamic environment in the SMA lumen and ultimately reduce the risk of ISR.

Baicalein Alleviates ACLF by Promoting TREM2-dependent M2 Macrophage Polarization and Efferocytosis
Macrophage Polarization and Efferocytosis
Jia chen1, Qiongchi Zhang1, Zhipeng Li1, Zhexuan Deng1, Yeqiong Zhang2, Wenxiong Xu1,2, Liang Peng2

1Third Affiliated Hospital, Sun Yat-sen University Guangzhou China, 2Guangdong Key Laboratory of Liver Disease Research, The Third Affiliated Hospital of Sun Yat-sen University Guangzhou China

Background: Acute-on-chronic liver failure (ACLF) is a life-threatening syndrome characterized by sudden hepatic deterioration and systemic inflammation in the context of chronic liver disease. However, current therapeutic options are limited. This study investigates the potential of Baicalein, a natural flavonoid, to mitigate ACLF and explores the underlying molecular mechanisms.

Methods: Liver tissues from an ACLF mouse model, subjected to either Baicalein treatment or saline treatment, were collected. CD45+ immune cells were isolated via fluorescence-activated cell sorting and combined for single-cell RNA sequencing (total ten samples). Additionally, the study employed the BMDM cell line and mouse peritoneal macrophages for in vitro experiments. Furthermore, macrophage conditional TREM2 knockout mice were generated to confirm the initial findings. Lastly, peripheral blood samples were obtained from ACLF patients to quantify soluble TREM2 in serum and assess its correlation with the patients’ 28-day prognosis.

Results: The study demonstrates that Baicalein significantly alleviates liver injury in an ACLF mouse model. Single-cell sequencing results reveal a substantial increase in TREM2+ macrophages in the livers of the Baicalein-treated group, suggesting the pivotal role of TREM2+ macrophages in the process of Baicalein-mediated liver injury alleviation. Through further experiments, it is established that Baicalein-induced macrophage phagocytic receptor TREM2 is necessary for the efferocytosis of apoptotic hepatocytes and the polarization of M2 macrophages. Serum TREM2 levels are also significantly linked to the 28-day prognosis of ACLF patients.

Conclusion: In summary, this study highlights the potential of Baicalein as a therapeutic approach for ameliorating ACLF by promoting TREM2-dependent M2 macrophage polarization and efferocytosis.

Long-term efficacy and safety of three potent NAs in the treatment of HBV-ACLF: 144-week data

Yeqiong Zhang1,2, Wenxiong Xu1,2, Zhexuan Deng1, Lu Wang3, Xingrong Zheng1, Xi Pu1, Xuejun Li1, Liang Qi1, Shu0, Jing Lai0, Liang Peng1, Zhipeng Li3

1Department of Infectious Diseases, The Third Affiliated Hospital of Sun Yat-sen University Guangzhou China, 2Guangdong Key Laboratory of Liver Disease Research, The Third Affiliated Hospital of Sun Yat-sen University Guangzhou China, 3Department of Diagnostics, Second School of Clinical Medicine, Binzhou Medical University Yantai China

Background: There are no data on long-term prognosis and safety of tenofovir alafenamide (TAF), tenofovir disoproxil fumarate (TDF) and entecavir (ETV) in the treatment of HBV-related acute-on-chronic liver failure (HBV-ACLF). Here we report the 144-week results of the three NAs in the treatment of HBV-ACLF.

Methods: A total of 199 patients were included in this study. After PSM, 44 patients for each group were remained for further analyses. The original cohort, one patient in each group developed hepatocellular carcinoma. No serious drug-related adverse events were observed. The log-rank test indicated that no significance was found among the groups’ long-term survival rates (p = 0.118)(Fig A). Even in the subsets of with or without cirrhosis, there was still no significance (p = 0.338 and 0.052)(Fig B-C). There was no significant difference in the HBV DNA undetectable rate (Fig D) and liver function among the three groups, except for AST, which was significantly higher in the TDF group than in the ETV group at week 144 (p = 0.001). In terms of renal function, there was no significant difference among the three groups at other time points except that CR decreased and eGFR increased more significantly in the ETV group at week 48(Fig E-F).

Conclusions: There were no significant differences in the survival rate, incidence of hepatocellular carcinoma, efficacy and safety of the three NAs in the treatment of HBV-ACLF for 144 weeks.

CRRT in Children with Hepatitis A Virus associated Acute Liver Failure with Advanced Encephalopathy

Arjun Maria1, Nishant Wadhwa2, Anil Sachdeva2, Kanav Anand3
1Division of Pediatric Gastroenterology, Hepatology and Liver Transplant, Institute of Child Health, Sir Ganga Ram Hospital New Delhi India, 2Department of Pediatric Critical Care, Institute of Child Health, Sir Ganga Ram Hospital New Delhi India, 3Division of Pediatric Nephrology, Institute of Child Health, Sir Ganga Ram Hospital New Delhi India

Objective Effect of CRRT on survival in children with HAV associated ALF with HE grade III/IV

Methods Analysis of all children between January 2018 to April 2023. All children were offered CRRT, 21 agreed to CRRT and 14 who refused were treated with standard medical therapy (SMT) and included as controls. No liver transplantation.

Results: Thirty five analysed and 21 (60%) received CRRT. Baseline characteristics were comparable apart from ammonia, which was higher in the CRRT (p=0.001). Seven (33.3%) in CRRT and 3 (21.4%) in SMT group fulfilled Kings College Criteria for LT (p=0.445). In CRRT, 13 (61.9%) survived while in SMT group 7 (50%) survived (p=0.486). The survival time was 6.3 days in CRRT vs 7.29 days in the SMT group (p=0.769). On risk predictive analysis, failure to reduce ammonia by 30% by day 3 of therapy (p=0.001), inotrope requirement at day 3 (p=0.001), bilirubin at day 3 (p=0.001) and ammonia at day 3 (p=0.023) were associated with mortality. On Model 1 of Cox regression analysis, which included ammonia at day 3, bilirubin at day 3 and inotrope requirement at day 3, only bilirubin levels were associated with mortality (HR 1.157, p=0.04). Since bilirubin is reduced by CRRT, analysis performed again by including CRRT and inotrope in model 2. Inotrope requirement associated with 9.5 folds increase in mortality (HR 9.569, p=0.001), however CRRT was not significant

Conclusion: Increased survival in children who received CRRT, however it did not reach statistical significance. High bilirubin and persisting inotropic requirement at day 3 were associated with mortality.
than the SMT arm (p<0.05, each). The patients in OINT group had lesser number of hospitalizations (6 (17%) versus 16 (45.7%) (p=0.010) over the course of 3 months as compared to SMT group.

Conclusion: Outpatient intensive nutrition therapy has a significant impact on improving survival, frailty and disease severity of ACLF patients with a reduction in number of hospitalizations and supports the key role of nutrition in addition to standard medical treatment in ACLF patients.

ALTA: a simple nutritional prognostic score for patients with HBV-ACLF

Rui Song1, Xiaohao Wang1, Zhao Li2, Jiahe Tan3, Hongyu Wu1, Yunyi Tan1, Hanlu Li4, Teng Zeng5, Hong Ren1, Zhiwei Chen1

1The Second Affiliated Hospital of Chongqing Medical University Chongqing China, 2The Seventh People's Hospital of Chongqing Chongqing China, 3The First Affiliated Hospital of Chongqing Medical University Chongqing China, 4The Ninth People's Hospital of Chongqing Medical University Chongqing China, 5The Fifth People's Hospital of Chongqing Medical University Chongqing China

Background & Aims: Malnutrition, as a common but usually neglected complication, can increase the mortality in patients with hepatitis B virus-related acute-on-chronic liver failure (HBV-ACLF). The aim of this study was to develop a simple nutritional prognostic score to accurately predict the mortality in HBV-ACLF patients.

Methods: In this multicenter retrospective study, clinical data from 195 HBV-ACLF patients were used to develop a new prognostic score, and then was validated in two external cohorts.

Results: Four independent factors were significantly associated with 28-day mortality of HBV-ACLF patients and constituted a new prognostic score (ALTA score =2.216×age-2.283×lymphocyte count-1.902×total cholesterol-0.152×albumin-1.629). Notably, the AUROC of ALTA score for 28/90-day mortality (0.955/0.947) were significantly higher than those of three other ACLF prognostic scores (COSSH-ACLF II, 0.848/0.791; MELD, 0.607/0.596; MELD-Na, 0.602/0.582; all P=0.001), and three known nutritional scores (CONUT, 0.746/0.816; OPNI, 0.256/0.200; NRS-2002, 0.313/0.330; all P=0.001). Further classified ALTA score into three strata, the hazard ratios of mortality at 28/90 days were obviously increased in the intermediate-risk and high-risk groups than low-risk group (19.0/8.0 and 67.9/29.7). The negative predictive values of low-risk group and positive predictive values of high-risk group for 28/90-day mortality were 97%/78% and 94%/100%, respectively. Further optimized ALTA score into a scoring sheet (ALTA 2.0), it still exhibited excellent predictive ability. These results were then validated in two external cohorts.

Conclusion: ALTA, as a simpler and easier to use nutritional prognostic score for clinicians, can accurately predict short-term mortality of HBV-ACLF patients, hence, it might be used to guide clinical management.

Forecasting Initial 15-Day Mortality in Alcohol Related Acute On Chronic Liver Failure (ACLF)

Vivek Saini1, Sunil Kumar Dadhich1, Abhishek Yadav1, Rajendra Bhati1, Bobby Mitrolia1, Naveen Mehla1, Sewaram Choudhary1, Sabir Hussain1, Narendra Bhargava1

1Dr. Sampurnanand Medical College Jodhpur India

Background and Aim: The initial 15 days study in alcohol related ACLF is scarce, a period significant for mortality and liver transplantation feasibility. This study aims to fill this gap by conducting a detailed analysis of this timeframe.

Methods: Clinical and biochemical blood parameters of 227 alcoholic ACLF patients were collected. Patients were followed till 90 days or death with observations on 0, 4, 7, 15, 30, 45, 60, and 90 days. Statistical analysis was focused on 15 day mortality.

Results: Of 227 patients, 41% (94) died within 15 days. Baseline means of 15 day mortality versus survived showed significant difference in alcohol intake (198g/day v 144g/day), serum creatinine (2.2mg/dl v 1.6mg/dl), lactate (2.8mmol/l v 1.8mmol/l) and AARC score (10.7 v 9.4).

Significant hazard ratios (HR) on multivariate cox regression of categorical blood parameters were creatinine (<0.7mg/dl v >1.5mg/dl, HR-0.44), INR (<1.8 v >1.8, HR-0.47), lactate (<1.8mmol/L v >1.8mmol/L, HR-0.42), neutrophil counts (<80% v >80%, HR-0.43). Those consuming <200g/day of alcohol had 70% less mortality to those with >300g/day. Among the prognostic scores, AARC score (≤7 v >10, HR-0.10) and SIRS (present v absent, HR-9.5) were key determinants. In decision tree analysis SIRS presence alone leads to 65% mortality, SIRS with lactate >1.4mmol/l resulted in 75% deaths, and trio combination of SIRS, lactate >1.4mmol/l , and alcohol intake >200g/day leads to 100% mortality.

Conclusions: Alcoholic ACLF have 41% initial 15 Day mortality. The combination of SIRS presence, lactate level >1.4mmol/l, and alcohol intake >200g/day was linked to 100% deaths.

XBP1 mediating NFκBp65 promotes macrophage derived inflammation via MT2 transcript in liver IRI

Jianhua Rao1, Zeng Wang1, Fei Yu1, Junda Li1, Wenzhu Li1, Zhengfeng Xuan1, Yongquan Chi1, Feng Zhang1, Liming Tang2, Feng Cheng3

1Hepatobiliary Center of The First Affiliated Hospital, Nanjing Medical University, Research Unit of Liver Transplantation and Transplant Immunology, Chinese Academy of Medical Sciences, Nanjing 210029, China Nanjing China, 2Center of Gastrointestinal Disease, The Affiliated Changzhou NO.2 People's Hospital of Nanjing Medical University, Changzhou 213003, China Changzhou China

Background: XBP1, the most conserved transcription factor of endoplasmic reticulum stress, plays important roles in physiological and pathological settings. Its activity has profound effects on disease progression and prognosis. We aimed to investigate the role of XBP1 in macrophage-originated sterile inflammation during liver ischemia/reperfusion injury (IRI).

Methods: Macrophage XBP1 expression and liver injury were analyzed in patients undergoing ischemia-related hepatocyte. Then, we created a myeloid-specific XBP1-knockout (XBP1M-KO) strain to study function and mechanism of XBP1 on macrophage-derived sterile inflammation in murine liver IRI model with In-vitro parallel research. Macrophages co-cultured with hypoxia-treated hepatocytes were applied to investigate impact of XBP1 in vitro. We also analyzed RNA sequencing and databases for potential XBP1 target gene by CUT&RUN and luciferase reporter assay.
Results: Clinically, macrophage XBP1 expression significantly increased in ischemic liver tissues and positively correlated with liver injury after heptectomy. Less hepatocellular damage was presented in XBP1M-KO mice than XBP1-proficient controls based on serum biochemistry, pathology, ROS and inflammation. In vitro, XBP1 deficiency inhibited sterile inflammation and migration in macrophages co-cultured with hypoxia-treated hepatocytes. Analysis of RNA sequencing and databases determined Metallothionein 2 (MT2) as an XBP1 target gene, negatively regulated by binding with its promoter. XBP1 deficiency increased MT2 expression and IKBa expression, but inhibited NF-xB-p65 phosphorylation. MT2 inhibition and NF-xB activation markedly neutralized XBP1M-KO-related benefits by promoting sterile inflammation during liver IRI.

Conclusion: XBP1 promotes macrophage-originated sterile inflammation, increases liver IRI by binding to the MT2 promoter, and regulates MT2/NF-xB pathway, providing a potential therapeutic target for liver IRI.

Biomarker discovery, validation & pathways in infection related acute-on-chronic liver failure

Pratibha Garg1, Nipun Verma1, Arun Valsan1, Vivek Sarohi2, Trayambak Basak1, Parminder Kaur1, Shreya Singh1, Arka De1, Madhumita Premkumar1, Sunil Taneja1, Ajay Duseja1, Virendra Singh1

1Department of Hepatology, Postgraduate Institute of Medical Education and Research, Chandigarh, India Chandigarh India, 2School of Basic Sciences, Indian Institute of technology Mandi, HP India, 3Department of Medical Microbiology, Postgraduate Institute of Medical Education and Research, Chandigarh, India Chandigarh India

Objective: Evaluating infections in the context of acute-on-chronic liver failure (ACLF) presents a formidable challenge. This study employs untargeted proteomics to uncover protein signatures and pathway perturbations associated with infections in ACLF.

Design: We prospectively enrolled 231 ACLF patients (92.6% males, mean age 42.1 years, 65% alcoholic hepatitis), both with and without bacterial/fungal infections. Untargeted proteomics was performed on plasma samples from 84 patients (discovery cohort), followed by biomarker discovery and validation using differential expression, discriminant analysis, machine learning, and ELISA in 147 patients. Perturbed pathways between infected and non-infected groups were analyzed.

Results: Infection-positive patients exhibited elevated leucocyte count, procalcitonin, organ failures, severity scores, and a 30-day mortality of 81.4% vs. 6.6% (p<0.001 each). Among the 516 identified proteins, 27 were upregulated and 38 downregulated in infections (adjusted-p<0.05). Validation yielded a four-protein panel (LGALS3BP, PLTP, CFP, GPX3) classifying infections with AUC 0.854 (0.787-0.922), retaining significance after adjusting for disease severity and inflammation. A PACIFY model, integrating three proteins (LGALS3BP, PLTP, GPX3), procalcitonin, CLIF-C OF, and leukocytosis/leucopenia, yielded AUC 0.957 (0.927-0.986), accuracy 89.1%, sensitivity 90.2%, and specificity 99.7% for infection diagnosis. PACIFY outperformed procalcitonin, SIRS, WBC, NLRI, neutrophil%, and composite models (p<0.001). Pathway analysis unveiled diverse perturbations including impaired pathogen-response, reduced-phagocytosis, neutrophil extracellular traps, complement functions, hypocoagulation and hypofibrinolysis, dysregulated carbohydrate metabolism and autophagy, with heightened cell death and proteolysis.

Objective Prognostic Nutritional Index (PNI) is an index that can reflect nutritional status and immune function of patients and calculated from the serum albumin concentration and the total number of peripheral lymphocytes. This study aims to explore the predictive value of PNI on infectious complication in patients with acute-on-chronic liver failure (ACLF).

Methods Two hundred and twenty patients with ACLF hospitalized in the First Affiliated Hospital of Xi’an Jiaotong University were selected who were divided into infection group and non-infection group based on whether they were infected in hospital. Differences in clinical data and laboratory indicators were compared between the two groups. Logistic regression analysis was used to select the influencing factors related to infectious complication. Receiver operating characteristic curve (ROC) was applied to evaluate the predictive value of PNI on infection.

Results: (1) In patients with ACLF, there were 152 and 68 patients in infection group and non-infection group respectively. Ascites, hepatorenal syndrome, PNI, ALB and so on were statistical differences between the two groups (P<0.05). (2) Among 152 infectious patients, the common sites of infection were abdominal infection and pulmonary infection, with an incidence of (113/198, 57.07%) and (58/198, 29.29%). (3) The results of logistic multivariate analysis showed that low PNI, ascites and hepatorenal syndrome were risk factors for infectious complication. When PNI≤ 40.625, it has a better prediction effect on infectious complication in patients with ACLF, with sensitivity of 0.842 and specificity of 0.412.

Conclusion: The low PNI is an independent risk factor for developing infection in patients with ACLF. When PNI≤40.625, it can predict infectious complication in patients with ACLF.

Hepatitis E virus infection portends high mortality in patients with acute-on-chronic liver failure

Guan-Huei Lee1, 2, Sabrina ZX Quek1, Seng Gee Lim1, 2, Mark Muthiah1, 2, Ashok Choudhury3, Vinod Arora3, Mohd Rela4
Established an ACLF mouse model treated with SDX and HS.

Methods: Prospectively collected data of 5612 ACLF patients from 25 countries in the AARC database between 2007 and 2021 was studied. The data analysed included demographic profile, severity of liver disease (MELD, AARC score), chronology of organ failure development, treatments and outcomes. Statistical analyses were carried out using RStudio version 2023.09.01 and OpenEpi version 3.01.

Results: The study included 340 HEV IgM-positive patients (6.06% of total cohort) and 5272 non-HEV patients who were hospitalised for ACLF. Compared with non-HEV patients, HEV-positive patients have similar demographic profile (age, gender, and chronic liver disease) and disease severity at baseline (MELD 29.9 and AARC score 9.62). However, HEV patients have significantly higher 90-day mortality (54.7% vs. 48.1%, p=0.019), number of organ failures by day 4 (median of 2 vs. 1, p=0.001) and progression (time to death: 11 vs. 13 days, p=0.012).

Conclusions: HEV infection is associated with higher mortality rate and number of organ failures in ACLF patients. This may be related to the lack of specific therapy for HEV infection.

Syndecan-1 improves ACLF by promoting liver regeneration and attenuating hepatocytes apoptosis

Xiaoli Zhang1,2, Yali Zhao1,2, Shan Fu1,2, Juan Li1,2, Tianzhi Ni3, Lingyun Xu4,5, Ruojing Wang6, Qiao Zhang1,2, Weicheng Xu4, Taoa Zhai2, Yiling Zhao7, Yinghe He8

1Department of Infectious Diseases, Xi’an Jiaotong University Xi’an China, 2National Key Research and Development Program of China, 3Department of Hepatology, Xi’an Jiaotong University, Xi’an China, 4Shaanxi Key Laboratory of Molecular Parasitology and International Joint Research Laboratory of Malaria and Other Infectious Diseases, Xi’an Jiaotong University, Xi’an China, 5Department of Gastroenterology, First Affiliated Hospital of Xi’an Jiaotong University, Xi’an China, 6Department of Hepatology, Xi’an Jiaotong University, Xi’an China, 7Department of Hepatology, Xi’an Jiaotong University, Xi’an China, 8Department of Hepatology, Xi’an Jiaotong University, Xi’an China

Background and Aims: Acute-on-chronic liver failure (ACLF) has a high short-term mortality rate. Syndecan-1 (SDC-1) is a major molecule of heparan sulfate proteoglycans present on healthy liver tissue, which can be shed from the cell surface. The core proteins of SDC-1 carry heparan sulfate (HS) chains, and sulodexide (SDX) is a heparinoid compound. Thus, we aimed to assess diagnostic, prognostic and therapeutic efficacy of SDC-1 and its side chains in ACLF patients.

Methods: Serum SDC-1 was examined in 26 healthy controls, 34 patients with chronic hepatitis, 38 with liver cirrhosis, and 101 ACLF patients by ELISA. And a prospective cohort of 101 ACLF patients was followed up to develop a novel prognostic score. Furthermore, we established an ACLF mouse model treated with SDX and HS.

Results: Serum levels of SDC-1 in ACLF patients were obviously increased compared to healthy controls (P < 0.0001). According to our 90 days of clinical observations, non-survived ACLF had markedly higher baseline serum SDC-1 levels than survivors (P < 0.05). A novel prognostic model (UIAS = 0.076 * Age + 0.001 * SDC-1 + 1.454 * INR + 2.854 * UGIB - 12.165) was developed for ACLF. In a cell model of acute liver injury, overexpression of SDC-1 significantly increases expression of proliferating cell nuclear antigen (PCNA) and cyclinD1. Furthermore, in a mouse model, we found that SDX and HS significantly attenuated ACLF, which may by promoting liver regeneration and restraining capase3-related apoptosis. Furthermore, Collectively, our findings suggest that SDC-1 can potentially serve as a predictive biomarker for ACLF prognosis and may represent a promising therapeutic target for relieving severe liver injury.

Activating cholinergic pathway attenuates Liver injury by inhibiting MLKL-mediated necroptosis

Shan Fu1, Tianzhi Ni1, Xiaoli Zhang1, YaLi Feng1, Ruojing Wang2, YingLi He1,2, YingRen Zhao0, JinFeng Liu1,2

1Department of Infectious Diseases, The First Affiliated Hospital of Xi’an Jiaotong University, Xi’an China, Shaanxi China, 2Shaanxi Clinical Medical Research Center of Infectious Diseases, Xi’an China

Background: The function of cholinergic anti-inflammatory pathway (CAP) in acute liver failure (ALF) with inflammatory storm remains indefinite. Mixed lineage kinase domain-like pseudokinase (MLKL), a key terminal effector of necroptosis, plays a crucial role in regulating liver inflammation. Investigation about CAP regulation on necroptosis would enrich our understanding over cholinergic anti-inflammatory mechanism.

Approach and Results: Co-injection of Lipopolysaccharide and D-galactosamine were used to establish the model of ALF. PNU-282987 was used to activate the CAP. Liver biopsy specimens and patients’ serum from liver failure patients were also analyzed. We confirmed that activating the CAP alleviated hepatoocyte destruction, accompanied by a significant decrease in hepatocyte apoptosis, pro-inflammatory cytokines, and NLRP3 inflammasome activation. Moreover, hepatic necroptosis and serum MLKL levels were induced in ALF and MLKL levels were positively correlated with the extent of liver damage and the expression of proinflammatory markers (IL-6, IL-1β, TNF-α). MLKL was colocalized with macrophage marker F4/80 in livers. Mechanistically, MLKL deletion also remarkably decreased pro-inflammatory cytokines and inhibited polarity shift toward inflammatory macrophages. Furthermore, Activating the CAP inhibits MLKL-mediated necroptosis and downregulated markers of inflammatory macrophages in vivo and in vitro. Finally, we revealed that the levels of serum MLKL were elevated in patients with liver failure and closely correlated with clinical course. Increasing hepatic MLKL were also confirmed in patients.

Conclusion: Together, these data indicated that activation of the CAP attenuates Liver injury by inhibiting macrophage-derived MLKL-mediated necroptosis and regulating macrophage polarization and function. Targeting MLKL might be a potential therapeutic way to treat ALF.

Niclodamide inhibits Macrophage Ferroptosis against LPS/D-GaN-induced Acute Liver Failure

Abstract Submission No. 100929

O-0837
Xiao Zhong1−2, Ruochan Chen1−2, Xue-Gong Fan1−2
1Department of Infectious Diseases, Hunan Key Laboratory of Viral Hepatitis, Xiangya Hospital, Central South University Changsha China, 2National Clinical Research Center for Geriatric Disorders, Xiangya Hospital, Central South University Changsha China

Acute liver failure (ALF) is a life-threatening liver disease with a high mortality rate, and the identification of specific therapeutic agents represents a crucial clinical challenge. Although oxidative stress and inflammatory responses within the liver play pivotal roles in the pathogenesis of ALF, the precise regulatory mechanisms remain elusive. Ferroptosis, a form of programmed cell death, is closely associated with oxidative stress and inflammation. Applying the strategy of “old drugs with new uses” and bioinformatics analysis, we screened for potential agents and identified niclosamide, an anthelmintic drug. Niclosamide dose-dependently improved survival rates and protected mice from LPS/D-galactosamine-induced liver injury. In vitro, niclosamide affected macrophage proliferation and the production of inflammatory mediators in response to LPS without exerting a direct protective effect on hepatocytes. Subsequent studies revealed that niclosamide could inhibit macrophage ferroptosis, particularly M2 macrophage ferroptosis, in vivo. Consistently, niclosamide suppressed macrophage ferroptosis without affecting hepatocytes. Based on these findings, we propose the scientific hypothesis that niclosamide targets hepatic macrophage ferroptosis to inhibit the development and progression of ALF.

Comparison of 28 Day Survival of Patients with ALF and ACLF treated with DPMAS
Jan Axel Yusi1, Pamela Angulo1, Ian Homer Cua1, Ma. Kristina Alolod1
1St. Luke’s Medical Center Quezon City Quezon City Philippines

Objectives: The study aims to determine the clinical outcomes of patients who underwent DPMAS.

Methods: This is a cross-sectional analytic study that retrospectively analyzed 36 adult patients, 14 with ALF and 22 with ACLF who received DPMAS in 2 Tertiary Hospitals in the Philippines.

Results: A total of 36 adult patients on DPMAS were included, 30 were on DPMAS and 6 were on DPMAS + Plasma Exchange(PE). Of the 30 patients who underwent DPMAS, 14 have ALF and 16 have ACLF. All Six patients who underwent DPMAS and PE have ACLF. The median age was 59(QQR 17.25) and majority are males(78%). The most common etiologies for ALF were hyperperfusion, 4(11%), and Drug-induced, 4(11%), while hepatocellular carcinoma, 10 (28%), followed by Chronic Hepatitis B, 9 (25%) are common etiologies for ACLF. Majority had Child Pugh Class C and Grade 3 Hepatic Encephalopathy. Total bilirubin declined after DPMAS for both ALF (17.845 to 11.485, p= 0.646 ) and ACLF (16.685 to 12.02, p=0.118 ). 28-day Survival rate in ALF on DPMAS is 18%, while ACLF patients on DPMAS is 30% (p=0.854). There was no difference between survival distributions of ALF=DPMAS, ACLF=DPMAS and ACLF=DPMAS+PE(p=0.844) using the Kaplan Meier method.

Conclusion: DPMAS and DPMAS+ PE improved the clinical and laboratory parameters in both ALF and ACLF. A larger cohort of patients, however, is needed to ascertain its clinical significance.

Exosomes from senescent hepatocytes activate HSCs and protect against acute liver failure by ITGA5
Yali Feng1, Shan Fu1, Xiaoli Zhang1, Juan Ji1, Tianzhi Ni1, Ruojing Wang1, Jinfeng Liu1, Yingren Zhao1, Yingli He1
1Department of Infectious Diseases, the First Affiliated Hospital of Xi’an Jiaotong University, Xi’an Jiaotong University Xi’an China

Background: Cell senescence markers, such as p21, P16, and p53, were increased in mice with acute liver failure. Senescent hepatocytes, induced by etoposide, secreted more exosomes than non-senescent cells. Exosomes were isolated from the conditional media of senescent (Sen) or non-senescent (NSen) hepatocytes by differential ultracentrifugation and identified by electron microscope and western blots.

Results: Cellular senescence markers, such as p21, P16, and p53, were increased in mice with acute liver failure. Senescent hepatocytes, induced by etoposide, secreted more exosomes than non-senescent cells. Exosomes derived from Sen-hepatocytes promote migration, proliferation, and activation of HSCs. Proteomic characterization of exosomes

TPO promotes hepatocyte regeneration by elevating platelets in rats with acute liver failure
Jing Liang1, Fengzheng Han2, Li Jing1, Ying Luo1
1Tianjin Third Central Hospital Tianjin China, 2Tianjin Jinnan Hospital Tianjin China

Aim: To investigate the role of platelets and recombinant human thrombopoietin (rhTPO) on liver regeneration in rats of acute liver failure (ALF).

Methods: A rat model of acute liver failure was constructed by injection of D-amino galactose(D-GalN). The experimental rats were randomly divided into rhTPO group (n=20) and control group (n=20), which were given rhTPO 15µg/Kg or saline for 5 days before D-GalN injection respectively. Liver tissue and blood samples were taken from rats at 6, 24 and 72 hours after the construction of an acute liver failure model after D-galactose injection in both groups. Hepatic histopathological changes and Ki67 were observed in both groups. The survival, liver function, serum HGF level were compared between the two groups after injection of D-GalN. Cell proliferation and cell apoptosis were analyzed by BrdU and TUNEL.

Results: Before D-GalN injection, the PLT counts and liver weight of rhTPO group were remarkably higher than that in the control group (P<0.01). After injection of D-GalN, the rhTPO group had significantly lower ALT levels at 6 and 24 hours and significantly lower TBI levels at 72 hours as well as the control group (P<0.05). The proportion of TUNEL-positive cells in liver tissues in the rhTPO group was lower than that in the control group (P<0.01), the serum HGF levels and the proliferation index of Ki67 and the proportion of BrdU-positive cells were significantly higher than that in the control group (P<0.05).

Conclusion: TPO significantly elevated PLT counts in D-amino galactose induced ALF rats. Platelet elevation induced by rhTPO promoted recovery of liver function, reduced hepatocyte apoptosis and increased liver regeneration in ALF rats.

Exosomes from senescent hepatocytes activate HSCs and protect against acute liver failure by ITGA5

Ruojing Wang1, Jinfeng Liu1, Yingren Zhao1, Yingli He1
1Department of Infectious Diseases, the First Affiliated Hospital of Xi’an Jiaotong University, Xi’an Jiaotong University Xi’an China

Aim: To investigate the role of platelets and recombinant human thrombopoietin (rhTPO) on liver regeneration in rats of acute liver failure (ALF).

Methods: A rat model of acute liver failure was constructed by injection of D-amino galactose(D-GalN). The experimental rats were randomly divided into rhTPO group (n=20) and control group (n=20), which were given rhTPO 15µg/Kg or saline for 5 days before D-GalN injection respectively. Liver tissue and blood samples were taken from rats at 6, 24 and 72 hours after the construction of an acute liver failure model after D-galactose injection in both groups. Hepatic histopathological changes and Ki67 were observed in both groups. The survival, liver function, serum HGF level were compared between the two groups after injection of D-GalN. Cell proliferation and cell apoptosis were analyzed by BrdU and TUNEL.

Results: Before D-GalN injection, the PLT counts and liver weight of rhTPO group were remarkably higher than that in the control group (P<0.01). After injection of D-GalN, the rhTPO group had significantly lower ALT levels at 6 and 24 hours and significantly lower TBI levels at 72 hours as well as the control group (P<0.05). The proportion of TUNEL-positive cells in liver tissues in the rhTPO group was lower than that in the control group (P<0.01), the serum HGF levels and the proliferation index of Ki67 and the proportion of BrdU-positive cells were significantly higher than that in the control group (P<0.05).

Conclusion: TPO significantly elevated PLT counts in D-amino galactose induced ALF rats. Platelet elevation induced by rhTPO promoted recovery of liver function, reduced hepatocyte apoptosis and increased liver regeneration in ALF rats.

Abstract Submission No. 101255
O-0840
revealed that ITGA5 was overexpressed in exosomes derived from Sen-hepatocytes. ITGA5 was also increased in Sen-hepatocytes and liver with ALF mice, which was regulated by mTORC1 in cellular senescence condition. ITGA5 silencing in HSCs reduced HSC activation and migration by inhibiting Smad2 phosphorylation. Pharmacologic inhibition of ITGA5 using ATN-161 exacerbated liver failure by inhibiting HSC activation and impairing liver structure.

**Conclusion:** ITGA5-enriched exosomes derived from senescent hepatocytes activate hepatic stellate cells via regulation of Smad2 signaling, which maintains the liver architecture to prevent collapse during acute liver failure.

**Background:** Liver failure is a life-threaten syndrome and cause high short-term mortality. Double plasma molecular adsorption system (DPMAS) is one of the available artificial liver support systems which its efficiency for chronic liver disease (CLD) patients with liver failure remains controversial.

**Methods:** A prospective, multicenter and cluster-controlled study was conducted (NCT05129904) and 57 tertiary hospitals were recruited and allocated to the DPMAS treatment clusters (n=28) and standard medical treatment (SMT) clusters (n=29). Outcomes included disease progression, survival, death and liver transplantation and safety of DPMAS therapy. Twelve-months is required for each participant to complete post-discharge follow-up.

**Results:** In total, 648 liver failure patients were enrolled in DPMAS group and 615 patients in SMT group. MELD score was comparable between these two groups (24±5 vs. 24±6, p=0.984). For the DPMAS group, 31.9% patients had 2 DPMAS treatment sessions and 77.1% of the initial DPMAS treatment was with subsequent plasma exchange. Unfractionated heparin was the most common anticoagulants used in DPMAS treatment. The total bilirubin, ALT and CRP levels were all significantly improved after the initial DPAMS therapy. The 28-day transplant-free mortality was much lower in DPAMS group than SMT group (15.7% vs. 20.0%, p=0.048). Allergy (3.7%) and dialyzer coagulation (3.2%) as well as the arterial hypotension (2.9%) were the common adverse events during DPMAS treatment.

**Conclusions:** DPMAS treatment for CLD patients with liver failure can significantly improve the liver function markers and the 28-day mortality. DPMAS therapy was associated with few adverse events and its safety is confirmed.

**Clinical Characteristics and Risk Factors of End-Stage Liver Disease Complicated by Infections**

Qin NING¹, Wei Liu¹, Youqin Yan², Xiaolin Zhou³, Yi Li⁴, Wei Hu⁵, Yue Chen⁶, Xiujie Chen⁷, Jianjun Zhang⁸, Lyuyue Xu⁹, Jun Zhu¹⁰, Tao Chen¹

¹Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology Wuhan China, ²Wuhan Seventh Hospital Wuhan China, ³The First College of Clinical Medical Science, China Three Gorges University Yichang China, ⁴Wuhan Puren Hospital, Wuhan University of Science and Technology Wuhan China, ⁵Wuhan No. 1 Hospital, Wuhan Wuhan China, ⁶Taite Hospital, Hubei University of Medicine Shiyuan China, ⁷Xiangyang Central Hospital, Hubei University of Arts and Science Xiangyang China, ⁸The Third People’s Hospital of Hubei Province Wuhan China, ⁹General Hospital of The Yangtze River Shipping Wuhan China, ¹⁰Xian’ning Central Hospital Xian’ning China

**Background:** Bacterial or fungal infection is one of the most frequent complications for end-stage liver disease (ESLD) patients. However, clinical characteristics and risk factors in ESLD with bacterial or fungal infection have not been fully elucidated.

**Methods:** ESLD patients from 14 tertiary hospitals were involved in this retrospective cohort study from January 2012 to December 2018 in central China. The clinical characteristics and risk factors in ESLD with bacterial or fungal infection were analyzed.

**Results:** Out of all 1208 ESLD patients, 565 (46.8%) were complicated by bacterial infection and 16 (1.3%) were complicated by fungal infection. Spontaneous bacterial peritonitis was the most common type of infection (51.5%), followed by pneumonia (43.7%), urinary tract infection (7.9%) and bacteremia (2.8%). Seventy-two samples showed positive culture results, among which 28 (38.9%) were gram-positive bacteria, 28 (38.9%) were gram-negative bacteria and 16 (22.2%) were fungus. ESLD patients with bacterial or fungal infection both showed higher level of white blood cell and procalcitonin, severer liver and coagulation dysfunction, and more likely to develop ascites, hepatorenal syndrome, hepatic encephalopathy, upper gastrointestinal bleeding, and hepatopulmonary syndrome than those without. Bacterial infection was a mortality risk factor for patients with ESLD and acute on chronic liver failure (ACLF) was an independent predictor for poor outcomes in ESLD with bacterial or fungal infection.

**Conclusions:** Bacterial infection was an independent risk factor of mortality of ESLD. Homogeneity and heterogeneity in epidemiology, clinical characteristics and risks of mortality were shown among different entities of ESLD with bacterial or fungal infections.

**Fulminant Hepatic Failure In Pregnancy Challenges, Etiology, Management And Its Associated Mortality**

Hanisha Hemnani¹, Nazish Butt²

¹Altamash General Hospital Karachi Pakistan, ²Jinnah Postgraduate Medical Center Karachi Pakistan

**Background:** FHF in pregnancy negatively maternal affects and fetal outcomes, which depend on the etiology, timely diagnosis, prompt management, and early referral equipped medically to a center for managing obstetric complications.
The study aimed to determine the challenges, etiology, management, and associated mortality in pregnant fulminant hepatic failure (FHF) patients.

**Methodology:** A cross-sectional study at the Department of Gastroenterology, JPMC, Karachi, Pakistan. All pregnant patients with FHF, age ≥16 years recruited were investigated for acute viral serology, complete blood count, function function tests, tests, liver renal serum MELD creatinine, score parameters and King’s college criteria (KCC) parameters.

**Results:** We have enrolled 47 patients up till now with a mean age of 25.14 ± 8.32 years. The KCC criteria cut-off point was reached in a total of 40 (85.10%) patients (out of 47) of which 30 (75%) patients died.

**Conclusion:** We conclude that for pregnant women, diagnosis should consider early hepatitis E as the usual cause of FHF in our case with consultation termination of pregnancy. The Management protocols need to be individualized for each case keeping in mind the risk versus benefit to both the mother and the fetus.

**Role of plasma-derived exosomal IncRNA in regulating the systemic inflammatory response in HBV-ACLF**

**QI HUANG1,2,3, JING LI1,2,3, XIN ZHONG1,3, LANFEN PENG1,3, MENGQING MA6, MINLING LV1,3, RUI HU0, WEI ZHANG1,3, XINFENG SUN8, WENFENG MA6, ZHIYI HAN6, JINYU YI0, JIALING SUN8, XIAOZHOU ZHOU1,2,3**

1Shenzhen Traditional Chinese Medicine Hospital, Department of Liver Disease SHENZHEN China, 2Macau University of Science and Technology, Faculty of Chinese Medicine Macao China, 3The Fourth Clinical Medical College of Guangzhou University of Chinese Medicine, Department of Liver Disease, Shenzhen China

This study investigated the RNA characteristics related to disease progression in hepatitis B virus (HBV)-related acute-on-chronic liver failure (ACLF) and the molecular mechanisms involved in immune regulation. Plasma exosomal long noncoding RNA (lncRNA) of 5 healthy volunteers, 5 patients with chronic hepatitis B (CHB) flares, and 8 patients with HBV-ACLF was characterized using RNA sequencing analysis. Exosomal differentially expressed IncRNA (DEIncRNA) was screened using differential analysis and protein-protein interaction, and competing endogenous RNA network maps were constructed. Immune-related mRNAs mediated by DEIncRNA regulation were identified using immunology databases. Their expression levels were verified by RNA sequencing samples of 5 patients with CHB flares, and 5 patients with HBV-ACLF. Bioinformatics analysis was used to predict the potential biological functions of the DEIncRNA. A newly identified IncRNA, MSTRG.38026, was differentially expressed in HBV-ACLF plasma exosomes. We predicted that MSTRG.38026 binds to hsa-miR-22-3p to regulate 107 immune-associated mRNAs. GO enrichment and KEGG pathway analysis suggested possible biological functions associated with immune-related mRNAs mediated by MSTRG.38026. The expression of TFKC(DAK), TGFBR1, and NFA53 was significantly downregulated in high-throughput sequencing validation. This work is the first to characterize the IncRNA profile of exosomes generated from the plasma of patients with HBV-ACLF.

**The role of L3-PMI in the prognostic evaluation of patients with acute-on-chronic liver failure**

**Qing Ye1,2,3,4, Junjun Cai1,2,3,4, Junqing Yan1,2,3,4, Rong Lv5**

1Department of Hepatology of The Third Central Hospital of Tianjin, China Tianjin China, 2The Third Central Clinical College of Naikai University Tianjin China, 3Tianjin Key Laboratory of Extracorporeal Life Support for Critical Diseases of Tianjin Tianjin China, 4Institute of Hepatobiliary Disease Tianjin China, 5Radiology Department of Tianjin Third Central Hospital Tianjin China

**BACKGROUND:** Sarcopenia is closely related to the prognosis of the patients with end-stage liver disease. However, there are still lack of simple and practical evaluation indicators in clinical practice. The purpose of this study is to explore the applicable value of the third lumbar psoas muscle index (L3-PMI).

**METHODS:** We retrospectively studied the data of 140 patients who met the ACLF diagnostic criteria for hepatitis B cirrhosis. Analyze the patient’s L3-PMI and clinical characteristics and prognosis.

**RESULTS:** The 140 patients were divided into the survival group with 102 cases and the death group with 38 cases according to their 90-day survival status. The L3-PMI value of patients in the death group was 4.89 ± 1.42 cm²/m², significantly lower than that in the survival group (5.94 ± 1.24 cm²/m²) (P < 0.001). In addition, 33 ACLF patients with hepatic encephalopathy (HE) had an L3-PMI value of 5.17 ± 1.49 cm²/m² which was significantly lower than that of 107 patients without LPS promotes inflammation via proteasomal degradation of Atg13 in HSCs during ACLF

**Zhen Tian1**

1The First Affiliated Hospital of Xi’an Jiaotong University Xi’an China

**Background:** Inflammation plays a critical role in the progression of ACLF. Atg13 is a vital regulatory component of ULK1 complex. Hepatic stellate cells (HSCs) were considered non-inflammatory cells and contributed only to hepatic fibrosis in the past. Recently, some studies found that HSCs can secrete inflammatory cytokines. Autophagy has been shown to regulate inflammation, it is unclear whether ubiquitin (Ub)-proteasome system (UPS) is involved in inflammatory responses in HSCs during ACLF.

**Methods:** Clinical data were collected from ACLF patients. The expression of Atg13 was assessed by rt-PCR and western blotting. Atg13 was knocked down by si-RNA in LX2 cells. A co-immunoprecipitation assay was used to detect protein binding and poly-ubiquitination of Atg13. In vitro tests with LX2 cells were performed to explore the effects and regulation of p38 MAPK, Atg13, UPS, autophagy, and inflammation.

**Results:** We evaluated the role of Atg13 in HSCs inflammation and explored the underlying mechanisms. Inflammatory factors are up-regulated via activation of p38 MAPK and inhibition of autophagy in LX-2 cells. Expression of Atg13 was decreased in LPS-incubated LX2 cells. Atg13 knockdown markedly inhibited autophagy and promoted LPS-induced inflammation in LX2 cells. Our results also showed that LPS induced depletion of Atg13 via UPS, which was p38 MAPK dependent.

**Conclusions:** LPS induces proteasomal degradation of Atg13 via p38 MAPK, participating in the aggravation of LPS-induced autophagy inhibition and inflammatory responses in LX2 cells. Atg13 serves as a mediator between autophagy and proteasome. Modulating Atg13 or proteasome activity might be a novel strategy for treating HSCs inflammation.
HE (P = 0.020). Draw the ROC curve of L3-PMI predicting death by gender. The area under the ROC curve for males was 0.726, the cut-off value was 5.02, the sensitivity and specificity were 85% and 50% respectively. The area under the ROC curve for females was 0.774, and the cut-off value was 4.60. The sensitivity and specificity were 50% and 100% respectively.

**CONCLUSION:** L3-PMI has important clinical application value for evaluating the prognosis of ACLF patients related to hepatitis B cirrhosis.

**Activation of hepatocyte p53 triggers acute liver failure with multiple organ injury.**

Jihyun Sung1, Hayato Hikita1, Yuki Makino1, Seiya Kato1, Yoichi Sasaki1, Kenji Fukumoto1, Kazuhiro Murai1, Kunimaro Furuta1, Akira Nishio1, Takahiro Kodama1, Tomohide Tatsumi1, Tetsuo Takeraha1

1Osaka university Suita Japan

p53 is the major cellular regulator, which controls proliferation and cell death. Meanwhile, its impact on acute liver failure (ALF) remains unknown. This work aims to study the role of p53 on ALF. In Gene Expression Omnibus database, human hepatic p21, a p53 target, was up-regulated in fulminant hepatitis liver compared with normal liver. C57B6J mice administered with acetaminophen or concanavalin A showed upregulation of p53 protein in the liver. We knocked out Mdm2, a negative regulator of p53, and inducibly and hepatocyte-specifically by tamoxifen administration in mice (Mdm2Δhep mice). Mdm2Δhep mice showed activation of p53 signaling with extensive cell death in hepatocyte, and elevated serum ALT and bilirubin. Also multiple organ injury was noted as the increase of TUNEL-positive cell death. Meanwhile, its impact on acute liver failure (ALF) remains unknown. Also non-CF. Septic and haemorrhagic shock were the main causes of CF. Age, white blood cell counts and international normalized ratio were identified as independent risk factors for CF development during hospitalization. The survival rate in HBV-ACLF patients with CF undergoing LT was significantly higher than that in those without LT (28/90/360-day: 62.9%/54.3%/54.3% vs. 6.4%/4.8%/4.8%, p <0.001). Propensity score matching analysis confirmed these results (28/90/360-day: 62.9%/54.3%/54.3% vs. 7.1%/7.1%/7.1%, p <0.001). Stratification analysis further showed that CF patients with INR <3.5 had a higher 360-day post-LT survival rate.

**Conclusions:** HBV-ACLF patients with CF exhibited a poor prognosis, and LT significantly improved their survival. Patients with INR <3.5 had a higher survival benefit from LT. These findings can help refine candidate selection for LT in clinical practice.

**Longitudinal single-cell profiling unveils distinct immune traits linked to ACLF progression**

Jun Li1, Xi Liang2, Qian Zhou1, Jinjin Luo1, Jiaqi Li3

1State Key Laboratory for Diagnosis and Treatment of Infectious Diseases, National Clinical Research Center for Infectious Diseases, National Medical Center for Infectious Diseases, The First Affiliated Hospital, Zhejiang University School of Medicine Hang. 2Department of Gastroenterology, The First Affiliated Hospital, Zhejiang University School of Medicine Hangzhou China. 3Precision Medicine Center, Taizhou Central Hospital (Taizhou University Hospital) Taizhou China.

Background & Aims: Acute-on-chronic liver failure (ACLF) is a life-threatening syndrome involving dysfunction in multiple immune cells. This study aims to comprehensively profile the dynamic immune responses along the progression of ACLF.

Methods: We conducted single-cell RNA-sequencing (scRNA-seq) of 379,132 individual cells from 45 samples of 32 subjects using peripheral blood mononuclear cells (PBMCs). This included 17 hospitalized hepatitis B virus-related ACLF and early stage non-ACLF patients exhibiting a progressive, stable or recovering course of ACLF. Bulk RNA-Seq, flow cytometry and histological assays were employed in other ACLF cohorts for validation.
Results: The single-cell transcriptome landscape identified forty-one immune cell clusters, including 4 low-density neutrophil clusters, revealing cell-type-specific changes in ACLF progression. We discovered that IL1R2+ macrophage and FCGR4B+ neutrophil are hallmarks of the progressive course of ACLF, especially in the end stage. We also found the intensified interactions of ANNEXIN and VISPATIN signaling within these two cell clusters, showing an anti-inflammation effect in the end stage of ACLF. Uregulation of hypoxia, inflammatory response, TNF a signaling via NFkB in CD24+ neutrophil was observed. Highly activated T cells, including GZMK+CD4+ and GZMK+CD8+ T cells with increased cytotoxic function, gradually decreased in severe ACLF patients. The patients were stratified into six subsets with specific features, significantly associated with ACLF outcome. External validation of cell cluster signatures confirmed their specificity in ACLF progression.

Conclusions: Our comprehensive immune profiling reveals dynamic changes in the innate and adaptive immune responses in progressive ACLF, highlights anti-inflammatory functions of macrophage and provides diverse immune subtypes for ACLF stratified medicine.

Abstract Submission No. 101687

Hypomethylation of TL1A predicts the prognosis of ACHBLF
Xue-fei Wei, Ying Zhang, Tong Zhao, Xue Li, Ji-hui Li, Xing Su, Zhao-hui Wang, Yu-chen Fan, Kai Wang

1Department of Hepatology, Qilu Hospital of Shandong University, Jinan 250012, PR China jinan China, 2Institute of Hepatology, Shandong University, Jinan 250012, PR China Jinan China, 3Shenzhen Research Institute of Shandong University, Shenzhen 518000, PR China Shenzhen China

In Asia, chronic acute hepatitis B liver failure (ACHBLF) accounts for more than 70% of ACLF. ACHBLF has a short- to medium-term mortality rate of about 50-90%. The purpose of this study was to investigate the clinical significance of TL1A and DR3 in development of ACHBLF. In a total of 270 subjects, RT-PCR gate the clinical significance of TL1A and DR3 in development of ACHBLF. In patients with ACHBLF was higher than that in other patients. The results showed that the expression of TL1A and DR3 mRNA in ACHBLF was higher than that in chronic hepatitis patients or healthy control group. In addition, the methylation frequency of TL1A promoter in patients with ACHBLF was significantly lower than that in other groups. Moreover, at the protein level, western blot assay results showed that TL1A expression in patients with ACHBLF was higher than that in other patients. The results indicate that TL1A and its receptor DR3 can predict disease progression in ACHBLF and the methylation of TL1A gene promoter can be used as a useful biomarker for diagnosis of chronic acute hepatitis B failure.

Abstract Submission No. 101691

Hypermethylation of glutathione peroxidase 4 promoter predicts poor prognosis of HBV-ACLF
Xing Su, Ying Zhang, Xuefei Wei, Jieru Yang, Jihui Li, Tong Zhao, Xue Li, Zhao-hui Wang, Yuchen Fan, Kai Wang

1Department of Hepatology, Qilu Hospital of Shandong University Jinan China, 2Hepatology Institute of Shandong University Jinan China

Background: Hepatitis B virus-associated acute-on-chronic liver failure (HBV-ACLF) is a syndrome with a high short-term mortality rate, and its prognosis is critical in clinical management.

Methods: A total of 289 participants including 84 patients with HBV-ACLF, 61 patients with non-HBV ACLF, 94 patients with CHB and 50 HCs were recruited. We detected the expression of GPX4 in peripheral blood mononuclear cells (PBMCs) by real-time quantitative polymerase chain reaction (RT-qPCR). The methylation level of GPX4 gene promoter in PBMCs was detected by TaqMan probe-based quantitative methylation-specific PCR (MethyLight). Receiver operating characteristic (ROC) curves were generated to estimate the discriminations.

Results: The expression levels of GPX4 in PBMCs and serum of HBV-ACLF patients were lower while the methylation level of GPX4 promoter was higher than that of non-HBV-associated acute-on-chronic liver failure (non-HBV ACLF) patients, chronic hepatitis B (CHB) patients and healthy controls (HCs). The methylation level of GPX4 promoter yielded a larger area under the receiver operating characteristic curve (AUROC) than the model for end-stage liver disease (MELD) score in predicting 90-day mortality.

Conclusions: GPX4 promoter methylation level has promising potential as a predictor of 90-day mortality in patients with HBV-ACLF.

Abstract Submission No. 101727

Single-cell landscape of immunological responses in acute-on-chronic hepatitis B liver failure
Yu-Chen Fan, Jing Zuo, Xiao-Lu Zhang, Yu-Xin Tian, Kai Wang

1Department of Hepatology, Qilu Hospital of Shandong University Jinan China, 2Department of Physiology and Pathophysiology, School of Basic Medical Sciences, Cheeloo College of Medicine, Shandong University Jinan China, 3Institute of Hepatology, Shandong University Jinan China

Aim: Acute-on-chronic liver failure (ACLF) is a syndrome that manifests as systemic inflammation and organ failure, which preferentially affects patients with chronic liver disease. In Asia, hepatitis B virus (HBV) is the main etiology. Here we combined the transcriptional profiles of immune cells with assembled T cell receptor (TCR) and B cell receptor (BCR) sequences to suggest dynamic changes in patients with hepatitis B virus-related acute-on-chronic liver failure (HBV-ACLF) and provide a basis for finding immunotherapy targets.

Methods: We performed single-cell RNA sequencing in peripheral blood samples of 3 patients with chronic hepatitis B(CHB) and 8 patients with HBV-ACLF. Single-cell RNA sequencing was used to analyze the functional properties of immune cells. We compared the transcriptional profiles of immune cells and their feature of TCR and BCR between the two groups.

Results: We sequenced a total of 121,096 single cells from two groups. Compared with the patients with CHB, the proportion of NK cells and T cells was significantly downregulated in the patients with HBV-ACLF. In patients with HBV-ACLF, the immune landscape showed immune exhaustion with skewed T cell receptor repertoire and B cell receptor repertoire.

Conclusion: These results suggest the clonal expansion in T cells and B cells of liver failure from chronic HBV infection.
Esophageal varices stratification as early sign of portal hypertension in ACLF: APASL-AARC Study

Cosmas Rinaldi Adithya Lesmana, Sushmita Paney, Neha Sharma, Nupur Sharma, Gaurava Tripathi, Babu Mathew, Manisha Yadav, Vasundhara Bindal, Sadan H. Bhatl, Rakhi Maiwall, Shvetank Sharma, Shiv Kumar Sarin, Jaswinder Singh Maras

1. Mochtar Riyadi Comprehensive Cancer Centre (MRCCC) Siloam Hospital Jakarta Indonesia, 2. Dr Cipto Mangunkusumo National General Hospital Jakarta Indonesia, 3. Medistra Hospital Jakarta Indonesia

Background: Acute on chronic liver failure (ACLF) is a new clinical entity which has a high mortality rate. The presence of esophageal varices (EV) is the hallmark of early sign of PHT in CLD patients. However, study about the presence of EV in ACLF patients is still lacking.

Aim: To know the association of the presence EV and its clinical stratification in ACLF patients.

Method: APASL-ACLF Research Consortium (AARC) database registry was retrospectively reviewed. The data analysis was performed using SPSS version 25.

Results: Of 426 patients, no EV found in 192 patients, whereas small EV was found in 201 patients, and large EV found in 33 patients. Based on ACLF severity grade, small EV was found more in ACLF grade 3 patients (40.8%) when compared to large EV which only found in 18.2%. The presence of high-risk stigmata EV was found to be lower in ACLF grade 3 patients when compared to low-risk EV (17.1% vs. 40.3%). The presence of low-risk EV was more significantly associated with mortality when compared to the presence of high-risk EV (p = 0.032). In ACLF patients, mortality rate was found to be higher in patients without significant PHT when compared to significant PHT (p = 0.000). However, there was no statistically significant in ACLF patients with multi-organ failure (p = 0.100).

Conclusion: The presence of high-risk EV is not really associated with the prognosis of ACLF patients, however, it still needs to be included in the patient’s management to improve the prognosis.

Abstract Submission No. 101948 O-0854

Rifaximin has no beneficial role in ACLF patients admitted to ICU - a double blind RCT

1. Asian Institute of Gastroenterology Hyderabad India, 2. PGIMER Chandigarh India

Background: Patients with acute-on-chronic liver failure (ACLF) often receive antibiotics when admitted to the intensive care unit (ICU). It is unclear if additional rifaximin has any synergistic effect with broad-spectrum antibiotics in ICU patients with acute overt hepatic encephalopathy (OHE).

Methods: In this double-blind trial, APASL-defined ACLF patients admitted to ICU for OHE were randomized to antibiotics alone (ab) or antibiotics with rifaximin (ab+r). HE resolution (or 2-grade reduction), time to resolution, in-hospital mortality, nosocomial infection, and endotoxin level changes were compared.

Results: Of 96 patients with ACLF, 46 received ab alone, and 50 received ab+r. On Kaplan Meier analysis, 41.3% in the antibiotics arm compared to 32% in the antibiotics+rifaximin arm achieved the primary objective (P = 0.34), and the time taken was comparable (P = 0.6). In-hospital mortality was 67.4% in the control arm and 64% in ACLF patients receiving rifaximin (P = 0.98). The proportion of patients achieving infection resolution was comparable (P = 0.71). Nine percent in the ab group and 18% in the ab+r group developed nosocomial infections (P = 0.23). All patients with nosocomial infection died in-hospital. Both groups showed comparable rise in endotoxin levels (P = 0.3).

Conclusion: Rifaximin has no beneficial role in patients with ACLF admitted to ICU.

Abstract Submission No. 101918 O-0854
Ashish Kumar1, Rakhi Maiwall1, - Shalimard2, Shekhar Swaroop3, Faouzi Saliba1, Hlas Konnis1, Praveen Sharma1, Anil K. Arora1, Shivangi Negi1, Shiv K. Sarin1

1Sir Ganga Ram Hospital New Delhi India, 2Institute of Liver and Biliary Sciences (ILBS) New Delhi India, 3All India Institute of Medical Sciences (AIIMS) New Delhi India, 4Hôpital Paul Brousse, Centre Hepato-Biliaire Villejuif France

Background: Alcohol-related acute-on-chronic liver failure (ACLF) is characterized by high mortality rates in the absence of liver transplantation. Plasma exchange (PLEX) has emerged as a potential therapeutic intervention for patients with ACLF of various etiologies. This meta-analysis investigates the short-term and long-term efficacy of PLEX in patients with alcohol-related ACLF compared to standard medical therapy (SMT).

Methods: A comprehensive search was conducted across PubMed, Embase, Scopus, and the Cochrane databases to identify studies comparing PLEX to SMT in patients with alcohol-related ACLF. Pooled odds ratios (OR) with corresponding 95% confidence intervals (CIs) were calculated using the Mantel-Haenszel method within a fixed-effects model. The primary outcome assessed was 30-day survival, with secondary outcomes including 90-day survival.

Results: Our analysis incorporated data from five studies, encompassing 249 patients (119 in the PLEX group vs. 130 in the SMT group). Three studies were retrospective, while two studies were prospective, non-randomized trials. Compared to SMT, PLEX was significantly associated with higher 30-day survival (OR 0.48, 95% CI 0.28-0.84, p = 0.01). However, the pooled odds ratio for 90-day survival with PLEX did not reach statistical significance (OR 0.75, 95% CI 0.44-1.26, p = 0.27). Low heterogeneity was observed between the studies ($I^2 = 24\%$).

Conclusion: PLEX effectively improves short-term survival, as evidenced by a significant improvement in 30-day survival for patients with alcohol-related ACLF. However, its impact on 90-day survival remains inconclusive. Further research, especially randomized controlled trials, is needed to clarify the long-term implications of PLEX in this patient population.

High serum bile acids drive AKI progression and terlipressin non-response in patients with ACLF

Rakhi Maiwall1, Ashini kumar Hidam1, Sherin Thomas1, Shiv Kumar Sarin1

1Department of Hepatology, Institute of Liver and Biliary Sciences New Delhi India

Background and aim: Acute-on-chronic liver failure (ACLF) patients frequently have cholemic nephropathy. The association of serum bile acids(BA) with AKI progression, organ dysfunction, and mortality has not been studied.

Methods: In a prospective cohort of ACLF patients (n=242) with AKI, serum BA and urine neutrophil-gelatinase-associated lipocalin (NGAL) were measured at enrolment. Logistic regression was performed to identify predictors of AKI progression.

Results: ACLF patients, aged 43.2 ± 9.8 years, 91.2% males, 73% with alcohol etiology, 87% with sepsis, AKI stages (1:2:3) 40%:31%:29%, 61% with HRS-AKI, the mean serum BAs were 154.2±45.8 mg/dl, and NGAL of 1881±1714 ng/ml. AKI progression at day 4 was observed in 42.6%, 26% required dialysis and 48% died at 28 days. On multivariable analysis, higher BA (OR 1.008,1.001-1.016), AARC score (OR 1.72,1.37-2.15), NGAL (OR 1.56,1.01-2.46), and number of organ failures (OR 1.89,1.27-2.83) predicted AKI progression which was an independent predictor of 28-day mortality (HR 1.98,1.25-3.16). The BA correlated with circulatory failure (OR 1.008, 1.001-1.015) but not with brain and pulmonary failure(p>0.05).

Conclusion: Serum BA correlates with circulatory failure, and predicts AKI progression and non-response in HRS-AKI but not mortality. High serum BA (>175 mg/dl), NGAL, and the presence of bile casts could signify structural AKI and limited response to vasoconstrictors. AKI progression determines worse clinical outcomes therefore therapeutic modalities targeting reduction of BA may improve outcomes in ACLF patients with AKI.

Second hit acute insult increases mortality in patients of Acute-On-Chronic Liver Failure

ASHOK CHOUDHURY1, VINOD ARORA1, SHIV KUMAR SARIN1, AARC CONSORTIUM1,2

Background: Acute-on-chronic liver failure (ACLF) is characterized by rapid deterioration of liver function, while cirrhosis is a slowly progressive disease. Liver transplantation (LT) remains the treatment of choice for these patients with advanced disease. There are no studies evaluating the health-related quality of life (HRQoL) of patients with APASL-defined ACLF, which we aimed to assess.

Methods: In this cross-sectional study, consecutive patients with ACLF and decompensated cirrhosis attending the AIG Hospitals, Hyderabad, were included and assessed for SF-36 HRQoL scoring. The primary outcome was HRQoL among patients with decompensated cirrhosis and ACLF after matching for age and severity scores.

Results: A total of 350 patients were included in the study. Thirty-two percent (n=113) were ACLF, and 68% (n=237) were cirrhosis. On propensity-matched analysis (matched for age and MELD Na score), 102 patients with ACLF were matched with 35 patients with cirrhosis. Cumulative score of general health was lower in both groups (41.45%±16.4% vs. 44.3%±17.45%; P=0.4). Both groups performed poorly on energy levels scale (49.3% vs. 53%; P=0.41). On other scales, including emotional (70% vs. 72%), social (68.24% vs. 73%), and pain (84.37% vs. 85.22%), were adequate in both groups. Interestingly, despite matching, the physical functioning of patients with cirrhosis (46.31%±27.2%) was much lower than those with ACLF (60%±24.7%; P=0.007). Transplant-free survival was 19% (19/101) among patients with ACLF compared to 14.3% (5/35) at day 30 (P=0.54).

Conclusions: Patients with decompensated cirrhosis have worse physical functioning than patients with ACLF. Further research aimed at interventions to improve the QoL is required.
LPCAT3/LPLAT12 deficiency in the liver ameliorates acetaminophen-induced acute liver injury.

Natsuko Inagaki1, Hiroki Nakanishi3, Takayo Ohto3, Hideo Japan, 4Institute of Microbial Chemistry Tokyo Japan

Background and Aims: ACLF is due to underlying chronic liver disease with super-added acute hepatic insult leading to high short term mortality. We analysed the impact of second hit acute insult to a primary chronic liver disease (CLD) presenting as ACLF.

Patients and Methods: We analyzed the prospectively collected data from AARC registry. Clinical data, laboratory parameters, complications and survival were serially noted. Acute insult is considered second hit if its of different i.e. ACLF in ethanol related or HBV related CLD in absence of alcoholic hepatitis or HBV reactivation.

Results: Total of 8684 patients [mean age 44.6 ±11.6 years, 86.2% male] with alcohol (5684,65%) followed by HBV (1621, 18.7%), AILD (787,9.1%), Cryptogenic/NASH (407,4.7%), and HCV (177,2%). Similarly the acute insult in majority was SAH (4933, 56.8%), HBV reactivation (1069,12.3%), DILI (475,5.5%) followed by AVH(462, 5.3%). The alcohol CLD presented with ACLF due to SAH in 66.2% cases, whereas as AVH (4.6%) and DILI(5.3%) accounted for nearly one third. Similarly in patients with HBV CLD, the HBV reactivation was seen only in 26.4%, but the majority were due to alcoholic hepatitis (45.1%), AVH(6.5%), DILI (5.9%) and others in rest. Interestingly the second hit i.e another insult was seen in 50.2% (4398) cases. The single hit i.e ALD with SAH or HBV reactivation in HBV CLD or AIH flare associated with a better younger age, lower bilirubin, albumin, INR, AARC score, less organ failure, lower incidence of HE, sepsis, variceal bleed, need of RRT, ICU care and ventilatory support than those having another second hit etiology (p<0.001). A higher 90 days mortality [53.9% versus 46.4%,OR=1.37(95CI 1.15-1.67), p<0.001] with shorter median survival [48.1 days versus 54.8 days, p=0.001] noted with second hit acute insult.

Conclusion: In this large cohort, the ACLF cohort had a different acute insult than the primary chronic liver disease in nearly half of the cases. This innovative concept of second hit leading to ACLF had a different natural course and is associated with a poor outcome. A search for the acute insult and consideration of necessary definitive therapy, may guide the mangement decision to improve outcome.

Abstract Submission No. 200144  O-0860

LPCAT3/LPLAT12 deficiency in the liver ameliorates acetaminophen-induced acute liver injury.

Natsuko Inagaki2, Hiroki Nakanishi3, Takayo Ohto3, Hideo Shindou2, Takao Shimizu6

1The University of Tokyo Tokyo Japan, 2National Center for Global Health and Medicine Tokyo Japan, 3Lipidome Lab. Co. LTD Akita Japan, 4Institute of Microbial Chemistry Tokyo Japan

Acetaminophen (APAP) is a double-edged sword, mainly depending on the dosage. A moderate dose of APAP is effective for fever and pain relief; however, an overdose induces acute liver injury. The mechanism underlying APAP-induced acute liver failure is unclear, and its treatment is limited. A recent report has shown that several oxidized phospholipids are associated with APAP-induced acute liver failure. Lyso-phosphatidylcholine acyltransferase 3 (Lpcat3, Lplat12), which is highly expressed in the liver, preferentially catalyzes the incorporation of arachidonate into lysophospholipids (PLs). In the present study, we investigated the roles of Lpcat3 on APAP-induced acute liver injury using liver-specific Lpcat3-knockout mice. Hepatic Lpcat3 deficiency reduced the degree of APAP-induced necrosis of hepatocytes around zone 3 and ameliorated the elevation of hepatic injury serum marker levels, and prolonged survival. Lipidomic analysis showed that the accumulation of oxidized and hydroperoxidized phospholipids was suppressed in Lpcat3-knockout mice. The amelioration of APAP-induced acute liver injury was due not only to the reduction in the lipid synthesis of arachidonic acid PLs because of Lpcat3 deficiency, but also to the promotion of the APAP detoxification pathway by facilitating the conjugation of glutathione and N-acetyl-p-benzoquinone imine. Our findings suggest that Lpcat3 is a potential therapeutic target for treating APAP-induced acute liver injury.

Abstract Submission No. 100086  O-0861

Noninvasive proteomic biomarkers for HEV-related acute liver failure

Jian Wu1, Honggui Cao2

1Department of Clinical Laboratory, The Affiliated Suzhou Hospital of Nanjing Medical University, Suzhou Municipal Hospital, Gusu School, Nanjing Medical University, 242 Guangji Road, Suzhou 215008, Jiangsu, China; Suzhou China, 2State Key Laboratory for Diagnosis and Treatment of Infectious Diseases, National Clinical Research Center for Infectious Diseases, The First Affiliated Hospital, Zhejiang University School of Medicine, 79 Qingchun Rd, Hangzhou City, Zhejiang Province, 31

Background: Timely and effective prognostic biomarkers for hepatitis E virus (HEV)-related acute liver failure (ALF) are urgently needed.

Methods We performed four tandem mass tag (TMT)-labeled quantitative proteomic and targeted proteomics parallel reaction monitoring (PRM) studies on cross-sectional cohort 1 and 2 including 20 acute hepatitis E and 20 HEV-ALF patients respectively.

Results: Pregnancy zone protein (PZP) is a potential prognostic biomarker for HEV-ALF. PZP was identified by TMT and PRM quantitative proteomics. In the derivation cohort, PZP levels of the HEV-ALF patients in survival group were significantly higher than those of the dead group. According to the median level of PZP, HEV-ALF patients in the retrospective cohort 1 were divided into the high PZP (>1316.18 ng/L) and low PZP (≤1316.18 ng/L) groups. The survival time of the high PZP group was significantly longer than that of the low PZP group. Compared with PZP levels at admission, levels at discharge increased significantly in the improvement group, and decreased significantly in both the fluctuation and deterioration groups. Besides, multivariate logistic regression showed that laminin, hepatic encephalopathy, TBI, and PZP were independent factors affecting the prognosis of HEV-ALF patients, which were used to establish a novel prognostic model (ePLT). The assessment in the derivation and validation cohorts showed that the ePLT score was significantly superior to the MELD, KCH and Child-Pugh scores.

Conclusions: PZP is a promising prognostic biomarker, and ePLT is a high-performance prognostic score for HEV-ALF patients, which contribute to clinical decision-making in the management of HEV-ALF.

Prospective study of the effect of TPO on platelets and prognosis in patients with ACLF

Jing Liang¹, Gang Liu², Fei Tang³, fenghui li², fushuang ha¹

¹Tianjin Third Central Hospital Tianjin China; ²Tianjin Dongli Hospital Tianjin China

**Objective:** To evaluate the dynamic changes in platelet and liver function in ACLF patients complicated with severe thrombocytopenia with recombinant human thrombopoietin (rhTPO) in a prospective cohort to observe the effects of elevated platelets on bleeding events and 90-day mortality in patients with ACLF.

**Methods:** Seventy patients with ACLF complicated with severe thrombocytopenia were prospectively enrolled and divided into a TPO group and a control group, with 35 patients in each group. The TPO group was given rhTPO for 7 days. The baseline, 7-day and 14-day PLT counts and liver function indices were compared and 90-day mortality and incidence of bleeding events were observed.

**Results:** There was no significant difference in 90-day mortality between the TPO group and the control group (8.6% vs. 17.1%, P=0.284). The incidence of bleeding events within 90 days was 11.4% in the TPO group and 22.9% in the control group (P=0.205). The PLT count in the TPO group was significantly higher than that at baseline and 7 and 14 days after treatment (28.10^10/L vs. 64.10^10/L vs. 73.10^10/L, P=0.001), and the PLT count peaked at 14 days. The serum HGF and TPO levels were significantly higher than those at baseline (serum HGF: 130.4 pg/ml vs. 195.4 pg/ml, P=0.000) and (serum TPO: 41.8 pg/ml vs. 143.7 pg/ml, P=0.000) in the TPO group at 7 days after treatment. The serum albumin level, INR and MELD score in the TPO group at 14 days after treatment were significantly improved compared with those before treatment (ALB 34.5 g/L vs. 28.2 g/L, P<0.05; INR 1.6 vs. 1.7, P<0.05; MELD 14.7 vs. 16.0, P<0.05).

**Conclusion:** rhTPO can significantly increase the PLT count in ACLF patients with thrombocytopenia, reduce the occurrence of bleeding events, and promote the improvement of liver function, and it has no significant effect on 90-day mortality.

Abstract Submission No. 100573

A case report of hepatic amyloidosis presenting as Acute-on-Chronic Liver Failure

Thanh Huu Nguyen¹, Anh Duc Duong², Tung Lam Nguyen³

¹College of Health Sciences, VinUniversity Ha Noi Vietnam; ²Department of Gastroenterology, 108 Central Military Hospital Ha Noi Vietnam

Amyloidosis encompasses a heterogeneity of disorders characterized by the extracellular deposition of abnormal fibrillar proteins, which frequently involves the liver but hepatic failure rarely occurs. Herein, we present a case of a 54-year-old female with no significant liver history, use of unknown herbal medicine 3 months prior, presented with progressive jaundice for 2 months, abdominal distension for 6 weeks, associated with hepatosplenomegaly, ascites, and stable hemodynamics. The initial laboratory findings showed serum alanine aminotransferase of 24 IU/L, serum aspartate aminotransferase of 127 IU/L, total bilirubin of 12.26 mg/dL, INR of 1.55 with negative viral hepatitis, autoimmune profiles and no significant findings on abdominal computed tomography. A transjugular liver biopsy was performed and revealed extensive deposition of extracellular hyaline material, which is not typical for sinusoidal obstruction syndrome caused by alkaloid toxicity. The patient’s condition deteriorated rapidly and was managed symptomatically with a transjugular intrahepatic portosystemic shunt, however, the patient passed away one month later before making a definitive diagnosis. The patient’s liver biopsy result was sent to the abroad center and showed Salmon-pink color material with birefringence under polarized light on Congo Red stain, which indicates amyloidosis. The diagnostic challenge in this case occurred in the etiological work-up for progressive jaundice and acute on chronic liver failure. We urge clinicians not to be satisfied with a diagnosis that could not explain fully the lab results and to have high clinical suspicion to make an early diagnosis and initiate prompt treatment, particularly in limited-resourced countries.

Abstract Submission No. 100723

**O-0865**

Investigating factors involved in the rate of the examination success of transjugular liver biopsy.

Naohiro Wada¹, Asako Nogami¹, Tomohiro Ootani¹, Michihiro Iwaki¹, Takashi Kobayashi¹, Masato Yoneda¹, Satoru Saitou², Atushi Nakajima¹

¹Yokohama City University Yokohama Japan; ²Sanno hospital Tokyo Japan

**Background:** Performing percutaneous liver biopsies could be impossible or difficult in patients with ascites or coagulation abnormality. Transjugular liver biopsy (TJLB) is a relatively safe alternative technique in such cases. There are limited studies on the factors involved in its technical success of TJLB. This study aimed to investigate the factors that influence the technical success of TJLB.

**Methods:** We enrolled fifty patients who underwent TJLB at our hospital between August 2020 and April 2023. We retrospectively measured the angle between the inferior vena cava (IVC) and the hepatic vein (HV) using CT or MRI coronal sections. In cases where TJLB was successful, we measured the angle between the IVC and the HV at the biopsy site. In cases where TJLB was unsuccessful, we measured the angle between the IVC and the right hepatic vein (RHV).

**Results:** TJLB was successfully performed in 42 cases (84.0%). Among these successful TJLB procedures, 38 cases (90.5%) were
performed on the RHV, and 4 cases (9.5%) on the middle hepatic vein (MHV). We were able to measure the angles between the IVC and the HV in 31 cases. The mean angles between the IVC and the HV in the successful (n=24) and unsuccessful (n=7) groups were 46.7±10.0° and 59.9±13.6°, respectively, and were significantly smaller in the successful group (p=0.042).

Conclusion: We are more likely to perfuse TJLB successfully in cases in which the angle between the IVC and the HV is small.

Association of Coexistent HBsAg and anti-HBs with Prognosis of HBV-ACLF Patients

Jian Li1,2, Xiaonan Wu1, Siyi Liu2, Qijian Zang3, Chengbin Zhu2, Yingren Zhao1,2,3, Yingli He4
1Department of Infectious Diseases, First Affiliated Teaching Hospital, School of Medicine, Xi’an Jiaotong University, Xi’an, Shaanxi, China; 2Institute of Hepatology, First Affiliated Teaching Hospital, School of Medicine, Xi’an Jiaotong University Xi’an China; 3Shaanxi Clinical Research Center of Infectious Diseases Xi’an China

Objectives: Coexistence of hepatitis B surface antigen (HBsAg) and antibody against HBsAg (anti-HBs) constitutes an atypical serological profile in chronic hepatitis B infection. The characteristics and impact of this serological pattern in the critically ill population of HBV-ACLF remain unclear.

Methods: Clinical data from 561 HBV-related ACLF patients were retrospectively collected. Flow cytometry was used to detect the peripheral blood lymphocyte subsets. The outcome was recorded as surviving or non-surviving in a 90-day follow-up.

Results: Among 561 HBV-ACLF patients, 31 cases exhibited the double-positive pattern for HBsAg and anti-HBs, resulting in a coexistence rate of 5.5%. Compared with patients without anti-HBs, those with anti-HBs had higher HBV DNA levels (4.9 [2.8-5.4 log10] IU/mL vs. 4.5 [3.4-5.6 log10] IU/mL, p = 0.017) and serum core antibody titers but lower HBsAg levels (47.5 [7.6-169.3] IU/mL vs. 163.2 [30.2-1601.2] IU/mL, p = 0.034). Patients with the coexistence of HBsAg and anti-HBs were older (50.0 [30.0-73.25] vs 42.0 [33.0-51.0] years, p = 0.034), had a higher proportion of cirrhosis (87.1% vs 69.6%, p = 0.038), and higher total bilirubin levels (329.2 [213.3-456.8] U/L vs. 280.0 [180.6-393.4] U/L, p = 0.022). Lymphocyte subset analysis suggested that peripheral CD3+, CD4+, and CD8+ T-cell counts were lower in HBsAg and anti-HBs coexisting patients. Survival analysis indicated poorer short-term prognosis for patients with anti-HBs, with a significantly higher mortality rate compared to those without anti-HBs (58.1% vs. 38.9%, p = 0.034).

Conclusion: Coexistence of HBsAg and anti-HBs may be associated with a more severe disease state in HBV-ACLF.

Long-term prognosis of HBV-ACLF patients with extremely low-level viremia

Qiao Zhang1,2, Xiaonan Wu1, Yamin Wang1, Qiannan Wang1, Pan Huang1, Xiaoli Zhang1, Danfeng Ren1, Taotao Yan1,2, Yingren Zhao3, Yingli He4

1Hepatology Unit, Department of Infectious Diseases & Clinical Research Center for Infectious Diseases, the First Affiliated Hospital of Xi’an Jiaotong University, Xi’an, Shaanxi, China. Xi’an China, 2National Regional Infectious Diseases Center Co-constructed by National Health Commission of PRC and People’s Government of Shaanxi Province & Shaanxi Clinical Medical Research Center of Infectious Diseases, Xi’an, Shaanxi, China. Xi’an China

Background: High viral load is closely associated with outcomes of chronic hepatitis B. However, for patients with viral loads lower than the limit of quantification (LLOQ), especially those who have survived liver failure, the long-term outcomes remain unclear.

Methods: 80 HBV-ACLF patients who survived more than 48 weeks without liver transplantation and received NUCs therapy were enrolled. Based on HBV-DNA loads after 48 weeks treatment, patients were categorized into the UD (undetectable), extremely low-level viremia (eLLV, detectable but LLOQ) group, and partial virological response (PVR, ≥ 2000IU/mL) groups.

Results: 1. 80 HBV-ACLF patients were followed for 228.09±97.01 weeks, with most in the eLLV group (n=43, 53.75%), followed by LLV (n=25, 31.25%), UD (n=10, 12.5%), and PVR (n=2, 2.5%) group.
2. In the eLLV group, HBsAg levels were significantly higher than UD group (1804.66 [325.67, 3130.58] vs 35.17 [0.00, 989.79] IU/mL, P=0.004), while anti-HBs levels were significantly lower (0.15 [0, 0.57] vs. 98.96 [3.40, 276.05] mIU/mL, P=0.003). Additionally, eLLV group exhibited significantly higher anti-HBe levels compared to the UD group (0.84 [0.16, 1.52] vs 1.60 [1.00, 2.28] S/CO, P=0.042, Table1).
3. Kaplan-Meier survival analysis indicated superior overall survival in the eLLV group compared to the LLV group (P=0.029, Figure 1).
4. Moreover, eLLV group had lower cumulative incidences of recurrent decompensation events than the LLV group (P=0.013, Figure 2).

Conclusions: HBV-ACLF patients with eLLV demonstrated superior long-term outcomes compared to the LLV group. Adjusting antiviral regimens for LLV patients to achieve eLLV levels may enhance long-term prognosis.

Diabetes Mellitus Linked to Higher Mortality in Alcohol-related Acute-on-Chronic Liver Failure

Ashish Kumar1, Shiv K. Sarin2, Ashok Choudhury3, Vinod Arora4, Anil Arora1, Praveen Sharma1, Mohammad Rela3, Dinesh Jothimani3, Mamun A. Mahtab4, Harshad Devarbhavi5, C. E. Eapen6, Ashish Goel7, Cesar Yaghhi8, Q Ning9, APASL ACLF Research Consortium (AARC) APASL ACLF working Party2

1Sir Ganga Ram Hospital New Delhi India, 2Institute of Liver and Biliary Sciences (ILBS) New Delhi India, 3DR. Rela Institute Chennai India, 4Bangabandhu Sheikh Mujib Medical University Dhaka Bangladesh, 5St. John’s Medical College Bengaluru India, 6CMC Vellore Vellore India, 7Saint Joseph University Beirut Lebanon, 8Tongji Hospital Wuhan China

Background: Acute-on-Chronic Liver Failure (ACLF) is characterized by acute deterioration in patients with chronic liver disease, leading to multiple organ failures and a high mortality. Alcohol is the most common cause of ACLF. While diabetes mellitus is a risk factor for adverse outcomes in liver disease, its specific impact on outcomes in alcohol-related ACLF remains elusive.

Aims: This study aims to assess the impact of diabetes mellitus on the mortality of patients with alcohol-related ACLF.

Methods: We recruited patients with alcohol-related ACLF from the AARC registry. The diagnosis of alcohol-related ACLF was established when the treating unit identified alcohol as both the etiology of
chronic liver disease (CLD) and the acute precipitant. Patients with coexisting other etiologies of CLD or other precipitants (such as HBV, HCV, HEV, DILI etc.) were excluded. Patients were categorized based on the presence or absence of diabetes. The primary outcome was 90-day mortality, with the analysis considering only baseline clinical, laboratory features, and severity scores.

**Results:** The study included a total of 2,096 patients with alcohol-related ACLF, comprising 109 diabetic (91.7% male, median age 45 years) and 1,987 non-diabetic individuals (90.9% male, median age 42 years). The median MELD-Na score was 31.0 (IQR 27.0-36.0) while the median CTP score was 12 (IQR 11.0-12.0) for both groups. By 90 days, 979 (47%) patients had died, and 109 (5%) patients had received liver transplantation (LT); 12 patients died even after LT. The 90-day mortality was significantly higher in diabetics compared to non-diabetics (67.9% vs 45.5%, p<0.05). A log-rank test demonstrated a statistically significant difference in survival between patients with and without diabetes mellitus in both overall survival (p<0.01) and transplant-free survival analyses (p<0.01), indicating a substantial impact of diabetes on outcomes in alcohol-related ACLF (Figure).

**Conclusions:** The presence of diabetes mellitus in patients with alcohol-related ACLF markedly increases the risk of mortality, highlighting the particularly dangerous nature of this condition in diabetic individuals. This underscores the urgency for further research to elucidate the underlying mechanisms of this association.

**Antibiotics and steroids for 4-weeks in ACLF-AH with steroid response showed reduction of infections**

Vinod Arora1, Ashok Choudhury1, Mohd. Rela2, Mamun Al Mahtab1, Akash Shukla4, Hasnik Ghazinyan5, Sanjeev Sachdeva6, S S Hamid1, Anand Kulkarni7, Soek Siam Tan8, Dong Joon Kim9, P N Rao9, Amna Subhan Butt7, Wasim Jafri9, Shiv Kumar Sarin1

1Department of Hepatology, ILBS Hospital Delhi India, 2Dr. Rela Institute Chennai India, 3Department of Hepatology, Bangabandhu Sheikh Mujib Medical University Dhaka Bangladesh, 4Department of Gastroenterology, Lokmanya Tilak Municipal General Hospital and Lokmanya Tilak Municipal Medical College, (LTMMC) Mumbai India, 5Department of Hepatology, Nork Clinical Hospital of Infectious Disease, Yerevan Armenia, 6G.B. Pant Hospital New Delhi India, 7Department of Medicine, Aga Khan University Hospital Karachi Pakistan, 8Asian Institute of Gastroenterology Hyderabad India, 9Department of Medicine, Hospital Selayang, Bata Caves, Selangor Malaysia, 10Hallym University Medical Centre Chuncheon Republic of Korea

**Introduction:** In this retrospective analysis we analysed whether oral antibiotics (cefixime) at discharge given for 1-week vs. 4-weeks in combination with steroids reduced infections in ACLF (alcoholic hepatitis).

**Patient and methods:** Retrospective database of APASL-AARC consortium was taken from April 2021-April 2022 and prospectively data was followed up for 6-months with patients of ACLF and having alcoholic hepatitis (steroid eligible) and received steroids for 28 days. Primary objective was to study infections at day 28. Secondary objectives were to study mortality at 28-day and 90 days; incidence of HRS; HE; AKI.

**Results:** 1124 patients with ACLF collected during the period, 534 patients (47.5%) having alcoholic hepatitis were screened; 110 (20.59%) patients had received steroids (prednisolone 40mg for 4 weeks) of which 28 patients (25.4%) received oral cefixime 200mg/Bid for 4 weeks while 82 patients (74.5%) received oral cefixime (200mg/Bid 7 days) along steroids. Incidence of AKI {6/28 (21.42%) vs. 19/82 (23.17%), P=1.00}; UGIB {2/28 (7.1%) vs. 9/82 (10.9%), P=0.72} were comparable. Incidence of infections at 28 days {5/28 (17.8%) vs. 35/82 (42.6%), P=0.02}, repeated hospitalizations {3/28 (10.7%) vs. 26/82 (31.7%), P=0.04}, mean number of hospitalized days (90-days) {10± 3.4 vs 18 ± 6.7, P=0.001} was lower in the 4-week arm. Incidence of pneumonia {7.1% (2/28) vs. 21.9% (18/82), P=0.09}; cellulitis {10.7% (3/28) vs. 14.6% (12/82), P=0.75}; SBP {7.1% (2/28) vs. 23.1% (19/82), P=0.09} was lower in the 4-week arm, not significant. Of steroid non responders {30/82 (36.5%)}; 13/30 were continued on antibiotics suspecting subclinical infection showed lower infection rate requiring hospitalization {12/13 (15.3%) vs. 9/17 (52.9%), P=0.04}; Lower 28-day mortality was also noted in 4-week arm {2/28 (7.1%) vs. 18/82 (21.9%), P=0.09}.

**Conclusions:** 4-week antibiotic-steroid therapy in steroid responder AH helped in reduction of severity of infections; duration of hospitalization; improved 4-week mortality.

**EXPERIENCE ON USE OF DPMAS AMONG PATIENTS WITH ACLF AND DECOMPENSATED LIVER CIRRHOSIS - CASE SERIES**

Jose Orlando Nicolas1, Mara Teresa Panlilio2, Ira I Yu3

1National Kidney and Transplant Institute Quezon City Philippines, 2National Kidney and Transplant Institute Quezon City Philippines, 3National Kidney and Transplant Institute Quezon City Bulacan

Liver transplantation is the definitive management for acute liver (ALF) and end-stage liver disease (ESLD). This is limited by accessibility, lack of potential donors, and cost. At present, as a bridge for liver transplantation, artificial liver support systems (ALSS) such as double plasma molecular adsorption system (DPMAS) are being utilized.

This case series aimed to review outcomes of patients who had DPMAS from 2018 to 2023. This case series included patients from a tertiary referral center in the Philippines. Records of patients who had liver cirrhosis who underwent DPMAS were reviewed.

Six patients were included in this series. Four out of the six patients were discharged after DPMAS, while two died from multi-organ failure. Prothrombin time and INR improved post-DPMAS. Consequently, prognostic scores, specifically MELD-Na, was lower. Likewise, Hepatic Encephalopathy (HE) grade and degree of ascites improved. Two of these patients underwent successful liver transplantation eventually. Patients who underwent DPMAS in this series showed improvement in laboratory parameters measuring hepatic synthetic function, and MELD-Na. DPMAS is a promising modality for bridging ALF and end-stage liver disease to transplantation, and in some cases, recovery to compensated state.

**Asces in Hepatitis A-induced liver failure: Does it impact outcome?**

Moinak Sen Sarma1, Ujjal Poddar2, Anshu Srivastava1, Surender Kumar Yachha1

1Dept of Pediatric Gastroenterology, Sanjay Gandhi Postgraduate Institute of Medical Sciences Lucknow India
Introduction: Hepatitis A virus (HAV) in developing nations is one of the leading causes of acute liver failure (ALF) in children. Survival with native liver (SNL) is guarded. We aimed to study the factors that are associated with outcome in this condition.

Methods: A prospectively maintained database registered all ALF admitted between 2017-2022. Poor outcome (PO) was defined as death or requirement of liver transplantation. Underlying chronic liver disease was excluded.

Results: Comparison of HAV-ALF (n=55) vs non-HAV-ALF (n=44) [hepatitis B (n=12), hepatitis E (n=2), EBstein-Barr (n=7), parvovirus (n=6) and indeterminate (n=19)] showed age (7±4.0y vs. 9.9 ±4.6y, p=0.002), duration of illness (33.9±23.8 vs 21±6.8 days, p=0.04), PELD score (31.4±14.1 vs 27.4±20.1, p=0.07) and SNL (51% vs 38%, p=0.1). Among HAV-ALF, 61% had ascites (35% at presentation, 26% during admission; jaundice to ascites duration 17±22 days) and 65% had encephalopathy (55% at presentation, 10% during admission; jaundice to encephalopathy duration 15.5±19 days). PO was seen in 90% of those who developed ascites prior to encephalopathy (41%) and required large volume paracentesis (33%). Violin plots (Figure 1) shows comparison of liver function with final outcome. On multiple step-wise logistic regression, ascites preceding encephalopathy [OR 2.1 [(1.6-3.3), p=0.002], spontaneous bacterial peritonitis [OR 1.8[(1.2-2.3), p=0.02] and PELD score [OR 4.3[(2.3-4.8), p=0.001] were independent predictors of PO. At presentation, PELD score cutoff <23.5 (AUROC 0.86) and serum albumin >3.1 g/dL (AUROC 0.77) were associated with SNL.

Conclusions: Ascites preceding encephalopathy and spontaneous bacterial peritonitis are associated with poor outcomes in acute liver failure. Universal vaccination policies need to be reinforced.

Abstract Submission No. 101442

Recent trend of acute hepatitis and acute liver failure in our hospital

Masazumi Onuki1, Jun Inoue1, Masashi Ninomiya1, Akitoshi Sano1, Mio Tsuruoka1, Kosuke Sato1, Satoko Sawahashi2, Keishi Ouchi1, Kotaro Doi1, Atsushi Masamune1

1Division of Gastroenterology, Tohoku University Graduate School of Medicine Sendai Japan

Background and Aim: The etiologies of acute hepatitis (AH) and acute liver failure (ALF) are various. This study aimed to clarify recent trends and the prognosis for each cause.

Methods: Patients with AH and ALF admitted to our department from January 2001 to October 2023 were included. Patients were classified as having ALF if PT fell below 40% within 8 weeks of onset.

Results: There were 238 eligible patients (100 males and 138 females) with a median age of 45 years; the highest T-bil, AST, and ALT (median) were 7.8 mg/dl, 770 U/L, and 1128 U/L, respectively, and the lowest PT was 64.1%. The number of cases averaged 8.6 cases/year in 2015-2021, but increased to 14 cases/year after 2022. As for the etiologies, unknown, HBV, and drug-related were the most common, at 25/20/21%, respectively. HBV showed a decreasing trend, while an increasing trend in unknown and drug-related. Cases with COVID-19 infection were included among the unknown causes since 2021. The proportion of women increased significantly from 58/124 (47%) in 2001-2011 to 80/114 (70%) in 2012-2023. ALF occurred in 73 patients (30.7%) overall. Unknown/HBV was the most common causes of ALF. The prognosis for unknown and HBV was poor, with liver transplantation/death rates of 79% and 71%, respectively. Among comatose ALF patients with and without transplantation, 2/12(17%) and 28/30(93%) died, respectively.

Conclusions: Recently, HBV-related AH and ALF have decreased, while unknown and drug-related cases tended to increase. The overall number of cases also showed an increasing trend, as for the proportion of women.

Isoproterenol attenuates LPS/D-GalN-induced liver injury through β-arrestin2 exerts anti-inflammatory

tianzhi Ni1, shan Fu1, yalei Zhao1, xiaoli Zhang1, ruojing Wang1, danfeng Ren1, juan Li1, yali Feng1, yuany Yang1, yingli He1, yingren Zhao1, jinfeng Liu1

1Department of Infectious Diseases and Hepatopathy, The First Affiliated Hospital of Xi’an Jiaotong University, China x’an China

Background and Aims: Previous studies have shown that stimulating B2-adrenergic receptors inhibits lipopolysaccharide (LPS)-induced macrophage production of inflammatory factors. The aim of the study was to explore the mechanisms by which the SNS alleviates liver inflammatory harm during acute liver failure (ALF).

Methods: C57BL/6J mice were administered isoproterenol (ISO) in an ALF model established using LPS and D-galactosamine (D-GaIN). THP-1 cells were pretreated with ISO before LPS administration. β-arrestin2 expression in THP-1 cells was knocked down by siRNAs in vitro.

Results: In LPS/D-GaIN-induced ALF mice, ISO administration led to a decrease in serum levels of proinflammatory cytokines (TNF-α, IL-1β, and IL-6), mitigating liver damage and reducing the mortality of mice. Furthermore, ISO reduced the infiltration of M1-type macrophages in the liver of ALF mice. Proteomic enrichment analysis suggested that ISO mainly affected the function of liver macrophages, especially the inflammation signaling, such as the MAPK and NF-κB pathways. Pretreatment with ISO resulted in a reduction of LPS-stimulated inflammatory factors (TNF-α, IL-1β, and IL-6) in THP-1 cells. Additionally, ISO treatment attenuated the phosphorylation levels of MAPK P38 and NF-κB P65 by LPS in activated macrophages. Subsequently, β-arrestin2 was knocked down in THP-1 cells. Interestingly, the in vitro results showed that the deficiency of β-arrestin2 dramatically reversed anti-inflammation of adrenergic and inhibited the phosphorylation activity of NF-κB and MAPK signals.

Conclusion: Pretreatment with ISO could potentially exert anti-inflammatory effects through β-arrestin2 and may serve as an innovative pharmacotherapy for the purpose of delaying the pathogenesis and progression of ALF.

Cost-effectiveness analysis of two non-biological artificial liver modes in early HBV-ACLF

Jia Chen1, Zhexuan Deng1, Qiumin Luo1, Wenxiong Xu1,2, Liang Peng3

1Department of Infectious Diseases, Third Affiliated Hospital of Sun Yat-sen University Guangzhou China, 2Guangdong Key Laboratory of Liver Disease Research, The Third Affiliated Hospital of Sun Yat-sen University Guangzhou China, 3Key Laboratory of Tropical Disease Control, Ministry of Education, Sun Yat-sen University Guangzhou China
Objective: This study aimed to evaluate the cost-effectiveness of two artificial liver support systems, double plasma molecular adsorption system with sequential low-dose plasma exchange (DPMAS+LPE) and plasma exchange (PE), in early hepatitis B virus-related acute-on-chronic liver failure (HBV-ACLF).

Methods: 95 patients treated with DPMAS+LPE and 95 with PE at the Third Affiliated Hospital of Sun Yat-sen University were retrospectively analyzed with a 90-day follow-up. Cost-effectiveness analysis of 90-day survival rates and direct medical costs from the healthcare system perspective was conducted, incorporating probabilistic sensitivity analysis.

Results: The average total costs over 90 days were ¥91,661 [95%CI: 85,284 - 99,879] for DPMAS+LPE and ¥86,853 [95%CI: 78,001 - 98,822] for PE, with mean survival rates of 91.59% [95%CI: 82.21% - 94.74%] and 83.12% [95%CI: 73.68% - 89.47%], respectively. Cost-effectiveness ratios were ¥100,078 and ¥104,491 for the two groups. The incremental cost-effectiveness ratio of DPMAS+LPE versus PE was ¥56,765, below China’s per capita GDP in 2022. Probabilistic sensitivity analysis indicated an 85% probability of DPMAS+LPE being economically favorable compared to PE when the willingness-to-pay threshold was set at 3 times the per capita GDP.

Conclusion: DPMAS+LPE treatment improves the 90-day survival rate in early HBV-ACLF patients. Despite increased direct medical costs, the additional cost required per incremental survival rate is deemed acceptable, suggesting the economic viability of DPMAS+LPE therapy.
vivo treatment experiments were conducted to probe the potential synthesis of VISTA in shaping the iCCA tumor microenvironment. Expression levels were utilized to construct patient stratification and prognosis. VISTA abundance and distribution within iCCA were assessed as a strategy to augment the efficacy of anti-PD-1/CTLA-4 therapy in challenging disease.

Conclusions: Targeting the myeloid checkpoint VISTA holds promise between VISTA and the immunosuppressive phenotype of myeloid cells. Ex vivo treatment experiments suggested that VISTA blockade mitigated immune exhaustion and enhanced responsiveness to ICIs.

Reducing Gamma Glutamyl Transferase after Steroid Administration in Biliary Atresia

Nurarifah Ali1,2, Rendi Prihaningtyas1,2, Bagus Setyoboedi1,2

1Dr. Soetomo General Academic Hospital, Faculty of Medicine, Universitas Airlangga, Surabaya, Indonesia
2Faculty of Medicine, Universitas Airlangga, Surabaya, Indonesia

Background: Biliary atresia is the leading cause of liver transplantation in children. Recent literature suggests that immune mechanisms are responsible for the pathogenesis of biliary atresia. This study aims to evaluate the effect of steroid therapy on Gamma Glutamyl Transferase (GGT) levels in biliary atresia.

Methods: A randomized control trial study was conducted on infants with biliary atresia. Methylprednisolone was administered at 2 mg/kg BW/day two times a day and Gamma Glutamyl Transferase was evaluated 2 weeks after the treatment. This study was analysed using SPSS ver 25.00.

Results: A total of 40 infants with biliary atresia between the ages of 2 weeks to 3 months (20 infants in the placebo group and 20 infants in the methylprednisolone group). There were no differences in bilirubin and liver function tests in the two groups (Methylprednisolone vs placebo: direct bilirubin 9.87 (6.11 - 14.20) mg/dL vs 6.68 ± 2.44 mg/dL; SGOT 176.54 ± 96.09 U/L vs 205.00 (135.25 - 280.25) U/L; p=0.05, but GGT level was lower in the methylprednisolone (160.50 (107.25 - 300.50) U/L) than placebo group (437 (157 - 1755.40) U/L; p = 0.028).

Conclusion: There is a reduction in GGT levels following administration of methylprednisolone. Methylprednisolone may have an effect in suppressing the inflammatory process in biliary atresia.

Abstract Submission No. 101066

Methylprednisolone Reduces MMP-7 as a Marker of Fibrosis Progression in Biliary Atresia

Syania Octariyandra1, Rendi Prihaningtyas1, Bagus Setyoboedi1

1Dr. Soetomo General Academic Hospital, Faculty of Medicine, Universitas Airlangga, Surabaya, Indonesia

Background: Chronic inflammation leads to fibrotic obliteration of the extrahepatic biliary tree in biliary atresia. Developing new therapies is necessary to reduce reliance on surgical intervention and liver transplantation. This study aims to evaluate the effectiveness of methylprednisolone (MP) versus placebo in reducing Matrix Metalloproteinase-7 (MMP-7) levels in biliary atresia.

Methods: Randomized, double-blind, placebo-controlled trial, 40 infants with biliary atresia received methylprednisolone (20) and placebo (20). An oral methylprednisolone (2 mg/kg/day) was given for 14 days. Laboratory measurements and MMP-7 levels were evaluated at weeks 0 and 2. Data analysis was performed using SPSS (Version 25).

Results: A total of 22 boys (55%) and 18 girls (45%) were involved in this study at a median age of 10 weeks (8 - 12 weeks). There were no differences in direct bilirubin and MMP-7 levels between the MP and placebo groups before treatment (9.87 [6.11 - 14.20] mg/dL vs. 6.68 ± 2.44 mg/dL; p=0.69 and 1.52 [1.12 - 1.67] ng/ml vs. 1.28 ± 0.54 ng/ml, p=0.394). MMP-7 levels after treatment were lower in the MP group (1.07 ± 0.48 ng/ml, p = 0.002) compared to the placebo group (1.55 ± 0.74 ng/ml, p = 0.040). The MP group has a higher level of reducing MMP-7 than the placebo group ($\Delta = 0.463 ± 0.592$ ng/ml vs. 0.267 ± 0.624 ng/ml, p = 0.040).

Conclusion: Methylprednisolone showed a significant reduction in MMP-7 levels. Anti-inflammatory drug may be effective in suppressing the inflammatory process resulting in fibro-oblitration in biliary atresia.

RCT Study in Biliary Atresia: Effect of methylprednisolone on liver function tests

Farahdina Farahdina1, Rendi Aji Prihaningtyas1, Bagus Setyoboedi1

1Child Health Department, Dr. Soetomo General Academic Hospital, Faculty of Medicine, Universitas Airlangga, Surabaya, Indonesia

Background: Biliary atresia is a fibrotic biliary obstruction. Although Kasai surgery has been performed, the need for Liver transplantation is still high. Pharmacologic treatment may be an alternative for the suppression of biliary fibrosis. This study aims to investigate the effect of steroids in liver function test in biliary atresia.

Methods: This study is a randomized controlled trial in infants with biliary atresia under three months. Subjects were divided into placebo and methylprednisolone. Methylprednisolone was given at a dose of 2 mg/kg/day for two weeks. A liver function test was performed prior to treatment and two weeks after treatment. The data were analyzed using SPSS.

Result: A total of 40 infants aged 9.5 (8 - 11.75) weeks were enrolled in the study, with 20 receiving placebo and 20 receiving methylprednisolone. The AST level was not different between placebo and MP before treatment (205.00 (135.25 - 280.25) vs 176.54 ± 96.09 U/L; p=0.99), but ALT level in the placebo group was higher than in the MP group (168 [113.75 - 313.25] U/L vs 83 [58.50 - 185.50] U/L; p=0.023). There was no difference in the reduction of AST and ALT levels between placebo and methylprednisolone groups (36.50 (-58 - 83.75) vs 18.5 ± 142.38 U/L; p=0.90 vs -91.64 ± 180 vs -14 (-133.5 - 5.25) U/L; p=0.38).

Conclusions: The administration of methylprednisolone did not have an effect on the reduction of AST and ALT levels. Liver function test may not be specified regarding biliary inflammation.

Keyword: Biliary atresia, Methylprednisolone, AST, ALT
Clinical utility of comprehensive genomic profiling tests for advanced biliary tract cancer.

Hiroki Inada¹, Hideaki Miyamoto¹, Hisanobu Oda², Moritaka Suga², Yoko Yoshimaru¹, Katsuya Nagaoka¹, Kentaro Tanaka¹, Satoshi Narahara¹, Sotaro Kurano¹, Takayuki Tokunaga¹, Etsuko Iio¹, Takehisa Watanabe¹, Hiroko Setoyama¹, Yasuhiro Tanaka¹

¹Department of Gastroenterology and Hepatology, Faculty of Life Sciences, Kumamoto University Kumamoto Japan, ²Department of medical oncology, Saiseikai Kumamoto Hospital Kumamoto JAPAN

Comprehensive genomic profiling (CGP) tests have become widespread in Japan since 2019. The range of treatment options for biliary tract cancer and other cancers is expanding. We report on the current status of CGP tests for biliary tract cancer at our hospital which is designated hospital, and another hospital which is cooperative hospital, for cancer genomic medicine in JAPAN. We retrospectively analyzed 71 patients who underwent CGP tests at our hospitals for biliary tract cancer by April 2023. Types of biliary tract cancers are as follows: intrahepatic cholangiocarcinoma 53.5%, extrahepatic cholangiocarcinoma 28.2% and gallbladder cancer 18.3%. In 71.8% of biliary tract cancers, treatment or clinical trials based on genetic mutations were recommended. Major genetic mutations in intrahepatic cholangiocarcinoma were as follows: \( KRAS \) mutation 21.1%, \( FGFR2 \) fusion 15.8%, \( IDH1 \) mutation 10.5%, and intrahepatic cholangiocarcinoma were as follows: \( KRAS \) mutation 30.0%, \( TP53 \) mutation 25.0%, \( BRCA2 \) mutation 10.0% and gallbladder cancer were as follows: \( KRAS \) mutation 15.4%, \( MDM2 \) amplification 15.4%, \( ERBB2 \) mutation 15.4%. On the basis of the CGP testing, 11 patients (15.5%) received targeted therapy. Among them, five patients (45.5%) received pemigatinib therapy for \( FGFR2 \) fusion gene. The overall response rate of pemigatinib therapy was 60%, with 3 patients having a partial response. These conducting CGP tests at a more appropriate time could provide patients with greater benefit from treatments based on their specific gene mutations in biliary tract cancer.

Diagnostic and prognostic significance of the PTEN gene in periampullary carcinoma.

Asgar Ali¹, Sadhana Sharma¹, Sundeep Saluja²

¹Department of Biochemistry, All India Institute of Medical Sciences Patna India, ²GIPMER New Delhi India

Objective: Periampullary Adeno Carcinoma is a heterogeneous carcinoma and is identified in its advanced stages. In periampullary tumours, the influence of a PTEN (phosphatase and tensin homolog) gene mutation on prognosis is unknown. The effect of PTEN downregulation and hypermethylation on the survival of periampullary cancer patients has yet to be investigated. As a result, we aimed to look into the expression value of PTEN gene as a potential biomarker.

Materials and Methods: One hundred and one tumour tissues from the patients were investigated for the mutational and expression of the PTEN gene. Sanger sequencing was used for molecular profiling, immunohistochemistry for protein expression, methylation specific PCR for methylation status, and anti-terminaldeoxynucleotidyltransferase biotin-dUTP nick end labelling test for programmed cell death (apoptosis). The changes were linked to clinicopathological features, overall survival and recurrence-free survival.

Results: In ampullary tumours, the clinicopathological relationship was significantly downregulated \((p=0.06)\), although hypermethylation \((p=0.08)\) and apoptosis loss \((p=0.06)\) were dramatically elevated in patients under 50 years of age. The ampullary tumour had a higher survival rate than the bile duct, duodenum, and pancreatic head cancers \((p=0.00)\). Furthermore, early stage T1 patients have a better prognosis than later stage T1 patients \((p=0.017)\). Patients who got adjuvant CTRT had a greater survival rate than those who did not \((p=0.010)\).

Conclusion: The absence of PTEN gene expression is detected in the ampullary subgroup of periampullary tumours. Those who have positive hypermethylation but modest expression has a poor overall survival. PTEN apoptosis-negative patients, on the other hand, had a higher survival rate.

HAIC, lenvatinib, and PD-1 inhibitors versus GC chemotherapy for advanced biliary tract cancer

Zhipeng Sun1, Bin Shu1, Yang Ming1, Zhizhong Ren1, Canhong Meier1
1Department of Radiology, The First Precision Medicine, The First Affiliated Hospital, Sun Yat-sen University Guangzhou China

Background: Gemcitabine and cisplatin (GemCis) plus durvalumab, a PD-L1 inhibitor, is the latest standard first-line therapy of advanced biliary tract cancers (BTCs). The efficacy and safety of GemCis chemotheraphy and PD-L1 inhibitors, in combination with lenvatinib have not been reported.

Methods: In this retrospective, single-center, single-arm study, patients with advanced BTCs who received GemCis plus PD-L1 inhibitors, durvalumab or enavolimab, with lenvatinib as first-line treatment were screened. The progression-free survival (PFS), overall survival (OS), objective response rate (ORR), disease control rate (DCR) and safety were evaluated.

Results: From December 2021 to July 2023, 43 advanced BTC patients with a median age of 60 years (range 35-79) were enrolled. Fifteen (34.9%) patients were over 65 years-old. The median duration of treatment was 5.0 months (IQR: 3.2 to 5.9), and the median duration of follow-up was 10.1 months (IQR: 6.6 to 12.2). According to mRECIST, the median PFS was 11.29 months and the median OS was 14.8 months. The 1-year PFS and OS rates were 45.9% and 61.4%, respectively. ORR and DCR were 48.8% and 95.3%, respectively. Any grade adverse events (AEs) occurred in all patients (100%) throughout the treatment. 60.46% (26/43) of the patients experienced grade 3 or 4 AEs. The most common grade 3 or 4 AEs were myelosuppression (37.2%) and hyponatremia (18.6%). No grade 5 AE occurred.

Conclusions: GemCis plus PD-L1 inhibitors with lenvatinib represents an effective and tolerable treatment option in advanced BTC patients, including the elderly patients. Further follow-up is ongoing.

Abstract Submission No. 100400

Choleodochal Cysts in Children- Clinical Spectrum

Arjun Maria1, Nishant Wadhwa1, Satish Aggarwal2, Alpana Prasad2
1Division of Pediatric Gastroenterology Hepatology and Liver Transplantation, Institute of Child Health,Sir Ganga Ram Hospital New Delhi India, 2Department of Pediatric Surgery, Sir Ganga Ram Hospital New Delhi India

OBJECTIVE: To study clinical spectrum of choledochal cyst (CDC) in children

METHODS: Records from January 2017 to May 2023 reviewed for children undergoing CDC excision with hepatico-jejunostomy

Results: Ninety two included with 34.8% males. Median age 36 (20-60) months. Type Ia (34.8%) most common, followed by Type Ib (33.7%), Type Ic (16.3%), Type Ivb (5.4%), Type Ic (3.3%), and Type II (3.3%) and formcfrust (3.3%). Recurrent pain abdomen (60.9%), vomiting (52.2%), jaundice (35.9%) were common symptoms, lump was in only 5 (5.4%). Fever in 28.3%. No difference in symptoms amongst the subtypes. Neontal cholestasis was in 17 (18.5%), with 10 children of Type Ia, 5 of Type Ia, 1 each of Type Ivb and formcfrust, however, its incidence was not different amongst the subtypes (p=0.158). GB stone in 20 (21.7%) with no association with any sub-type (p=0.590). CBD stone was in 33 (35.9%). It was more common with formcfrust subtype (100%) and Type Ivb (60%) as compared to other (Type Ia-25.8% vs Type Ic-45.7% vs Type II-33.3% vs Type Ia-34.4%), difference was not significant (p=0.106). CDC ruptured in 15.2% with no association with any subtype (p=0.795). Pancreatitis in 25%, no difference amongst subtypes (p=0.429). LCC was in 27.2% and more common in formcfrust (100%) and Type Ivb, Type Ic, Type II (33.3% each) than in Type Ia (16.1%) and Type Ivb (0%), but difference not significant (p=0.052).

CONCLUSION: Type Ia is the most common subtype with pain and jaundice most frequent symptoms. Neonatal cholestasis is a common presentation and pancreatitis and LCC must be looked for in all. Rupture is frequent (15%)
Abstract Submission No. 100885

Etiological spectrum of Paucity of intrahepatic bile duct (PIHBD) in infants

Alankrita Madhur1, Priti Vijay2, Dilip Ramrakhiani3

1Senior Resident, Department of Pathology, SMS Medical College & Attached Group of Hospitals Jaipur India, 2Assistant Professor, Department of Pediatric Medicine, Sir Padampat Institute of Neonatal and Pediatric Health, SMS Medical College Jaipur India, 3Senior Professor, Department of Pathology, SMS Medical College & Attached Group of Hospitals Jaipur India

Background and objectives: Ductal paucity is one of the important differential diagnosis of infants presenting with cholestasis. PIHBD is defined as bile duct to portal tract ratio< 0.6. In the study we aimed to identify all the causes of ductal paucity in infants.

Methods: From June 2021 to June 2023 all the liver biopsies done in children <1 year old were screened. Of the total 150 liver biopsies, 100 were of infants, out of them 13 had ductal paucity.

Results: Out of total 13 liver biopsies, 6 were of females. Median age (days, IQR) at the time of biopsy was 75 (55-156). Median bilirubin, GGT, albumin (Median, IQR) was 9 (5-13), 178 (156-202), 3.5 (3-3.9) respectively. Of the total 13 biopsies with PIHBD, 5 were of progressive familial intrahepatic cholestasis, 1 was of hypopituitarism, 1 was of cystic fibrosis, 1 was of Alagille syndrome, 1 was of Zellweger syndrome and 4 were of prematurity related in which sepsis and respiratory distress was indication of admission. Out of 13 patients, 3 showed poor outcomes (Zellweger syndrome, Alagille syndrome and one infant with prematurity).

Conclusion: Ductal paucity encompasses 13% of etiology of infantile cholestasis. It generally had favourable outcomes, so timely diagnosis and intervention is necessary. Liver biopsy is confirmatory diagnostic modality.
Genomic profile characteristics of pancreaticobiliary maljunction, including cancer patients

Shodai Tohyama1,2, Hiroshi Ohyama1,2, Kenji Amemiya2,3, Yosuke Hirotsu2, Miho Sakai0, Takashi Mishima4, Tsukasa Takayashiki4, Hitoshi Mochizuki2, 5, Masayuki Ohtsuka4, Naoya Kato1, Masao Omata0

1Department of Gastroenterology, Chiba University Hospital Chiba Japan, 2Genome Analysis Center, Yamanashi Prefectural Central Hospital Yamanashi Japan, 3Department of Pathology, Yamanashi Prefectural Central Hospital Yamanashi Japan, 4Department of General Surgery, Chiba University Hospital Chiba Japan, 5Department of Gastroenterology, Yamanashi Prefectural Central Hospital Yamanashi Japan, 6University of Tokyo Tokyo Japan

Background: Pancreaticobiliary maljunction (PBM) is known to be a high-risk factor for biliary tract cancer (BTC). It has been reported that TP53 and KRAS mutations are found not only in the cancerous area but also in the noncancerous area. However, genetic studies on PBM have been insufficient.

Methods: Patients who underwent surgical resection for PBM and BTC between 1990 and 2023 at our hospital and affiliated hospitals were included in this study. FFPE tissue samples were sampled from different histological types (normal mucosa, hyperplasia, dysplasia, and carcinoma) by laser microdissection, and targeted sequencing was performed using the panel targeting 60 genes frequently identified in BTC, and compared with clinicopathological features.

Results: PBM patients with BTC showed various functional gene abnormalities, including driver mutations such as TP53 and ARID2, not only in the carcinoma but also in the non-cancerous areas including hyperplasia and normal cholangiocarcinoma mucosa. On the other hand, driver mutations were also found in some areas in patients who did not develop gallbladder cancer (prophylactic resection), but were rare. In addition, driver mutations were rarely found in non-cancerous areas in patients with BTC without PBM.

Conclusions: PBM patients with BTC showed a great variety of genetic abnormalities in both cancerous and noncancerous areas. On the other hand, in patients of prophylactic resection without cancer, driver mutations were almost completely absent despite the presence of mucosal changes. We believe that these findings can develop better strategies in patients with PBM.

Carcinoma, a rare malignant neoplasm of the biliary duct: A case report

Ariane Crizelle Jose-Baluyot1, Karl Yu Kim Teng1

Carcinosarcoma is a rare malignant biphasic tumor with both carcinoma component and a spindle cell sarcomatous component intimately intermingled. As published by the World Journal of Gastrointestinal Oncology, there are only 12 cases reported worldwide. We report a case of a 63-year-old Filipino presenting with 10-day history of jaundice, right upper quadrant pain, and weight loss. Preliminary work-up showed, transaminisits, hyperbilirubinemia, negative hepatitis profile, and elevated CA19-9 (1007.70 U/mL). Whole abdomen MRI showed high-grade hepatic hilar obstructive process with marked intrahepatic ductal dilatation secondary to poorly defined soft tissue in the common hepatic duct region measuring 1.2 cm with small (<1.0 cm) porta hepatis & perportal as well as retroperitoneal & bilateral inguinal lymph nodes and normal common bile duct. He underwent Endoscopic retrograde cholangiopancreatography with Spyglass cholangioscopy, with the following findings: nodular and hyperemic lumen with a stricture seen in the said area. Multiple biopsies were taken. Histopathology of proximal common bile duct and common hepatic tissue (diagnosis concurred with 3 other pathologists) revealed: biphasic neoplasm suggestive of a carcinosarcoma. Since R0 resection was not feasible, patient underwent systemic chemotherapy (gemcitabine-based) targeting both lineages (carcinoma and sarcoma). Currently, patient is on his 12th cycle of chemotherapy and for re-evaluation for resectability.

Correlation of Serum Matrix Metalloproteinase-7 and Liver Function Test in Biliary Atresia

Muhammad Irawan1, Rendi Ahja Prihaningtyas2, Bagus Setyobodoi3

1Soetomo General Hospital Surabaya Indonesia, 2Soetomo General Hospital Surabaya Indonesia, 3Soetomo General Hospital Surabaya Indonesia

Background: Biliary atresia (BA) is a rare progressive infant cholangiopathy characterized by cholestasis. BA is a leading cause of pediatric liver transplantation. Early diagnosis using sensitive biomarkers is crucial for good outcomes. However, at present, there is no certain non-invasive diagnostic method to diagnose and differentiate it from other cause of cholestasis. The aim of this study was to evaluate the correlation of serum matrix metalloproteinase-7 (MMP-7) levels with laboratory parameters.

Material and Methods: This cross-sectional study included infants with biliary atresia who were admitted to Soetomo General Academic Hospital, Surabaya. Blood samples as well as baseline clinical and demographic data were collected when admitted. Serum MMP-7 levels were determined by enzyme-linked immunosorbent assay. Result: There were 85 infants with biliary atresia, mean age 11 (1 - 35) weeks, 46 (54.1%) boys, with onset of jaundice at 2 (1 - 20) weeks. The MMP-7 levels were 1.91 (0.39 - 9.95) pg/dl, 4.06 (1.41 - 4.79) g/dl, AST 235.37 ± 130.48 U/L, ALT 143.2 (30 - 641) U/L, 361 (23.9 - 3746) U/L, direct bilirubin 8.75 ± 4.28 mg/dl, and total bilirubin 12.34 ± 6.36 mg/dl. MMP-7 showed a positive correlation with albumin levels (r=0.232; p=0.033), but correlated negatively with AST (r=-0.252; p=0.020) and ALT (r=-0.275; p=0.011) levels. Direct or total bilirubin, hemoglobin, leukocyte or platelet levels were not associated with MMP-7 (p>0.05).

Conclusion: There is positive correlation between MMP7 and albumin, but the relationship between MMP and serum transaminases is reversed. MMP-7 may be used as a prognostic marker for liver damage.
A two-stage anticancer strategy targeting ECM stiffness in primary liver cancer
Shen Zefeng1,2,3, Tao Liye1,2,3, Shangguan Liqing1, Wang Yali1,2, 3, Pan Haoyu4, Cai Jingwei1,2,3, Zheng Junhao5, Liu Yang1,2,3, Lin Xianfeng1, Xu Junjie6, Liang Xiao6

1Department of General Surgery, Sir Run-Run Shaw Hospital, Zhejiang University School of Medicine, Hangzhou, 310016, China
2Zhejiang University Cancer Center Hangzhou China
3Zhejiang University School of Medicine Hangzhou China

Background: Intrahepatic cholangiocarcinoma (ICC) has a stiffer extracellular matrix (ECM), higher malignancy, and worse prognosis compared to hepatocellular carcinoma (HCC). This study aimed to explore relationships between ECM stiffness and primary liver cancers (PLC, including HCC and ICC) and develop anticancer strategies targeting ECM stiffness in PLC (ICC especially).

Methods: We first explored relationships between ECM stiffness and malignant phenotypes of PLC through in-vitro and in-vivo experiments. Next, we took functional molecules related to ECM stiffness in ICC as examples to explore specific mechanisms of the intracellular response of cancer cells to ECM mechanical signals. Finally, we newly constructed nanoparticles (NPs) and extracted ICC membrane (ICCM) to camouflage cationic polymers for siRNA and BAPN (ICCM@NPs-siRNA@BAPN) to achieve ICC-specific targeted delivery.

Results: The immunofluorescence results of 181 PLC tissue chips (HCC=90, ICC=91), in-vitro and in-vivo experiments showed that ECM stiffness could affect malignant phenotypes of PLC (ICC especially). The new transcript of ABHD11-AS1, a functional IncRNA related to ECM stiffness in ICC, regulated malignant phenotypes of ICC cells and their response to ECM mechanical signals through the YAP1/ABHD11-AS1/STAU2/ZYX/YAP1 loop signaling pathway. ICCM@NPs-siABHD11-AS1@BAPN could be a two-stage anticancer strategy targeting ECM stiffness in ICC.

Conclusions: This study demonstrated that ECM stiffness could affect malignant phenotypes of PLC (ICC especially) and took the YAP1/ABHD11-AS1/STAU2/ZYX/YAP1 loop signaling pathway as the entry point to explore specific mechanisms of mechanical signals conduction from ECM in ICC cells and their impact on cancer progression. Moreover, ICCM@NPs-siABHD11-AS1@BAPN was a spatially selective delivery system integrating ECM softening and blockade of intracellular mechanical signal transduction in ICC.

A 70-year-old woman with history of gallbladder intracholecystic papillary neoplasm (ICPN) presented with persistent melena with anemia (hemoglobin 6.2 g/L). Prior endoscopies did not show any actively bleeding lesions. On admission, patient presented with melena, mild epigastric pain, and pallor. A second look EGD revealed hemobilia. Patient underwent mesenteric angiogram, particle embolization of selected arteries and intraoperative ultrasound revealed multiple hepatic heterogenous foci. Whole abdominal CT scan revealed no hepatic mass lesions, common bile duct (CBD) and intrahepatic duct (IHD) dilatation and a 1cm nodular enhancing focus in the proximal CBD. Spyglass cholangioscopy revealed a lobulated polypoid lesion with villous surface at the main right IHD. Patient underwent choledochoscopy with laser ablation of multiple IHD tumors, excision of IHD mass, and t-tube cholecystostomy. Frozen section revealed mucinous IPNB, predominantly low grade with focal high-grade dysplasia. Due to persistence of melena, patient underwent angiogram with embolization of hepatic arteries; percutaneous transhepatic biliary drainage (PTBD). Although with initial improvement, patient eventually expired after 6 months. In our case, the hemobilia may be due to the diffuse and infiltrative nature of the tumor into adjacent liver parenchyma and vasculature. The co-occurrence with ICPN may be contributory. IPNB has relatively good prognosis hence need for early surgical management. Apart from surgery, other treatment options such as laser ablation, PTBD and embolization need to be explored further.

Extra-hepatic bile duct resection in cases with intrahepatic cholangiocarcinoma
Tian-Run Lv

1West China Hospital of Sichuan University Chengdu China

Abstract

Objective: To evaluate the significance of combined extra-hepatic bile duct resection (EHBDR) in cases with intrahepatic cholangiocarcinoma (IHCC) in terms of clinic-pathological features and long-term survival.

Methods: Radically-resected cases with IHCC from 2000 to 2020 were identified from Surveillance, Epidemiology, and End Results (SEER) database. Comparative analyses were performed between resected IHCC patients who received EHBDR and those without EHBDR.

Results: A total of 1521 radically-resected cases with IHCC (189 cases received EHBDR) were included. Comparable age, sex, race, marital status, liver cirrhosis, differentiation status, and adjuvant chemotherapy were acquired between two groups. EHBDR achieved a greater lymph node yield (P<0.001). The incidence of cases with T3-4 or N+ disease was significantly higher in the EHBDR group (P<0.001). Adjuvant radiotherapy was more frequently performed in cases with EHBDR (P<0.001). Even various independent prognostic factors have been matched between two groups, cases in the EHBDR group still shared a much worse prognosis than those without EHBDR. For early-staged cases, combined EHBDR was even harmful. However, for more advanced cases, EHBDR achieved equivalent survival versus those without EHBDR.

Conclusion: Combined EHBDR was not associated with any survival benefit in radically-resected cases with IHCC and was even harmful for some early-staged cases. However, a greater lymph yield was achieved via EHBDR. Future well-designed studies with more detailed data, such as recurrence rate within 6 months after surgery and the time from the date of surgery to the date of the occurrence of obstructive jaundice, are warranted for further exploration.
Cholangiocarcinoma (Bismuth Corlette Class I) secondary to Choledochal Cyst (Todani Type II)

Choledochal cysts are a rare congenital abnormality of the biliary tree, characterized by a wide spectrum of clinical manifestations, ranging from asymptomatic to life-threatening complications. The reported incidence of Choledochal cysts is approximately 1:100,000 to 1:1,000,000 in the general population. Choledochal cysts are classified into five types: Type I (diverticulum), Type II (common bile duct diverticulum), Type III (choledochocoele), Type IV (multiple intrahepatic and extrahepatic cysts), and Type V (Caroli disease). Type II cysts are the most common type, accounting for about 70% of all cases. Type II cysts are typically associated with biliary strictures, bile duct dilatation, and the presence of stones.

We report herein a case of a previously healthy 33-year-old Filipino male who complained of a 1-month history of colicky abdominal pain, and 2-weeks history of jaundice, icteric sclera, tea-colored urine, acholic stools. Patient was initially diagnosed as obstructive jaundice probably secondary to choledocholithiasis through ultrasonography. ERCP revealed multiple filling defects within of what seems to be the gallbladder, a narrowing at the proximal CBD with preferential flow of contrast to the gallbladder, and a cystic structure beside the gallbladder. Upper abdominal MRI with MRCP revealed a choledochal cyst type II with intraluminal stones and a contracted gallbladder. Patient underwent biliary exploration which revealed a CBD tumor and a choledochal cyst with multiple intraluminal stones. Core needle biopsy of the tumor revealed poorly-differentiated adenocarcinoma. Patient was diagnosed as Perihilar Cholangiocarcinoma (Bismuth Corlette Class I) secondary to Choledochal Cyst (Todani Type II) with Lithiasis.

Clinical impact of bile cytology and surgical site complication on locoregional recurrence in eCCA.

Yoshiro Ito1, Daisaku Yamada1, Shogo Kobayashi1, Kazuki Sasaki1, Yoshifumi Iwagami1, Yoshio Tomimaru1, Takehiro Noda1, Hidenori Takahashi1, Yuichiro Doki1, Hidetoshi Eguchi1
1Department of Gastroenterological Surgery, Graduate School of Medicine, Osaka University Suita Japan

Background: Choledochocarcinoma is a lethal malignancy with a poor prognosis because of its high rate of recurrence after radical resection. In terms of prevention of recurrence, the intraductal irradiation of the remnant rectum prior to anastomosis decreased local recurrence in rectal cancer. The presence of surgical site complications (SSC) is regarded as a risk factor for the recurrence in other cancers. However, there have been few studies similar to this in extrahepatic cholangiocarcinoma (eCCA). We here investigated whether preoperative positive bile cytology and postoperative complications were associated with recurrence in eCCA.

Method: Ninety-six patients who underwent R0 resection for eCCA in our hospital were investigated. The relationship between clinicopathological factors and long-term outcomes was evaluated.

Result: 42 patients had SSC including bile leakage. Preoperative bile cytology was positive (Class IV, V) in 50 patients except for 13 patients who had not undergone bile cytology. Recurrence at the peritoneum and local site was significantly more frequent in the SSC group than in the non-SSC group (42.8%:11.1%, p=0.0003). While the occurrence of SSC was not associated with preoperative bile cytology-positive cases (p=0.4980), bile cytology-positive patients with SSC had a higher rate of peritoneum and local recurrence than the other patients (72.2%:13.9%, p=0.0001). Both preoperative positive bile cytology and the presence of SSC were significant factors of recurrence-free survival (RFS) (p=0.0096,0.0175).

Conclusion: Preoperative positive bile cytology is a risk factor for recurrence in eCCA. Furthermore, adding the factor of SSC, the peritoneal or local recurrence was more frequently observed.

ADC values predict prognosis and Ki67 expression in intrahepatic cholangiocarcinoma on DW-MRI

Daiki Hokkoku1, Kazuki Sasaki1, Shogo Kobayashi1, Yoshifumi Iwagami1, Daisaku Yamada1, Yoshio Tomimaru1, Takehiro Noda1, Hidenori Takahashi1, Yuichiro Doki1, Hidetoshi Eguchi1
1Department of Gastroenterological Surgery, Graduate School of Medicine, Osaka University Suita Japan

Background: Ki67 is a marker of cell proliferation and key in cancer treatment because it reflects the grade and prognosis of malignant tumors. Apparent diffusion coefficient (ADC) values are derived from DWI and are a common imaging metric used to quantify the biological behavior of tumors and evaluate curative response. ADC values have been associated with Ki67 expression in breast cancer and pancreatic neuroendocrine tumors, but information about the relationship between Ki67 expression and ADC values in ICC is lacking.

Method: We investigated the ability of ADC values to predict Ki67 expression, using retrospective analysis of 39 cases of ICC confirmed by surgical pathology. All patients had undergone MRI, and ADC values (mean, minimum, maximum) were calculated. Ki67 expression was assessed by immunohistochemistry, and patients were divided into groups of high (n = 13) and low Ki67 expression (n = 26). To assess the diagnostic performance of the ADC values for Ki67 expression, we used the receiver operating characteristic curve and compared the areas under the curve (AUCs).

Results: The high Ki67 expression group had a significantly poorer prognosis than the low group. The minimum ADC values were significantly lower in the group with high Ki67 expression. For predicting high Ki67 expression, the AUC values were 0.7189 for the minimum ADC values. The diagnostic sensitivity and specificity of the minimum ADC values were 84.6% and 73.1%, respectively. In addition, with ADC values combined, the AUC increased to 0.760.

Conclusion: ADC values can non-invasively predict ICC associated with high Ki67 expression.

A case of cystic pseudo-tumor as a complication of radiofrequency ablation therapy

O-0900

A case of cystic pseudo-tumor as a complication of radiofrequency ablation therapy
Radiofrequency ablation (RFA) therapy is a curative treatment for small-sized hepatocellular carcinoma (HCC) tumors. It is widely performed at many institutions worldwide, and its complications have been well discussed in previous studies. Here, we report a highly rare case of cystic pseudo-tumor as a complication of RFA treatment. The patient was a 71-year-old individual with HCC who had an etiology of non-alcoholic steatohepatitis. He also had hypertension, type 2 diabetes, chronic renal failure on dialysis, prostatic cancer, and a history of hepatectomy for HCC. We performed RFA therapy for HCC recurrence in the left lobe near the stomach. Four months later, we identified the formation of a cystic lesion in the treated area of the liver without any symptoms. This cystic lesion was surrounded by a thick wall. Cytodiagnosis of the fluid within the cystic lesion revealed that the fluid was serous and not purulent. Total bilirubin levels of the fluid were not elevated, and no evidence of malignancy was found. Computed tomography examination at 16 months after RFA showed a collapse of the cystic lesion, and small amounts of gas were detected in the RFA-treated lesion, indicating that penetration of the stomach had occurred. Artificial ascites could not completely prevent gastrointestinal tract injury, but would be necessary to keep thermal injury to minimum in ablation therapy.

Gastric adenocarcinoma with enteroblastic differentiation (GAED) is a rare special type of gastrointestinal tumor. Our patient had a history of CHB with cirrhosis for more than 25 years and underwent 13 years combination therapy for HCC, like RFA and TACE, besides targeted drugs for 4 years. GAED was found in the greater curvature of upper segment of gastric body. The gastric and duodenal background mucosa was slightly edematous with regular dilation of microvessels. We suspect it’s caused by targeted drugs. The lesion consists of two parts, 0-IIa+1 Ib. Fine villous white fur epithelium showed a distinctive appearance in Faded flat area. Biopsy specimens taken from the lesion in the 0-IIa reddish position revealed to low-differentiated adenocarcinoma. The lesion removed by using endoscopic submucosal dissection. The lesion located in the mucosal layer, and the small infiltrated the submucosa to 196um. The irregular carcinomatous adenoids are tubular and cystadenoid, similar in shape to common intestinal adenocarcinoma components. Part of the region was solid, the epithelial cells were cubic, the atypia was significant, and the cytoplasm was transparent and vacuole-like. The patient survived with high quality at the fourth month after surgery. Through comprehensive and diverse treatment methods, the survival of patients is prolonged. Multidisciplinary collaborative treatment significantly improves the quality of life of patients.

Acute liver failure by scrub typhus; a rare presentation
Sudhamshu KC1, Niyanta Karki2, Pukar Thapa1,2
1National Academy of Medical Sciences Kathmandu Nepal, 2Norvic International Hospital Kathmandu Nepal

Acute liver failure (ALF) can be due to numerous causes and result mostly in mortality if liver transplantation cannot be offered. Scrub typhus is an acute febrile disease caused by Orientia tsutsugamushi transmitted by mites. Liver injury in scrub typhus is common but reversible. However, there are reported cases of ALF due to scrub typhus, mainly in conjunction with other clinical conditions. Herein we report a case who presented with scrub typhus complicated by ALF and treated successfully without transplantation in our institute. A 27-years-old lady was admitted with complaints of jaundice and fever. LFT showed bilirubin of 10.2/8.4 mg/dL with ALT/AST of 1058/2134 IU/mL. A working diagnosis of acute viral hepatitis was made. Viral serology for HAV, HEV, HBV, HCV, TORCH were negative. Patient developed seizure followed by encephalopathy and INR came out to be 3. Patient was transferred to ICU and counselled for liver transplantation. Due to non-availability of donor, transplantation was not carried out. Patient slowly improved with conservative management but her fever was persistent. Fever panel test was sent and scrub typhus IgM came to be positive. Patient was put on doxycycline. Fever came down but liver enzymes worsened. Antibiotics changed to Azithromycin and patient improved. After a hospital stay for 29 days she was discharged. Due to the non-specificity and diversity of the initial presenting symptoms, scrub typhus causing ALF can easily be missed. A lack of awareness about the disease and its role in causing ALF, there is always a chance of misdiagnosis.
Case Report: A 28-year-old gentleman visited the outpatient clinic because of recently known HBV infection 8 years ago. He had history of HBV Vaccinations 10 years ago, but no immune response of HBs Ag detected. His serological testing were positive for HBs Ag, HBe Ab, and HBs Ab, HBe Ag and HBe Ab (both IgM and IgG) were negative. HCV Ab and HIV Ab were also negative. HBV DNA - 1.19E + 04 IU/mL and qHBs Ag 584 IU/ml. ALT - 66 IU/mL, AST 70 IU/mL, AFP - 3.5 IU/mL.

Utrasound Abdomen showed chronic hepatitis. Fibroscan showed F3 fibrosis and moderate steatosis. He was admitted to the hospital with a diagnosis of severe acute hepatitis. He was discharged on the 22nd day of hospitalization.

Cytokine release syndrome caused by the durvalumab plus tremelimumab combination therapy for HCC

Sae Yumita1, Sadahisa Ogasawara1, Yumi Ozaki1, Takuya Yonemoto1, Keisuke Koroki1, Masanori Inoue1, Kazufumi Kobayashi2, Naoya Kanogawa1, Soichiro Kiyono1, Msato Nakamura1, Takayuki Kondo1, Shingo Nakamoto1, Naoya Kato1
1Department of Gastroenterology, Graduate School of Medicine, Chiba University, Japan Chiba-shi, Chiba-ken Japan

Background: Cytokine release syndrome (CRS) is a systemic inflammatory syndrome that can lead to life-threatening, caused by elevated levels of cytokines and the activation of immune cells. It can be triggered by systemic therapies mainly immune activating treatments, pathogens, malignancies, or autoimmune diseases. In recent years, CRS has been reported as an immune-related adverse event associated with immune checkpoint inhibitor. We report a case of severe CRS that occurred following the initiation of durvalumab plus tremelimumab combination therapy for advanced hepatocellular carcinoma (HCC).

Case Report: A combination therapy of durvalumab plus tremelimumab was initiated in a 35-year-old female with stage IV metastatic HCC. A few weeks later, she visited our department due to a fever. She had low blood pressure and a body temperature of 39℃. Blood tests revealed signs of inflammation, elevated transaminases, and renal impairment. Suspecting sepsis, broad-spectrum antibiotics and vasopressors were initiated. While the vasopressors could be continuously given, the high fever persisted, and liver enzymes continued to rise, leading to a tendency toward disseminated intravascular coagulation. Given the elevated IL-6 levels, we considered the possibility of CRS and administered steroid pulse therapy. The patient’s overall condition began to improve and we began tapering the steroids. However, a few days later, with the re-elevation of IL-6 and CRP levels, we suspected a recurrence of CRS and administered tocilizumab. Subsequently, her condition showed improvement and she was discharged on the 22nd day of hospitalization.

Conclusion: Severe CRS has the potential to become life-threatening, so appropriate therapeutic interventions are necessary.

Abstract Submission No. 100455

Recovery of Severe Acute Hepatic Graft-versus-Host Disease in a Recently Transplanted Pre-B Cell ALL

Ma. Regina D. Dimaculangan1, Faith Abigail Co1, Alexandra Layas1
1Institute of Digestive and Liver Diseases, St. Luke's Medical Center - Global City Taguig Philippines

Introduction: Acute Graft-versus-Host Disease (GVHD) is a complication among hematopoietic cell transplant recipients within 100 days. But only around 9% involve both the liver and the gastrointestinal tract. Diagnosing hepatic GVHD is quite challenging, since it is indistinguishable from other disorders such as infection and drug-induced liver injury.

Clinical Significance: Hepatic GVHD has a higher non-relapse mortality rate than non-hepatic. However, early recognition and management even without a liver biopsy can help prevent the development of permanent organ damage.

Case Report: Here we present a case of a 57-year-old female, with pre-B cell acute lymphoblastic leukemia and with no known liver disease, who underwent allogeneic HSCT (mismatched/haploidentical) two months prior to admission. Patient was managed as a case of pneumonia in an immunocompromised host. At Day +83 post-transplant, she presented with high grade fever, diarrhea, generalized jaundice, and vomiting. She was diagnosed with acute hepatic graft-versus-host-disease through elevated bilirubins and late increase in transaminases (Grade 0). This eventually progressed to Grade 4 in a span of 17 days with the highest total bilirubin and direct bilirubin recorded to be 33
mg/dL and 24 mg/dL, respectively. Patient was then started on high dose steroids and liver supportive therapy, such as minophagen drip, transmetil, udacacid, and silymarin. Her liver profile started to down trend after 25 days, and noted clinical improvement of symptoms.

**Conclusion:** Elevated bilirubins, rather than increase in transaminases, is the best diagnostic marker for Hepatic GVHD. Prompt administration of steroids can help improve the patient’s overall survival.

**Unmasking Hepatoid Adenocarcinoma of the Stomach Mimicking as Hepatocellular Carcinoma: A Case Report**

Laurence Laurel1, Jozen Lagman1, Joseph Bocobo1, 2
1St. Luke’s Medical Center- Global City Taguig Philippines, 2St. Luke’s Medical Center- Quezon City Quezon City Philippines

Hepatoid adenocarcinoma of the stomach (HAS) is a rare malignancy characterized by its hepatocellular differentiation and aggressive nature. Due to its scarcity and vague clinical presentation, diagnosing HAS poses significant challenges, often leading to its misidentification as hepatocellular carcinoma due to their indistinguishable radiologic and clinical parameters.

We report a 68-year-old male who initially sought consult for a perplexing symptom: a persistent three-week history of hiccups. During an abdominal ultrasound, solid hepatic nodules were incidentally discovered, triggering further investigations. Subsequent tests unveiled a dramatic elevation in alpha-fetoprotein (AFP) levels (~60,000 ng/mL) and the presence of hypovascular hepatic masses, accompanied by portal vein thrombosis, as evident on a 4-phased dynamic liver scan. The initial suspicion was hepatocellular carcinoma, primarily due to an atypical enhancement pattern observed. To explore the anomaly further, a fine needle aspiration biopsy of the liver mass was performed. Notably, given the unusual initial symptom of hiccups and anemia, gastro-duodenoscopy was done revealing an unexpected gastric mass located in cardia up to the esophagus. Histopathological analyses of both the liver and gastric masses, supplemented by immunohistochemical stains, ultimately confirmed the diagnosis of gastric adenocarcinoma with liver metastasis. This case emphasizes the significance of a comprehensive diagnostic approach for rare conditions such as HAS with liver metastasis, highlighting the need for integrating clinical, radiological, and histopathological findings. It underscores the importance of considering HAS as a potential differential diagnosis in cases of AFP-producing liver lesions that exhibit atypical hepatocellular carcinoma imaging characteristics.

**O-0908**

A case of neuroendocrine carcinoma caused obstructive jaundice by extensive hepatic infiltration.

Chihei Sugihara1, Motoyasu Kan1, Miho Sakai1, Kazuki Watabe1, Tomoya Takahashi1, Yu Sekine1, Syodai Tohyama1, Nana Yamada1, Mayu Ouchi1, Motoyasu Kan1, Hiroki Nagashima1, Koji Takahashi1, Kouichirou Okiitsu1, Izumi Ohno2, Toyozumi Takeshi1, Hisahiro Matsubara1, Naoya Kato1
1Department of Gastroenterology, Graduate School of Medicine, Chiba University Chiba Japan, 2Department of Medical Oncology, Graduate School of Medicine Chiba Japan

A 74-year-old man was found to have obstructive jaundice (T-Bil 18.6 mg/dL). He had a history of total gastrectomy and Roux-en-Y anastomosis for upper gastrointestinal bleeding in his 20s. Imaging findings showed that the tumor was 80mm which extensively infiltrated to both lobes of liver, gallbladder, duodenum, and main portal vein and caused biliary stricture classed Type3A in Bismuth classification. Biliary drainage was attempted using a balloon endoscopy, but it cloud not reach Vater papilla. Next, percutaneous transhepatic bile duct drainage was performed to posterior segmental branch, but jaundice did not improve. An endoscopic ultrasound-guided hepatic jejunostomy for obstructive jaundice caused by hepatic infiltration are rare. And in this patient, there was difficulty on biliary drainage for reconstructed intestinal tract. However, we finally succeeded in improving jaundice by combination of percutaneous procedure and interventional EUS.

Abstract Submission No. 100541

A case of cholangitis as immune-related adverse events with biliary infection after cholangiography.

Chihei Sugihara1, Hiroshi Ohyama1, Tomoya Takahashi1, Yu Sekine1, Shodai Tohyama1, Nana Yamada1, Mayu Ouchi1, Motoyasu Kan1, Hiroki Nagashima1, Koji Takahashi1, Kouichirou Okiitsu1, Izumi Ohno2, Toyozumi Takeshi1, Hisahiro Matsubara1, Naoya Kato1
1Department of Gastroenterology, Graduate School of Medicine, Chiba University Chiba Japan, 2Department of Medical Oncology, Graduate School of Medicine Chiba Japan

**Background:** Immune checkpoint inhibitors possibly cause immune-related adverse events (irAE). The rate of sclerosing cholangitis in irAE is small, but it is reported difficult to cure immune checkpoint inhibitor-induced cholangitis because steroid therapy has no efficacy for them.

**Case:** 75-year-old-man had had a history of subtotal esophagectomy for esophageal cancer at age 71. He was performed multidisciplinary treatment involving Nivolumab therapy for lung metastasis from age 73. During hospitalization of treatment for ulcer in a reconstructed gastric tube perforating the pericardium, he was found to have jaundice (T-Bil 13.7 mg/dl) on day 46. Imaging findings showed that non-continuous strictures of wide part of bile tract with dilation of upper bile duct. It was suspected sclerosing cholangitis, so an endoscopic retrograde cholangiopancreatography (ERCP) was performed. It showed that pruned-tree appearance by cholangiography and circular homogenous wall thickening of parts of bile duct with stricture by intraductal ultrasound. Bile cytology and brush cytology from stricture were not malignant. After balloon dilation of stricture, an endoscopic nasobiliary drainage tube was put, but it was removed soon. This patient was diagnosed as an immune checkpoint inhibitor-induced cholangitis because steroid therapy has no efficacy for them.

**Conclusion:** For the treatment of immune checkpoint inhibitor-induced cholangitis, the indication of steroid therapy was limited.
Corticosteroid therapy for prolonged jaundice and pruritus in HIV patients with acute hepatitis A

Michiko Koga, Lay Ahyoung Lim, Hiroshi Yotsuyanagi

1The Institute of Medical Science, University of Tokyo Tokyo Japan, 2Kitasato Institute Hospital, Kitasato University, Tokyo, Japan Tokyo Japan

Background: Recent years have seen global outbreaks of acute hepatitis A (HA), particularly affecting men who have sex with men (MSM). In Tokyo in 2018, an outbreak primarily impacted MSM, including some individuals living with HIV (PLWH). Two PLWH experiencing prolonged jaundice and severe pruritus were treated with corticosteroids, demonstrating successful responses. This marks the first report of corticosteroids for prolonged cholestatic HA in PLWH.

Cases: The first case involved a 34-year-old male, on antiretroviral therapy (ART) for six years. Despite CD4 count of 527/µl and suppressed HIV-RNA viral load, he faced elevated peak ALT 3494 IU/l and total bilirubin (T-Bil) 31.9 mg/dl. Severe itching and fatigue led to the initiation of 25 mg/day (0.5 mg/kg) of prednisolone (PSL) on day 62. T-Bil levels gradually normalized by day 142.

In the second case, a 36-year-old male, 11 years on ART with CD4 count 620/µl and suppressed HIV-RNA viral load, encountered peak ALT 2690 IU/l and T-Bil 22.8 mg/dl. Despite well-managed HIV, he too experienced itching and fatigue. Initiation of 30 mg/day (0.5 mg/kg) of PSL on day 32 resulted in a T-Bil decrease of 2.1 mg/dl by day 71.

Discussion: Around 1% of HA cases may lead to prolonged jaundice and severe itching. Cholestasis might arise from various bilirubin metabolism defects. This study suggests that corticosteroid therapy could be an effective option for well-controlled PLWH on ART.

Detection of ETV-associated drug resistance mutation S202G in a case of HBV/HIV coinfection

Michiko Koga, Kazuaki Takahashi, Tadashi Kikuchi, Takeya Tsutsumi, Hiroshi Yotsuyanagi

1The Institute of Medical Science, University of Tokyo Tokyo Japan, 2AIDS Research Center, National Institute of Infectious Diseases Tokyo Japan, 3Graduate School of Medicine, The University of Tokyo Tokyo Japan

Background: Entecavir (ETV) resistance is often acquired following lamivudine (3TC) resistance but is rarely proven by clinical specimen analyses over time. A case study outlines the gradual acquisition of the S202G mutation spanning approximately 8 months.

Case: A man in his 40s, diagnosed with HIV/AIDS and chronic hepatitis B eight years ago, initially received tenofovir/emtricitabine (FTC)/darunavir/ritonavir. Subsequently, HIV-RNA and HBV-DNA were suppressed, and CD4 counts increased. Later, due to renal issues, he was switched to abacavir/dolutegravir (DTG) and ETV. Upon transfer to our clinic three years ago, he exhibited suppressed HIV-RNA, CD4 count 635/µl, normal transamidases, HBsAg 245.38 IU/ml, HBV-DNA 2.6 log IU/ml, and HBV genotype A2. Subsequently, reaching AST 40U/L, ALT 70U/L, HBsAg exceeding 99999.99 IU/ml, and HBV-DNA rising to 7.9 log IU/ml after one year. Stored specimens revealed L180M and M204V mutations, 3TC resistance, at our clinic’s initial visit, and a gradual shift from AGC to GGC nucleotides, indicating S202G acquisition over 8 months. Because of no other mutations, TAF/FTC and ETV were initiated, resulting in normalized liver function and declining HBV-DNA levels. Analysis of GenBank HBV/HIV coinfection samples revealed few reports of ETV resistance mutations and no reports of S202G.

Discussion: It is reported the acquisition of HBV multidrug resistance during HBV/HIV coinfection treatment, specifically marking the initial report of S202G acquisition. The reasons for the low number of registrations of ETV resistance of coinfection in GenBank were that coinfection was not specified and that many registrations were from Asia and Africa where ETV has not been used.
Background: Peritoneal tuberculosis (TB) is one of the most challenging forms of extra-pulmonary tuberculosis to diagnose, most common in the developing world because the symptoms and signs of peritoneal TB are nonspecific.

CASE: A 31-year-old female patient presented to the ER with a chief complaint of abdominal pain for the last 2 months, VAS 8/10, associated with lethargic, body weight loss, fever, nausea, vomiting, for 1 months. Her vital sign was stable with the temperature 38.5 C. The laboratory showed Hb 8.6 g/dL, WBC 12,800/mm^3. The blood smear showed microcytic hypochromic anemia causes by chronic disease anemia. Abdominal CT with contrast was performed and showed suggestive peritonitis tuberculosis with peritoneum thickening and minimal ascites. Anti-tuberculosis drugs was planned to be given for 9 months. After 2 months therapy, the symptoms were gradually improving and body weight increases by at least 10 kilograms.

DISCUSSION: Female patients with complaints of abdominal pain can be caused by various diseases, determined based on the symptoms that occur, medical history, and epidemiological data. Peritonitis tuberculosis is one of the differential diagnoses with the most common complaints being abdominal pain (73%) and fever (58%). The complaints are difficult to differentiate from other intra-abdominal diseases, and the major diagnostic unavailable. In this patient, radiologic imaging techniques were the diagnostic basis, and abdominal CT with contrast showed peritoneal thickening. Treatment of peritoneal TB is primarily the anti-TB regimen.

CONCLUSION: Peritoneal tuberculosis has non-specific symptoms and complaints, making diagnosis difficult. A correct diagnosis is desirable.

KEYWORDS: Diagnosis, Peritonitis, Tuberculosis

A RARE CASE OF HIRSCHPRUNG’S DISEASE IN AN ADULT PATIENT: CASE REPORT

Enrico J. A. Marpaung1, Gunawan A. Wibowo2, Christine B. Siregar2

1Mitra Keluarga Hospital Jakarta Indonesia, 2University of Sumatera Utara Medan Indonesia, 3Mitra Keluarga Hospital Jakarta Indonesia

Background: Hirschsprung’s disease is considered a newborn disease, occurs in 1:5000 births, but in adults it is rarely considered and often undiagnosed. A variety of diagnostic tests including contrast enema and anorectal manometry may be used as diagnostic screens, but diagnosis ultimately rests upon histopathological evaluation of a rectal biopsy.

CASE: A 25-year-old male patient presented to the outpatient clinic with chief complaints of abdominal pain for the last 3 months, associated with bloating, nausea, and constipation. He has no similar complaints since birth. Abdominal computed tomography with contrast showed dilatation of the colon, colitis with fat stranding and multiple periodic lymphadenopathy (mainly sigmoid, descending, and transverse colon), fecal material, and minimal ascites was found. The final diagnosis at our hospital was adult hirschprung, diagnosed by the history taking and abdominal computed tomography. The patient was referred to a digestive surgeon for further treatment.

DISCUSSION: Constipation is a common disorder that usually refers to persistent, infrequent defecation, difficult stool passage. This condition can deteriorate into distal colon obstruction, worsening constipation or even acute intestinal obstruction. Barium enema and biopsy are the gold standard. Surgical procedure to removal of the aganglionic segment remains the definitive treatment for this disease.

CONCLUSION: Adult Hirschsprung’s disease should be considered in any young patient presenting with a long-standing history of constipation, although it is rare. Abdominal computed tomography examination is recommended as a useful tool in the suspected diagnosis. Definitive treatment is surgical removal of the agangliconic segment.

KEYWORDS: Abdominal, Adult, Constipation, Hirschprung
within the gallbladder and common bile duct, with intermittent bleeding proximal to the choledochotomy. Histopathology noted varisized blood vessels in the serosa and muscularis layer of the gallbladder, consistent with hemangioma. Six days post operative, hematochezia recurred with sanguinous T-tube output. Angiogram of the right hepatic artery revealed multifocal stenosis with outpouching in the distal A8 branch and embolization was performed. Based on the seven-item diagnostic criteria for PAN and the presence of characteristic beading pattern on angiogram, a diagnosis of PAN was established and hydrocortisone was started.

This case underscores the intricate clinical scenario of PAN presenting as hemobilia, necessitating a heightened level of clinical suspicion and a collaborative medical approach. Early diagnosis and appropriate management are pivotal in mitigating the potentially severe consequences of this unique and significant complication associated with PAN. This case report highlights the rare co-occurrence of PAN and gallbladder hemangioma, which manifested in a rare manner, not previously reported in scientific literature.

Combine hepatectomy and flow modulation surgery for patient with HCC and gastroesophageal varices

Giang Nguyen1, Trong Nguyen1, Hung Nguyen1
1Vietnam National Hospital of Tropical Diseases Hanoi Vietnam

Gastroesophageal varices (GEV) bleeding is a complication of portal hypertension, and usually a contraindication of liver resection. Flow modulation surgery include portosystemic shunt and devascularization combined with splenectomy has been proved to be effective in treat GEB and decrease portal vein pressure in liver transplantation. We present 2 cases HCC with gastroesophageal varices treated by liver resection combined with flow modulation surgery.

Case 1: Patient female, 71 years old, diagnosis: HCC, cirrhosis with fundal gastric varices (GOV 2) and large gastrorenal shunt, thrombocytopenia. We have performed dorsal subsegmentectomy combined with Fundectomy and Periesophagogastroscopy devascularization. She recovered well and was discharged after 14 days.

Case 2: Patient male 47 years old with diagnosis of HCC, recurrent esophageal bleeding (6 times in 2 years despite of NSBB treatment), thrombocytopenia. We have performed dorsal subsegmentectomy combined with Warren shunt. His esophageal varices rebled at POD 9 and treated by EBL. He recover well and was discharged at POD 20.

Conclusion: Liver resection can combine with flow modulation surgery to treat for patient with HCC and GEV

Patients with Hepatosplenic Schistosomiasis who underwent Modified Sugiuira Procedure: A Case Series

EUROPEAN HENLEY SANCHEZ1, CAMILLE NICA SOLAJES1, AARON VELASCO1
1SOUTHERN PHILIPPINES MEDICAL CENTER DAVAO CITY Philippines

Approximately 5% with schistosomiasis develop Hepatosplenic Schistosomiasis (HSS). It encompasses perportal fibrosis, portal hypertension, upper gastrointestinal bleeding (UGIB) due to variceal bleed, and varying degrees of cytopenia and splenomegaly due to hypersplenism that poses significant morbidity and mortality.

From 2019 to 2023, four cases previously diagnosed and managed for Schistosomiasis presented with sudden onset hematemesis. Abdominal imaging studies showed splenomegaly with splenic index ranging from 1358 to 5184, with mass effect and displacement of bowels and left kidney. Laboratories revealed anemia, thrombocytopenia, and prolonged coagulation studies. UGIE showed Esophago-Gastric Varices and then started on Propranolol. Rectal biopsies showed Schistosomal ova. The patients underwent the Modified Sugiuira procedure where post-procedure, all had rebound thrombocytosis controlled with hydroxyurea. Monitoring revealed resolution of anemia, thrombocytopenia and coagulation studies. Only one patient had recurrence of hematemesis controlled with rubber band ligation, and all subsequently had no recurrence of hematemesis. HSS currently has no established guidelines for management. Available data suggest an interplay between medical therapy, variceal interventions, and surgical procedures. Medical management includes praziquantel especially in communities with high levels of transmission to prevent reinfection and Propranolol as primary and secondary prophylaxis for variceal bleeding. For patients with bleeding varices, treatment considerations include rubber band ligation, sclerotherapy, shunt surgical procedures, or devascularization with splenectomy. For patients with secondary hypersplenism, distal splenorenal shunt surgery or esophageal and gastric devascularization with splenectomy are surgical options. Potential benefits with carvedilol, transjugular intrahepatic portosystemic shunt, and spleen preserving procedures are options to be explored for future trials.

Atypical Nutcracker’s Syndrome in Polycystic Liver Disease: A Case Report

Salahuddin Andam1, Rene John D. Febro1, Hyacinth C. Eviota1, Frederick T. Dy1, Alvin Brian C. Velasco1, Rommel P. Romano1, Estrellita J. Ruiz1, Carmelita D. Dalupang1, Jaqueline S. Arsenal1, Erika Johanna P. Tañada1, Maria Hossea C. Monfero1, Stephen N. Wong1
1University of Santo Tomas Hospital Manila Philippines

Background: The formation of esophago-gastric varices is a rare complication of polycystic liver disease (PLD) where the multiplicity of cysts leads to pseudo-cirrhosis and portal hypertension. However, these cysts may also lead to extrinsic vascular compression, wherein the nutcracker syndrome (NCS) is one of the rarest. We report an unusual case of a PLD patient who presented with bleeding gastric varices due to NCS.

Case Presentation: A 67-year-old female with innumerable large hepatic cysts due to PLD presented with a 3-day history of melena. An esophagogastroduodenoscopy revealed a large isolated gastric fundal varix with stigmata of recent bleeding. A total of 1.5 ml. of cyanoacrylate was injected with hemostasis adequately achieved. The patient was sent home with carvedilol. However, patient had recurrence of melena after 1 month. Repeat esophagogastroduodenoscopy showed the same findings with no diminution of the size of the varices. Repeat 2.5 ml. cyanoacrylate injection was successfully performed. A triphasic computed tomography scan of the abdomen showed a non-dilated portal vein but with extrinsic compression of the left renal vein by the superior mesenteric artery, caused by downward pressure from the cysts, leading to the formation of a gastro-renal shunt and gastric varices. A multidisciplinary conference was convened where a comprehensive strategy involving the placement of coils with subsequent
balloon-occluded retrograde transvenous obliteration was offered to the patient.

**Conclusion:** The rare coexistence of PLD and NCS presents substantial challenges in diagnosis and management. An effective multidisciplinary collaboration underscores the significance of a comprehensive approach when addressing this condition.

**Mother to child transmission of HBV - Role of birth-dose and HBIG for prevention**

Nida Ali1,3, John W Ward1, Ehsan Ghani2, Qaiser Hussain3, Muhammad Irfan3

1Coalition for Global Hepatitis Elimination - The Task Force for Global Health Islamabad Pakistan, 3District Health Authority Rawalpindi Pakistan, 4Local Hepatitis Elimination & Prevention - District Health Authority Rawalpindi Pakistan

We report a case of vertical transmission of HBV from the mother to 3/4 of her children and how the child who received neonatal immunoprophylaxis escaped infection. A 26-year-old housewife gave birth to her first child “A” via emergency C-section. She was tested for HBV and HCV as a part of pre-operative screening where she tested negative. During routine antenatal visit to the hospital for her second pregnancy, she tested positive for HBV. The child “S” was given Hepatitis B Birth-dose and Hepatitis B Immunoglobulin (IVIG) right after normal vaginal delivery. She gave birth to the third child “I”, 4 years ago at the hospital. No postpartum intervention for preventing the vertical transmission was done. Frontline workers screened the family and found the mother positive for HBV as well as 3 of the 4 children.

**Conclusion:** The probable source of the mother and the first child “A” acquiring HBV is the C-section surgery. Mother gave birth to 3 more children. The only child who did not acquire the infection was the one who received neonatal immunoprophylaxis. Although during one of the pregnancies, the mother received antiviral tenofovir, it did not prevent the vertical transmission to that child in absence of birth-dose and HBIG.

This highlights the value of antenatal screening and at-birth intervention for preventing the vertical transmission of HBV.

**SUCCESSFUL DOWNSTAGING OF HEPATOCELLULAR CARCINOMA WITH IMMUNOTHERAPY**

DINU ABIRAMI PREM KUMAR1, JOY VARGHESE2, JAYANTHI VENKATARAMAN2

1SENIOR RESIDENT CHENNAI India, 2SENIOR CONSULTANT CHENNAI INDIA

A 63-year-old businessman, from Tamil Nadu, with comorbidities of Diabetes Mellitus, Systemic Hypertension for 20 years and had history of NASH related cirrhosis for 10 years with preserved liver synthetic function (Child A). Patient underwent prophylactic endoscopic variceal ligation twice and has been on beta blockers.

In Dec 2021, he presented with mild right upper quadrant pain, excessive fatigue and weight loss of 10 kgs over two months. On clinical examination, he was stable with no signs of decompen- sation and performance status of 0.

On evaluation, AFP was elevated- 16345 IU/L. CT abdomen revealed ill-defined, 9.2 x 7.5 x 6.3 cm enhancing lesion- Suggestive of HCC.

**Right and main portal venous thrombosis,** Cirrhosis of liver with portal hypertension.

After multidisciplinary team discussion, he underwent Trans arterial chemo embolization and was started on Lenvatinib. Follow up imaging showed stable disease and patient was continued on Lenvatinib. In May 2022, PET CT revealed uptake along the edges of the lesion and patient underwent second TACE. Lenvatinib could not be continued further due to intolerability.

Patient was switched over to immunotherapy with atezolizumab 1200mg and bevacizumab 900mg for 11 cycles once in every three weeks. Following initiation of immunotherapy, AFP reduced gradually from 10820 IU/L to 834 IU/L.

Thus, successful downstaging was achieved in this patient with overall survival till date being 487 days. Patient is continued on immunotherapy and recent PET CT showed no active lesions and no uptake within portal vein thrombus.

**Malignant Hepatic Solitary Fibrous Tumor in a 28- year old Filipino male : A Case Report**

Erika Johanna Tañada1, Stephen N. Wong1, Carmelita D Dalupang1, Rene John D Felbo1, Hyacinth C Eviota,1, Jaqueline S. Arsenal1, Salahuddin C. Andam2, Maria Hossea C. Monfero1

1USTH Manila Philippines

**Background:** Hepatic Solitary fibrous tumor (HSFT) is a rare mesenchymal tumor with few cases reported in literature. Malignant cases of HSFT are even rarer occurrence, and information regarding the optimal management of the disease is currently limited. We present a case of an unresectable malignant giant HSFT in a 28-year old male.

**Case Presentation:** A 28-year old Filipino male with no known co-morbidities sought consult for right upper quadrant pain and weight loss for three months. Whole abdomen ultrasound showed a large predominantly solid mass. Dynamic CT showed a large heterogeneously enhancing mass almost occupying the entire liver with incomplete washout on portovenous and delayed phases. Serum AFP and CA 19-9 were unremarkable. Liver biopsy revealed a poorly differentiated malignancy with epithelioid features. Immunohistochemical staining were positive for CD34 and STAT6 clinching the diagnosis of solitary fibrous tumor. Multidisciplinary approach with referrals to hepatobiliary surgeon and oncologist was done. Tumor was deemed unresectable and patient was offered tyrosine kinase inhibitor for possible downstaging.

**Conclusion:** HSFT is a rare tumor and should be included in the differential diagnosis of liver lesions with atypical imaging findings. The best choice for treatment is complete surgical resection but for massive HSFT with limited hepatic residual volume, strategies to increase the resectability of the tumor is deemed important. More data are needed for unresectable HSFT and long-term follow-up is critical.

**Keywords:** case report; hepatic solitary fibrous tumor;

AN UNUSUAL SYNERGY WITH DEPLETING ENERGY

Deepa Janakiraman¹, Nirmala Dheivamani¹, Sindhuja TA¹, Senthil Kumar R², Winston Thomas¹
¹Department of Paediatric Gastroenterology, MADRAS MEDICAL COLLEGE, INSTITUTE OF CHILD HEALTH, CHENNAI, TAMIL NADU, INDIA CHENNAI India

Introduction: Cryptogenic cirrhosis is now replaced by various genetic diagnoses, considerably bringing down the percentage of cryptogenic cirrhosis from 30% to 9%. Genetic basis should be suspected in multisystem involvement.

CASE REPORT: 12-year-old male child of 3rd degree consanguinity, presented with abdominal distension for one month, jaundice and easy fatigability for 10 days. Child had ascites, mild hepatic encephalopathy, INR 2.5, high SAAG low protein ascites and oesophageal varices on endoscopy suggestive of DCLD with portal-hypertension. Workup for Wilson, autoimmune and infective aetiologies were negative. Child was registered for liver transplantation (LT). But within 15 days of discharge, readmitted with Right Hemiparesis, left UMN facial palsy and bilateral ptosis suggesting nonvascular territory metabolic stroke. MRI showed diffuse diffusion restriction suggesting mitochondrial leukoencephalopathy. ALT was also elevated, hence diagnosis of Mitochondrial DNA Depletion syndrome (MPV17 related) was suspected, further confirmed with exome sequencing and managed with mitochondrial cocktail.

DISCUSSION AND CLINICAL SIGNIFICANCE: Of the 100 MPV17 related hepatonecphalopathy cases reported till date, 96% has infantile onset, while only 4% had childhood onset. None of the childhood onset had liver failure. To our knowledge ours is the 1st case of childhood onset Mitochondrial DNA depletion syndrome-6 with DCLD. Onset of neurological involvement precludes the option of LT for this child.

In the era of genomics, thorough evaluation including genetic testing for definitive aetiology of cryptogenic cirrhosis is warranted before proceeding for LT. In multi-system involvement, especially metabolic stroke with DCLD mitochondrial disease should be considered even in childhood.

A Case Report of Giant Cavernous Hepatic Hemangioma with Kasabach-Merritt Syndrome

Areangela Angeles¹, Jose Gullain E. Cataluna¹, Jemimah P. Fajardo¹
¹St. Luke’s Medical Center, Quezon City Quezon City Philippines

Cavernous hepatic hemangiomas are hypervascular, venous malformations which is considered as the most common benign mesenchymal lesions of the liver. The rate of spontaneous rupture ranges from 1% to 4%, occurring mostly in giant hemangiomas (6-25 cm), with a mortality rate that can reach up to 75%. The operative mortality rate of this complication is around 36.4%.

This is a case of a 22-year-old male with no known co-morbid illness with unremarkable family history and personal social history who presented for progressive sharp and stabbing abdominal pain. Laboratory examination showed anemia (Hgb 8.8), leukocytosis (WBC 10930), thrombocytopenia (58k). Whole Abdominal CT scan with intravenous contrast revealed a large heterogeneously predominantly hypodense exophytic right hepatic lobe mass (14x11.8x16.8cm) with intra luminal mural thrombus. Patient underwent Hepatic Angiogram with Gel and particle embolization of the branches of the right hepatic artery to control the bleeding, and blood transfusion. However, repeat Dynamic CT scan of the liver showed liver enlargement and progression of heterogeneous non-enhancing lobulated exophytic mass lesion (15.3x12.6x19.8 cm previously 14x11.8x16.8 cm) with signs of bleeding and increase in hyperdense fluid collection relating to hemoptoic tumour. Thus, the patient underwent Exploratory laparotomy with Excavation of Intraparenchymal Hematoma, Right Hepatectomy with Cholecystectomy on the background of adequate Functional Liver Reserve by Liver Volumetric Study.

On the third day post operatively, patient developed Pneumonia and recurrent Pleural Effusion with subsequent thoracentesis and pigtail drainage. Medical management resulted to marked improvement of the signs and symptoms and was subsequently discharged well.

A case of HCC with a remarkable response following duvelumab/tremelimumab after systemic therapy

TAKAYOSHI OIKAWA¹, Hidekatsu Kuroda¹, Asami Ito¹, Ippei Nakaya¹, Hiroaki Abe¹, Tamami Abe¹, Akiko Suzuki¹, Kei Endo¹, Yoichi Yoshida¹, Keisuke Kakisaka¹, Akio Miyasaka¹, Takayuki Matsumoto¹
¹Division of Gastroenterology and Hepatology, Department of Internal Medicine, Iwate Medical University Yahaba-cho Japan
**Introduction:** Durvalumab plus tremelimumab (DUR/TRE) is a new first-line treatment that combines immune checkpoint inhibitors for hepatocellular carcinoma (HCC) and is available worldwide. We herein report a case of HCC with a remarkable response to DUR/TRE as fourth-line treatment.

**Case:** A 76-year-old woman with chronic hepatitis B underwent radiofrequency ablation for HCC in 201X. In December 2021, a metastatic nodule was found on the subxiphoid process of the puncture route for ablation therapy. The patient underwent a computed tomography (CT)-guided tumor biopsy for a pathological examination and surgical treatment in February 2022. Subsequently, multiple lung metastases and peritoneal dissemination appeared, and she received sequential treatment with atezolizumab plus bevacizumab, lenvatinib, and sorafenib; however, disease progression was observed. The patient underwent DUR/TRE in April 2023. After three courses of DUR/TRE, a prominent tumor reduction was observed on CT. No adverse events were observed.

**DISCUSSION:** This patient did not respond to anti-PD-L1 antibody or a VEGF inhibitor but did respond to post-treatment DUR/TRE, suggesting that the anti-tumor effect of anti-CTLA-4 antibody was a possible response factor. In addition, the behavior of AFP suggests that tumor shrinkage may have been achieved early in the treatment period.

**Conclusion:** Combination therapy with anti-CTLA-4 antibody may be effective in the post-treatment of patients who have failed systemic treatment with anti-PD-L1 antibody or a multi-tyrosine kinase inhibitor.
